Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · `lfilter`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.lfilter`. Reflected implementation `komorebi_math.signals.recursive.lfilter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RECURSIVE`.

Manifest signature (`s`).

```
(numerator: 'Any', denominator: 'Any', signal: 'Any', *, initial_state: 'Any | None' = None) -> 'FilterOutput'
```

Definition. Apply a finite causal rational filter.

Contract (`D, C, H, R, X`). Numerator and denominator coefficient arrays must be finite and nonempty, and the leading denominator coefficient must be nonzero. Initial state length must equal the normalized filter order. Biquad frequency and quality parameters must satisfy the documented physical range. Streaming execution uses one fixed normalized model until reset.

Guarantees (`E, P, B, K`). The implementation follows direct-form II transposed recursion after denominator normalization. Batch and chunked execution use the same recurrence and therefore agree to numerical precision. Pole-based stability certificates check the finite coefficient model rather than an external plant. Runtime is linear in sample count times filter order, with linear state storage.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · `overlap_add`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.overlap_add`. Reflected implementation `komorebi_math.signals.time_frequency.overlap_add`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (`s`).

```
(frames: 'Any', hop_length: 'int', *, synthesis_window: 'Any | None' = None, length: 'int | None' = None) ->
    ↪ 'np.ndarray'
```

Definition. Overlap and add complete frames with an optional synthesis window.

Contract (`D, C, H, R, X`). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile.

Guarantees (`E, P, B, K`). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · overlap_add_certificate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.overlap_add_certificate`. Reflected implementation `komorebi_math.signals.windows.overlap_add_certificate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WINDOWS`.

Manifest signature (s).

```
(window: 'Any', hop_length: 'int', *, squared: 'bool' = True, require_constant: 'bool' = False, tolerance: 'float'
   ↪  = 1e-12) -> 'Certificate'
```

Definition. Certify nonzero overlap and optionally constant overlap on the shift lattice.

Contract (D, C, H, R, X). Window length and hop values must be positive integers. Parameterized Kaiser and Tukey windows validate their finite parameters. An explicit array must be one-dimensional and have exactly the requested length. Overlap certificates require a compatible shift lattice. Canonical dual construction returns an invalid result when the overlap profile contains a zero.

Guarantees (E, P, B, K). Named windows, gain metrics, overlap profiles, and dual windows are deterministic finite NumPy computations. Certificates state finite overlap or constant-overlap identities to a declared tolerance. Window construction and metric evaluation are linear in window length. Overlap profiles also scale with the number of hop residues.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 31 and Chapter 32.

C.4A · overlap_add_convolve

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.overlap_add_convolve`. Reflected implementation `komorebi_math.signals.fft_convolution.overlap_add_convolve`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FFT-CONVOLUTION`.

Manifest signature (s).

```
(signal: 'Any', kernel: 'Any', *, block_length: 'int' = 1024, mode: 'FIRMode' = 'full') -> 'np.ndarray'
```

Definition. Compute finite convolution through bounded-buffer FFT overlap-add.

Contract (D, C, H, R, X). Signal and kernel arrays must be finite, one-dimensional, and nonempty. FFT and overlap-add execution require a positive block length. The output mode applies the same finite cropping convention as direct convolution. A stateful convolver accepts chunks until `flush()`, emits the remaining tail once, and requires `reset()` before reuse after finalization.

Guarantees (E, P, B, K). Zero-padded FFT convolution and bounded-buffer overlap-add agree with direct finite convolution to numerical precision. The certified wrapper records that comparison. FFT execution reduces the asymptotic cost for long records and kernels to blockwise transform cost, while the stateful object stores the kernel spectrum, overlap tail, and one bounded input buffer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · overlap_profile

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.overlap_profile`. Reflected implementation `komorebi_math.signals.windows.overlap_profile`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WINDOWS`.

Manifest signature (s).

```
(window: 'Any', hop_length: 'int', *, squared: 'bool' = True) -> 'np.ndarray'
```

Definition. Return the infinite-lattice overlap profile indexed by hop residue.

Contract (D, C, H, R, X). Window length and hop values must be positive integers. Parameterized Kaiser and Tukey windows validate their finite parameters. An explicit array must be one-dimensional and have exactly the requested length. Overlap certificates require a compatible shift lattice. Canonical dual construction returns an invalid result when the overlap profile contains a zero.

Guarantees (E, P, B, K). Named windows, gain metrics, overlap profiles, and dual windows are deterministic finite NumPy computations. Certificates state finite overlap or constant-overlap identities to a declared tolerance. Window construction and metric evaluation are linear in window length. Overlap profiles also scale with the number of hop residues.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 31 and Chapter 32.

C.4A · parseval_certificate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.parseval_certificate`. Reflected implementation `komorebi_math.signals.spectral.parseval_certificate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SPECTRAL`.

Manifest signature (s).

```
(signal: 'Any', *, tolerance: 'float' = 1e-12) -> 'Certificate'
```

Definition. Certify the finite NumPy-normalized DFT Parseval identity.

Contract (D, C, H, R, X). Spectral estimators require finite one-dimensional records, a positive sample rate, a valid window and detrending mode, and compatible frame and overlap lengths. Cross spectra require equal-length inputs. One-sided output is reserved for real data. Regularization must be nonnegative and is applied explicitly where transfer ratios would otherwise be singular.

Guarantees (E, P, B, K). Parseval certificates compare the finite NumPy-normalized DFT energy identity. Periodogram and Welch records expose frequency resolution, dominant frequency, and integrated power under the chosen scaling. Cross-spectrum records contain auto spectra, cross spectrum, coherence, and the H1 estimate. Results are numerical finite estimates, not stochastic consistency theorems. FFT cost dominates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · periodogram

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.periodogram`. Reflected implementation `komorebi_math.signals.spectral.periodogram`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SPECTRAL`.

Manifest signature (s).

```
(signal: 'Any', *, sample_rate: 'float' = 1.0, window: 'WindowSpec' = 'boxcar', fft_length: 'int | None' = None,
    ↪ detrend: 'DetrendMode' = 'constant', scaling: 'SpectralScaling' = 'density', onesided: 'bool | None' = None)
    ↪ -> 'PowerSpectrum'
```

Definition. Compute a deterministic finite modified periodogram.

Contract (D, C, H, R, X). Spectral estimators require finite one-dimensional records, a positive sample rate, a valid window and detrending mode, and compatible frame and overlap lengths. Cross spectra require equal-length inputs. One-sided output is reserved for real data. Regularization must be nonnegative and is applied explicitly where transfer ratios would otherwise be singular.

Guarantees (E, P, B, K). Parseval certificates compare the finite NumPy-normalized DFT energy identity. Periodogram and Welch records expose frequency resolution, dominant frequency, and integrated power under the chosen scaling. Cross-spectrum records contain auto spectra, cross spectrum, coherence, and the H1 estimate. Results are numerical finite estimates, not stochastic consistency theorems. FFT cost dominates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · polyphase_convolution

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.polyphase_convolution`. Reflected implementation `komorebi_math.signals.convolution.polyphase_convolution`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(signal: 'Any', kernel: 'Any', order: 'int', *, mode: 'ConvolutionMode' = 'full', tolerance: 'float' = 1e-11) ->
    ↪ 'ComputationResult[np.ndarray]'
```

Definition. Apply a convolution through exact finite polyphase blocks.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · resample_poly

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.resample_poly`. Reflected implementation `komorebi_math.signals.resampling.resample_poly`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'Any', up: 'int', down: 'int', *, taps: 'Any | None' = None, num_taps: 'int | None' = None, window:
    ↪ 'WindowSpec' = ('kaiser', 8.0)) -> 'np.ndarray'
```

Definition. Return centered zero-extension rational polyphase resampling output.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · resample_poly_result

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.resample_poly_result`. Reflected implementation `komorebi_math.signals.resampling.resample_poly_result`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'Any', up: 'int', down: 'int', *, taps: 'Any | None' = None, num_taps: 'int | None' = None, window:
    ↪ 'WindowSpec' = ('kaiser', 8.0), tolerance: 'float' = 1e-12) -> 'ResamplingResult'
```

Definition. Return rationally resampled data with an explicit finite identity certificate.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · resampled_length

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.resampled_length`. Reflected implementation `komorebi_math.signals.resampling.resampled_length`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(input_length: 'int', up: 'int', down: 'int') -> 'int'
```

Definition. Return the finite output length `ceil(input_length * up / down)`.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · spectrogram

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.spectrogram`. Reflected implementation `komorebi_math.signals.time_frequency.spectrogram`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (s).

```
(signal: 'Any', *, scaling: 'SpectrogramScaling' = 'density', **stft_options: 'Any') -> 'SpectrogramResult'
```

Definition. Compute a magnitude, power, spectrum, or density spectrogram.

Contract (D, C, H, R, X). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile.

Guarantees (E, P, B, K). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · status

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.status`. Reflected implementation `komorebi_math.signals.status`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DOMAIN-STATUS`.

Manifest signature (s).

```
() -> komorebi_math.registry.FeatureSpec
```

Definition. Return the registered implementation status for this domain.

Contract (D, C, H, R, X). The feature key is the literal string `signals`. `status()` queries the package registry for that key and returns the registered `FeatureSpec`. The call does not run signal processing, import an optional accelerator, or qualify a backend.

Guarantees (E, P, B, K). The result is deterministic package metadata for the installed source tree. Lookup is constant-time in ordinary Python terms and makes no independent mathematical or numerical claim.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The domain registry path is exercised by the independent verifier for signal foundations. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 4, 31, and 72.

C.4A · stft

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.stft`. Reflected implementation `komorebi_math.signals.time_frequency.stft`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (s).

```
(signal: 'Any', *, sample_rate: 'float' = 1.0, frame_length: 'int' = 256, hop_length: 'int | None' = None,
    ↪ fft_length: 'int | None' = None, window: 'WindowSpec' = 'hann', center: 'bool' = True, pad_end: 'bool' =
    ↪ True, boundary: 'BoundaryMode' = 'zeros', onesided: 'bool | None' = None, detrend: 'DetrendMode' = 'none')
    ↪ -> 'STFTResult'
```

Definition. Compute a finite STFT with metadata sufficient for normalized synthesis.

Contract (D, C, H, R, X). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile.

Guarantees (E, P, B, K). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · stream_fir_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.stream_fir_filter`. Reflected implementation `komorebi_math.signals.filtering.stream_fir_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(signal: 'Any', taps: 'Any', chunk_sizes: 'Iterable[int]', *, tolerance: 'float' = 1e-12) ->
    ↪ 'ComputationResult[np.ndarray]'
```

Definition. Filter a signal by declared chunks and certify causal batch equivalence.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · stream_lfilter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.stream_lfilter`. Reflected implementation `komorebi_math.signals.recursive.stream_lfilter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RECURSIVE`.

Manifest signature (s).

```
(filter_: 'LinearFilter', signal: 'Any', chunk_sizes: 'Any', *, tolerance: 'float' = 1e-12) ->
    ↪ 'ComputationResult[np.ndarray]'
```

Definition. Execute declared chunks and certify equality with one batch recursion.

Contract (D, C, H, R, X). Numerator and denominator coefficient arrays must be finite and nonempty, and the leading denominator coefficient must be nonzero. Initial state length must equal the normalized filter order. Biquad frequency and quality parameters must satisfy the documented physical range. Streaming execution uses one fixed normalized model until reset.

Guarantees (E, P, B, K). The implementation follows direct-form II transposed recursion after denominator normalization. Batch and chunked execution use the same recurrence and therefore agree to numerical precision. Pole-based stability certificates check the finite coefficient model rather than an external plant. Runtime is linear in sample count times filter order, with linear state storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · stream_stft

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.stream_stft`. Reflected implementation `komorebi_math.signals.streaming.stream_stft`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-STREAMING-STFT`.

Manifest signature (s).

```
(signal: 'Any', chunk_sizes: 'Iterable[int]', *, frame_length: 'int' = 256, hop_length: 'int | None' = None,
    ↪ fft_length: 'int | None' = None, window: 'WindowSpec' = 'hann', sample_rate: 'float' = 1.0, onesided: 'bool'
    ↪ = True, detrend: 'DetrendMode' = 'none', pad_end: 'bool' = True, tolerance: 'float' = 1e-11) ->
    ↪ 'ComputationResult[StreamingSTFTBatch]'
```

Definition. Analyze declared chunks and certify equality with the matching batch STFT.

Contract (D, C, H, R, X). A streaming STFT instance fixes its frame, hop, FFT, window, boundary, and sidedness configuration at construction. Chunks must be one-dimensional and compatible with the selected real or complex mode. `flush()` finalizes optional end padding. Processing after finalization is rejected until `reset()` is called. The convenience wrapper requires chunk sizes that cover the supplied record exactly.

Guarantees (E, P, B, K). The processor stores only the unresolved overlap and framing state. Emitted frames are consecutive and use the same transform convention as batch `stft()`. The wrapper certificate compares concatenated streaming output with the matching batch transform to numerical tolerance. Work per emitted frame is one FFT plus bounded buffer movement.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · upsample

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.upsample`. Reflected implementation `komorebi_math.signals.resampling.upsample`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'Any', factor: 'int') -> 'np.ndarray'
```

Definition. Insert `factor - 1` zeros between consecutive finite samples.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · welch_psd

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.welch_psd`. Reflected implementation `komorebi_math.signals.spectral.welch_psd`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SPECTRAL`.

Manifest signature (s).

```
(signal: 'Any', *, sample_rate: 'float' = 1.0, frame_length: 'int' = 256, hop_length: 'int | None' = None,
    ↪ fft_length: 'int | None' = None, window: 'WindowSpec' = 'hann', detrend: 'DetrendMode' = 'constant',
    ↪ scaling: 'SpectralScaling' = 'density', average: 'SpectralAverage' = 'mean', onesided: 'bool | None' = None)
    ↪ -> 'PowerSpectrum'
```

Definition. Average finite modified periodograms over complete overlapping frames.

Contract (D, C, H, R, X). Spectral estimators require finite one-dimensional records, a positive sample rate, a valid window and detrending mode, and compatible frame and overlap lengths. Cross spectra require equal-length inputs. One-sided output is reserved for real data. Regularization must be nonnegative and is applied explicitly where transfer ratios would otherwise be singular.

Guarantees (E, P, B, K). Parseval certificates compare the finite NumPy-normalized DFT energy identity. Periodogram and Welch records expose frequency resolution, dominant frequency, and integrated power under the chosen scaling. Cross-spectrum records contain auto spectra, cross spectrum, coherence, and the H1 estimate. Results are numerical finite estimates, not stochastic consistency theorems. FFT cost dominates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · window_metrics

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.window_metrics`. Reflected implementation `komorebi_math.signals.windows.window_metrics`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WINDOWS`.

Manifest signature (s).

```
(window: 'Any', *, sample_rate: 'float' = 1.0) -> 'WindowMetrics'
```

Definition. Return coherent gain, power gain, and equivalent noise bandwidth.

Contract (D, C, H, R, X). Window length and hop values must be positive integers. Parameterized Kaiser and Tukey windows validate their finite parameters. An explicit array must be one-dimensional and have exactly the requested length. Overlap certificates require a compatible shift lattice. Canonical dual construction returns an invalid result when the overlap profile contains a zero.

Guarantees (E, P, B, K). Named windows, gain metrics, overlap profiles, and dual windows are deterministic finite NumPy computations. Certificates state finite overlap or constant-overlap identities to a declared tolerance. Window construction and metric evaluation are linear in window length. Overlap profiles also scale with the number of hop residues.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 31 and Chapter 32.

Signal foundations reference. The 80 cards in C.4A cover 20 classes, 44 functions, and 16 data exports. Their recorded audit reconciles the manifest and runtime identities with focused tests, independent finite checks, and reference anchors.

C.4B Wavelets, recovery, filter banks, and packet systems: 91 entries

This section documents the public `komorebi_math.signals` research namespace. It covers the adaptive, approximation, denoising, filter-bank, polyphase, recovery, singular-packet, Smith-plane, wavelet, and nonlinear packet contracts that sit above the finite signal substrate documented in C.4A. The cards separate exact index and shape laws from numerical reconstruction certificates and conditional recovery hypotheses.

Contract family	Cards
Adaptive filtering	4
Approximation and threshold localization	5
Wavelet denoising	10
Vector edge recovery	6
Finite and periodic filter banks	11
Nonlinear coefficient packets	3
Polyphase and lattice coordinates	14
Scalar jump recovery	10
Singular packets and retained reconstruction	14
Smith-plane transforms	4
Haar wavelets and packet trees	10
Total	**91**

The boundary remains finite and explicit. A reconstruction certificate compares one implemented finite operator with its declared reference under a stored tolerance. A recovery certificate remains conditional on the smoothness, separation, jump-size, and noise assumptions recorded by the call. Adaptive and denoising results describe the supplied finite records. They do not establish unobserved stochastic convergence or population optimality.

C.4B · `AdaptiveFilterResult`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.AdaptiveFilterResult`. Reflected implementation `komorebi_math.signals.adaptive.AdaptiveFilterResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-ADAPTIVE`.

Manifest signature (`s`).

```
(output: 'np.ndarray', error: 'np.ndarray', final_weights: 'np.ndarray', weight_history: 'np.ndarray', method:
    ↪ 'AdaptiveMethod', certificate: 'Certificate') -> None
```

Definition. Finite adaptive-filter outputs, errors, and coefficient trajectory.

Contract (`D, C, H, R, X`). Adaptive filters require paired finite one-dimensional records of equal nonzero length and a positive tap count. Learning rates, leakage, regularization, forgetting factors, and initialization parameters must satisfy the finite ranges stated by the selected recursion. The result records the full output, error, final coefficients, coefficient history, method label, and finite-run certificate. The certificate does not assert persistent excitation, stochastic convergence, or population optimality. Principal public operations and properties are `mean_squared_error`, `tail_mean_squared_error`.

Guarantees (`E, P, B, K`). LMS and normalized LMS use one bounded coefficient update per sample. RLS also updates a dense inverse-correlation matrix. LMS work scales with sample count times tap count. RLS work scales with sample count times the square of the tap count. Stored coefficient histories scale with sample count times tap count.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal recovery and

filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 34.

C.4B · BestBasisResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.BestBasisResult`. Reflected implementation `komorebi_math.signals.wavelets.BestBasisResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(leaves: 'tuple[str, ...]', cost: 'float', decisions: 'dict[str, str]', margins: 'dict[str, float]', certificate:
   ↪ 'Certificate') -> None
```

Definition. Exact additive best basis result for a finite packet tree.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required. Principal public operations and properties are `reconstruct`, `pruning`.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · BreakpointBandResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.BreakpointBandResult`. Reflected implementation `komorebi_math.signals.recovery.BreakpointBandResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(indices: 'tuple[int, ...]', response: 'np.ndarray', threshold: 'float', noise_amplification: 'float',
   ↪ certificate: 'Certificate') -> None
```

Definition. Finite difference indices whose magnitude exceeds a declared noise band.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · FilterBankReport

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FilterBankReport`. Reflected implementation `komorebi_math.signals.filterbanks.FilterBankReport`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(lower_frame_bound: 'float', upper_frame_bound: 'float', reconstruction_residual: 'float', certificate:
    ↪ 'Certificate') -> None
```

Definition. Finite reconstruction and frame diagnostics for a filter bank.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · FiniteFilterBank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FiniteFilterBank`. Reflected implementation `komorebi_math.signals.filterbanks.FiniteFilterBank`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(analysis_matrix: 'Any', synthesis_matrix: 'Any') -> 'None'
```

Definition. A finite analysis matrix together with a declared synthesis matrix.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract. Principal public operations and properties are `input_dimension`, `coefficient_dimension`, `analyze`, `synthesize`, `reconstruction_operator`, `report`, `canonical_dual`, `perturbation_bound`.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `HaarDecomposition`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.HaarDecomposition`. Reflected implementation `komorebi_math.signals.denoise.HaarDecomposition`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(approximation: 'np.ndarray', details: 'tuple[np.ndarray, ...]', normalized: 'bool', original_length: 'int') ->
    ↪ None
```

Definition. A finite multilevel Haar approximation and ordered detail channels.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk. Principal public operations and properties are `levels`, `reconstruct`, `certificate`.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `HaarFilterBank`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.HaarFilterBank`. Reflected implementation `komorebi_math.signals.filterbanks.HaarFilterBank`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(normalized: 'bool' = True) -> None
```

Definition. Exact pairwise orthonormal Haar analysis and synthesis.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract. Principal public operations and properties are `analyze`, `synthesize`, `certificate`.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost. The provenance registry records `PSC-V-T10` as Orthonormal Haar reconstruction. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `HaarPacketTree`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.HaarPacketTree`. Reflected implementation `komorebi_math.signals.wavelets.HaarPacketTree`. The same runtime object is also available through `komorebi_math.HaarPacketTree`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(signal: 'np.ndarray', depth: 'int', normalized: 'bool', _nodes: 'dict[str, np.ndarray]') -> None
```

Definition. All Haar packet coefficients through one finite binary depth.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required. Principal public operations and properties are `analyze`, `decompose`, `nodes`, `coefficients`, `coefficient`, `paths_at_depth`, `full_leaves`, `validate_pruning`, `reconstruct`, `energy`, `reconstruction_certificate`, `certificate`. Additional public members are recorded in the machine-readable inventory.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels. The provenance registry records `PSC-V-D12` as Finite Haar packet tree. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `JumpDetection`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.JumpDetection`. Reflected implementation `komorebi_math.signals.recovery.JumpDetection`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(cell: 'int', left_position: 'float', right_position: 'float', location: 'float', amplitude: 'float') -> None
```

Definition. One detected jump cell with a midpoint location and contrast estimate.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold

gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `JumpRecoveryResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.JumpRecoveryResult`. Reflected implementation `komorebi_math.signals.recovery.JumpRecoveryResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(detections: 'tuple[JumpDetection, ...]', threshold: 'float', background_bound: 'float', location_error_bound:
   ↪  'float', amplitude_error_bound: 'float', certificate: 'Certificate') -> None
```

Definition. Detected jumps together with theorem scale error bounds.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive. Principal public operations and properties are `cells`, `locations`, `amplitudes`.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `LatticePolyphaseCoordinates`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.LatticePolyphaseCoordinates`. Reflected implementation `komorebi_math.signals.polyphase.LatticePolyphaseCoordinates`. The same runtime object is also available through `komorebi_math.stable.LatticePolyphaseCoordinates`, `komorebi_math.v1.LatticePolyphaseCoordinates`, `komorebi_math.api.v1.LatticePolyphaseCoordinates`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(channels: 'dict[tuple[int, ...], np.ndarray]', strides: 'tuple[int, ...]', original_shape: 'tuple[int, ...]') ->
    ↪ None
```

Definition. Rectangular lattice residue channels of a finite multidimensional array.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride. Principal public operations and properties are `dtype`, `reconstruct`, `refine`, `coarsen`, `certificate`.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients. The provenance registry records `PSC-V-D03` as Rectangular lattice packet coordinates. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · `PacketEstimate1D`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PacketEstimate1D`. Reflected implementation `komorebi_math.signals.approximation.PacketEstimate1D`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-APPROXIMATION`.

Manifest signature (s).

```
(mask: 'np.ndarray', amplitude: 'float', threshold: 'float', certificate: 'Certificate') -> None
```

Definition. One heuristic positive contrast packet estimate.

Contract (D, C, H, R, X). Low-pass approximations require finite nonempty arrays and nonnegative integer mode budgets. The one-dimensional transform retains the declared centered frequency set. The two-dimensional transform retains the declared rectangular centered set. Otsu thresholding requires at least one finite value and two histogram bins. The positive-packet estimator assumes one dominant positive contrast region and is a bounded heuristic rather than a universal edge detector.

Guarantees (E, P, B, K). FFT approximations are deterministic numerical projections for the supplied finite grid and transform convention. Otsu thresholding is a deterministic finite histogram rule. Packet estimates retain their observed interval and reconstruction data together with a heuristic certificate. FFT cost dominates the transform routes. Histogram and scan routes are linear in the input size up to the fixed bin count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · PeriodicFilterBank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PeriodicFilterBank`. Reflected implementation `komorebi_math.signals.filterbanks.PeriodicFilterBank`. The same runtime object is also available through `komorebi_math.PeriodicFilterBank`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(analysis_filters: 'Iterable[Any]', synthesis_filters: 'Iterable[Any]', decimation: 'int') -> 'None'
```

Definition. A finite periodic analysis and synthesis bank with explicit matrices.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract. Principal public operations and properties are `channels`, `analysis_matrix`, `synthesis_matrix`, `analyze`, `synthesize`, `reconstruction_operator`, `perfect_reconstruction_certificate`, `frame_bounds`, `canonical_synthesis_matrix`, `reconstruction_error_bound`.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost. The provenance registry records `PSC-V-D08` as Finite periodic filter bank. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · PeriodicLiftingScheme

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PeriodicLiftingScheme`. Reflected implementation `komorebi_math.signals.filterbanks.PeriodicLiftingScheme`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(predict: 'Any', update: 'Any') -> 'None'
```

Definition. A reversible predict and update lifting scheme on periodic pairs.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract. Principal public operations and properties are `analyze`, `synthesize`, `certificate`.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost. The provenance registry records `PSC-V-T11` as Exact periodic lifting update. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `PolyphaseCoordinates`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PolyphaseCoordinates`. Reflected implementation `komorebi_math.signals.polyphase.PolyphaseCoordinates`. The same runtime object is also available through `komorebi_math.stable.PolyphaseCoordinates`, `komorebi_math.v1.PolyphaseCoordinates`, `komorebi_math.api.v1.PolyphaseCoordinates`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(channels: 'tuple[np.ndarray, ...]', order: 'int', axis: 'int', original_shape: 'tuple[int, ...]') -> None
```

Definition. Residue channels of a finite array along one axis.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride. Principal public operations and properties are `dtype`, `reconstruct`, `channel_lengths`, `refine`, `coarsen`, `certificate`.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients. The provenance registry records `PSC-V-D01` as One dimensional polyphase coordinates. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · `PolyphaseKernel`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PolyphaseKernel`. Reflected implementation `komorebi_math.signals.polyphase.PolyphaseKernel`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(target: 'int', source: 'int', coefficients: 'np.ndarray', order: 'int') -> None
```

Definition. One source to target filter kernel in an infinite polyphase law.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with

omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · PolyphaseSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PolyphaseSystem`. Reflected implementation `komorebi_math.signals.polyphase.PolyphaseSystem`. The same runtime object is also available through `komorebi_math.PolyphaseSystem`, `komorebi_math.stable.PolyphaseSystem`, `komorebi_math.v1.PolyphaseSystem`, `komorebi_math.api.v1.PolyphaseSystem`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(order: 'int', axis: 'int' = -1) -> None
```

Definition. Reusable one axis polyphase analysis and synthesis system.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride. Principal public operations and properties are `analyze`, `synthesize`, `certificate`.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · PrunedPacketCoefficients

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PrunedPacketCoefficients`. Reflected implementation `komorebi_math.signals.wavelets.PrunedPacketCoefficients`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(tree: 'HaarPacketTree', leaves: 'tuple[str, ...]') -> None
```

Definition. Coefficients selected by one complete pruning of a Haar packet tree.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp

exponents must be positive and finite where required. Principal public operations and properties are `coefficients`, `reconstruct`, `energy`, `certificate`.

Guarantees (`E`, `P`, `B`, `K`). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `RetainedPacketReconstruction`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.signals.RetainedPacketReconstruction`. Reflected implementation `komorebi_math.signals.singular_packets.RetainedPacketResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `RetainedPacketResult` resolves to the same runtime object. The public export name maps to implementation object `RetainedPacketResult`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (`s`).

```
(smooth_component: 'np.ndarray', smooth_approximation: 'np.ndarray', packet: 'np.ndarray', reconstruction:
    ↪ 'np.ndarray', error: 'np.ndarray', certificate: 'Certificate', packet_error: 'np.ndarray | None' = None) ->
    ↪ None
```

Definition. A smooth approximation plus an exact or estimated singular packet.

Contract (`D`, `C`, `H`, `R`, `X`). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (`E`, `P`, `B`, `K`). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `RetainedPacketResult`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.signals.RetainedPacketResult`. Reflected implementation `komorebi_math.signals.singular_packets.RetainedPacketResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `RetainedPacketReconstruction` resolves to the same runtime object. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (`s`).

```
(smooth_component: 'np.ndarray', smooth_approximation: 'np.ndarray', packet: 'np.ndarray', reconstruction:
   ↪ 'np.ndarray', error: 'np.ndarray', certificate: 'Certificate', packet_error: 'np.ndarray | None' = None) ->
   ↪ None
```

Definition. A smooth approximation plus an exact or estimated singular packet.

Contract (`D, C, H, R, X`). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (`E, P, B, K`). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `SingularPacket1D`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.SingularPacket1D`. Reflected implementation `komorebi_math.signals.singular_packets.SingularPacket1D`. The same runtime object is also available through `komorebi_math.SingularPacket1D`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (`s`).

```
(components: 'Iterable[TruncatedPowerTerm]') -> 'None'
```

Definition. A finite sum of truncated power terms.

Contract (`D, C, H, R, X`). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity. Principal public operations and properties are `from_jumps`, `evaluate`, `remove`, `restore`, `trace_jumps`.

Guarantees (`E, P, B, K`). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost. The provenance registry records `PSC-V-D16` as Finite one dimensional singular packet. Its recorded status is `definition`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · TruncatedPowerPacket

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.TruncatedPowerPacket`. Reflected implementation `komorebi_math.signals.singular_packets.TruncatedPowerTerm`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `TruncatedPowerTerm` resolves to the same runtime object. The public export name maps to implementation object `TruncatedPowerTerm`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(location: 'float', amplitude: 'complex', order: 'int' = 0) -> None
```

Definition. The term `amplitude * (x - location)_+^order / order!`.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity. Principal public operations and properties are `evaluate`, `location_bound`.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost. The provenance registry records `PSC-V-D15` as Truncated power singular packet. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · TruncatedPowerTerm

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.TruncatedPowerTerm`. Reflected implementation `komorebi_math.signals.singular_packets.TruncatedPowerTerm`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `TruncatedPowerPacket` resolves to the same runtime object. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(location: 'float', amplitude: 'complex', order: 'int' = 0) -> None
```

Definition. The term `amplitude * (x - location)_+^order / order!`.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity. Principal public operations and properties are `evaluate`, `location_bound`.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost. The provenance registry records `PSC-V-D15` as Truncated power singular packet. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · VectorJumpRecoveryResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.VectorJumpRecoveryResult`. Reflected implementation `komorebi_math.signals.edge_recovery.JumpRecoveryResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `JumpRecoveryResult`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-VECTOR-RECOVERY`.

Manifest signature (s).

```
(cells: 'tuple[int, ...]', locations: 'np.ndarray', amplitudes: 'np.ndarray', contrasts: 'np.ndarray', threshold:
   ↪ 'float', background_bound: 'float', location_error_bound: 'float', amplitude_error_bound: 'float',
   ↪ certificate: 'Certificate') -> None
```

Definition. Detected jump cells, locations, amplitudes, and theorem certificate.

Contract (D, C, H, R, X). Vector jump recovery accepts finite scalar or vector samples with at least two sample locations. Spacing and minimum-jump parameters must be positive. Smoothness and noise bounds must be nonnegative. Threshold separation assumptions remain explicit and conditional. Subgaussian wrappers require a positive confidence level strictly below one and return a dimension-aware finite noise bound. Principal public operations and properties are `packet`.

Guarantees (E, P, B, K). Recovery records expose cells, estimated locations, amplitudes, contrasts, and a conditional certificate. Smooth Haar bounds and step coefficients are exact finite formulas under their stated conventions. The recovery guarantee is conditional on the declared smoothness, spacing, separation, and noise hypotheses. Work is linear in the number of candidate cells times the signal dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_recovery.py` and `tests/test_block4_hardening.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · WaveletDenoiseResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.WaveletDenoiseResult`. Reflected implementation `komorebi_math.signals.denoise.WaveletDenoiseResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(signal: 'np.ndarray', decomposition: 'HaarDecomposition', thresholded_details: 'tuple[np.ndarray, ...]',
   ↪ thresholds: 'tuple[float, ...]', noise_sigma: 'float', rule: 'ThresholdRule', mode: 'ThresholdMode',
   ↪ certificate: 'Certificate') -> None
```

Definition. A thresholded Haar reconstruction with explicit finite diagnostics.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk. Principal public operations and properties are `removed_energy`.

Guarantees (`E, P, B, K`). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `best_basis`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.best_basis`. Reflected implementation `komorebi_math.signals.wavelets.best_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (`s`).

```
(tree: 'HaarPacketTree', cost: 'Mapping[str, float] | CostFunction') -> 'BestBasisResult'
```

Definition. Return the exact minimum cost pruning of a finite Haar packet tree.

Contract (`D, C, H, R, X`). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (`E, P, B, K`). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels. The provenance registry records `PSC-V-T14` as Exact additive best basis recursion. Its recorded status is `proved`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `coefficient_packets`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.coefficient_packets`. Reflected implementation `komorebi_math.signals.nonlinear.coefficient_packets`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-NONLINEAR-PACKETS`.

Manifest signature (`s`).

```
(coefficients: 'Sequence[complex]', order: 'int') -> 'tuple[np.ndarray, ...]'
```

Definition. Split a finite coefficient sequence into residue supported packets.

Contract (`D, C, H, R, X`). Coefficient packet construction requires a positive packet order and a finite one-dimensional coefficient record. Packet products require both inputs to use the same flat or nested representation. Channel dimensions must agree with the declared packet order. Nonlinear shift filters require either the supported legacy shift form or paired nonempty shifts and coefficients.

Guarantees (`E, P, B, K`). Packet products implement cyclic channel convolution with the required carry terms and expose a numerical comparison with the direct Cauchy product. Coefficient packets are exact index partitions of

the supplied finite record. Shift filters are deterministic finite sums. Cost follows the number of channels, retained coefficients, and declared shifts.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_extended.py` and `tests/test_block4_hardening.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 28 and 35.

C.4B · `denoising_risk_certificate`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.denoising_risk_certificate`. Reflected implementation `komorebi_math.signals.denoise.denoising_risk_certificate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(clean_signal: 'Any', noisy_signal: 'Any', denoised_signal: 'Any', *, tolerance: 'float' = 0.0) -> 'Certificate'
```

Definition. Compare observed finite squared error before and after denoising.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `detect_piecewise_polynomial_breaks`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.detect_piecewise_polynomial_breaks`. Reflected implementation `komorebi_math.signals.recovery.detect_piecewise_polynomial_breaks`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(samples: 'Sequence[float]', *, degree: 'int', noise_bound: 'float', threshold: 'float | None' = None) ->
    ↪ 'BreakpointBandResult'
```

Definition. Detect the finite bands where a piecewise polynomial may change.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian

bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `difference_noise_bound`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.difference_noise_bound`. Reflected implementation `komorebi_math.signals.singular_packets.difference_noise_bound`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(noise_bound: 'float', order: 'int') -> 'float'
```

Definition. Return the uniform amplification bound `2^order * noise_bound`.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `entropy_cost`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.entropy_cost`. Reflected implementation `komorebi_math.signals.wavelets.entropy_cost`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(coefficients: 'np.ndarray', _: 'str' = '') -> 'float'
```

Definition. Return the Shannon entropy of normalized packet energy.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is

exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `estimate_positive_packet_1d`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.estimate_positive_packet_1d`. Reflected implementation `komorebi_math.signals.approximation.estimate_positive_packet_1d`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-APPROXIMATION`.

Manifest signature (s).

```
(signal: 'np.ndarray | Sequence[float]', *, bins: 'int' = 256) -> 'PacketEstimate1D'
```

Definition. Estimate one positive contrast region by Otsu thresholding.

Contract (D, C, H, R, X). Low-pass approximations require finite nonempty arrays and nonnegative integer mode budgets. The one-dimensional transform retains the declared centered frequency set. The two-dimensional transform retains the declared rectangular centered set. Otsu thresholding requires at least one finite value and two histogram bins. The positive-packet estimator assumes one dominant positive contrast region and is a bounded heuristic rather than a universal edge detector.

Guarantees (E, P, B, K). FFT approximations are deterministic numerical projections for the supplied finite grid and transform convention. Otsu thresholding is a deterministic finite histogram rule. Packet estimates retain their observed interval and reconstruction data together with a heuristic certificate. FFT cost dominates the transform routes. Histogram and scan routes are linear in the input size up to the fixed bin count. The provenance registry records `PSC-V-H01` as Positive contrast two class packet estimator. Its recorded status is `heuristic`. The provenance record notes that this is not a universal edge detector.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `estimate_white_noise_sigma`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.estimate_white_noise_sigma`. Reflected implementation `komorebi_math.signals.denoise.estimate_white_noise_sigma`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(detail_coefficients: 'Any') -> 'float'
```

Definition. Estimate Gaussian white-noise scale from finest Haar details by MAD.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `estimated_packet_reconstruct`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.estimated_packet_reconstruct`. Reflected implementation `komorebi_math.signals.singular_packets.estimated_packet_reconstruct`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(signal: 'Any', estimated_packet: 'Any', approximation_matrix: 'Any', *, tolerance: 'float' = 1e-10) ->
    ↪ 'ComputationResult[np.ndarray]'
```

Definition. Compatibility wrapper returning only the reconstructed signal.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `fft_lowpass_1d`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.fft_lowpass_1d`. Reflected implementation `komorebi_math.signals.approximation.fft_lowpass_1d`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-APPROXIMATION`.

Manifest signature (s).

```
(signal: 'np.ndarray | Sequence[float]', modes: 'int') -> 'np.ndarray'
```

Definition. Keep discrete Fourier modes whose integer frequency has magnitude at most `modes`.

Contract (D, C, H, R, X). Low-pass approximations require finite nonempty arrays and nonnegative integer mode budgets. The one-dimensional transform retains the declared centered frequency set. The two-dimensional transform retains the declared rectangular centered set. Otsu thresholding requires at least one finite value and two histogram

bins. The positive-packet estimator assumes one dominant positive contrast region and is a bounded heuristic rather than a universal edge detector.

Guarantees (E, P, B, K). FFT approximations are deterministic numerical projections for the supplied finite grid and transform convention. Otsu thresholding is a deterministic finite histogram rule. Packet estimates retain their observed interval and reconstruction data together with a heuristic certificate. FFT cost dominates the transform routes. Histogram and scan routes are linear in the input size up to the fixed bin count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `fft_lowpass_2d`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.fft_lowpass_2d`. Reflected implementation `komorebi_math.signals.approximation.fft_lowpass_2d`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-APPROXIMATION`.

Manifest signature (s).

```
(image: 'np.ndarray', cutoff: 'int') -> 'np.ndarray'
```

Definition. Apply a rectangular centered Fourier cutoff to a finite two dimensional array.

Contract (D, C, H, R, X). Low-pass approximations require finite nonempty arrays and nonnegative integer mode budgets. The one-dimensional transform retains the declared centered frequency set. The two-dimensional transform retains the declared rectangular centered set. Otsu thresholding requires at least one finite value and two histogram bins. The positive-packet estimator assumes one dominant positive contrast region and is a bounded heuristic rather than a universal edge detector.

Guarantees (E, P, B, K). FFT approximations are deterministic numerical projections for the supplied finite grid and transform convention. Otsu thresholding is a deterministic finite histogram rule. Packet estimates retain their observed interval and reconstruction data together with a heuristic certificate. FFT cost dominates the transform routes. Histogram and scan routes are linear in the input size up to the fixed bin count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `finite_difference`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.finite_difference`. Reflected implementation `komorebi_math.signals.recovery.finite_difference`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The same spelling appears at `komorebi_math.finite_difference`, but those routes resolve to different objects. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (`s`).

```
(values: 'Sequence[Any]', *, order: 'int' = 1, step: 'int' = 1) -> 'np.ndarray'
```

Definition. Return a forward finite difference of arbitrary positive order and step.

Contract (`D, C, H, R, X`). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (`E, P, B, K`). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `gamma_from_impedance`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.gamma_from_impedance`. Reflected implementation `komorebi_math.signals.smith.gamma_from_impedance`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SMITH`.

Manifest signature (`s`).

```
(impedance: 'ArrayLike') -> 'np.ndarray'
```

Definition. Map normalized impedance values to reflection coefficients by the Cayley transform.

Contract (`D, C, H, R, X`). Smith-plane transforms accept finite complex scalars or arrays and reject poles in their fractional-linear denominators. Phase rotations require a positive integer order and reduce the phase modulo that order. Sensitivity regularization must be nonnegative.

Guarantees (`E, P, B, K`). Impedance and reflection transforms are inverse pointwise Möbius maps away from their poles. Phase rotation is a deterministic unit-modulus action. Sensitivity is evaluated pointwise with the declared regularization. Work and storage are linear in the number of supplied values.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `haar_analyze`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.haar_analyze`. Reflected implementation `komorebi_math.signals.filterbanks.haar_analyze`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(signal: 'Any', *, normalized: 'bool' = True) -> 'tuple[np.ndarray, np.ndarray]'
```

Definition. Split a finite even length signal into one level Haar low and high channels.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `haar_decompose`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_decompose`. Reflected implementation `komorebi_math.signals.denoise.haar_decompose`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(signal: 'Any', levels: 'int', *, normalized: 'bool' = True) -> 'HaarDecomposition'
```

Definition. Compute a complete finite multilevel Haar decomposition.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays. The provenance registry records `KM-DSP-T06` as Finite multilevel Haar reconstruction. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · haar_filter_bank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_filter_bank`. Reflected implementation `komorebi_math.signals.filterbanks.haar_filter_bank`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(length: 'int', *, normalized: 'bool' = True) -> 'FiniteFilterBank'
```

Definition. Construct the finite one level Haar analysis and synthesis matrices.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · haar_lipschitz_bound

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_lipschitz_bound`. Reflected implementation `komorebi_math.signals.recovery.haar_lipschitz_bound`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(lipschitz_constant: 'float', support_length: 'float') -> 'float'
```

Definition. Return the Paper V bound for a smooth Haar coefficient.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · haar_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_matrix`. Reflected implementation `komorebi_math.signals.filterbanks.haar_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(length: 'int', *, normalized: 'bool' = True) -> 'np.ndarray'
```

Definition. Return the finite one level Haar analysis matrix for an even signal length.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · haar_packet_analyze

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_packet_analyze`. Reflected implementation `komorebi_math.signals.wavelets.haar_packet_analyze`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(signal: 'Any', depth: 'int', *, normalized: 'bool' = True) -> 'HaarPacketTree'
```

Definition. Build a complete finite Haar packet tree to the requested depth.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · haar_packet_synthesize

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_packet_synthesize`. Reflected implementation `komorebi_math.signals.wavelets.haar_packet_synthesize`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(tree_or_coefficients: 'HaarPacketTree | PrunedPacketCoefficients', leaves: 'Iterable[PacketPath] | None' = None)
    ↪  -> 'np.ndarray'
```

Definition. Reconstruct a signal from a complete tree or a pruned packet coefficient set.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · haar_step_coefficient

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_step_coefficient`. Reflected implementation `komorebi_math.signals.recovery.haar_step_coefficient`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(amplitude: 'float', support_length: 'float', relative_location: 'float') -> 'float'
```

Definition. Return the magnitude of one normalized Haar coefficient of a step.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · haar_synthesize

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.haar_synthesize`. Reflected implementation `komorebi_math.signals.filterbanks.haar_synthesize`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(low: 'Any', high: 'Any', *, normalized: 'bool' = True) -> 'np.ndarray'
```

Definition. Reconstruct a signal from one level Haar low and high channels.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · half_shift_distance

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.half_shift_distance`. Reflected implementation `komorebi_math.signals.edge_recovery.half_shift_distance`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-VECTOR-RECOVERY`.

Manifest signature (s).

```
(point: 'float', cell_length: 'float') -> 'float'
```

Definition. Return the better distance to a boundary among a grid and its half cell shift.

Contract (D, C, H, R, X). Vector jump recovery accepts finite scalar or vector samples with at least two sample locations. Spacing and minimum-jump parameters must be positive. Smoothness and noise bounds must be nonnegative. Threshold separation assumptions remain explicit and conditional. Subgaussian wrappers require a positive confidence level strictly below one and return a dimension-aware finite noise bound.

Guarantees (E, P, B, K). Recovery records expose cells, estimated locations, amplitudes, contrasts, and a conditional certificate. Smooth Haar bounds and step coefficients are exact finite formulas under their stated conventions. The recovery guarantee is conditional on the declared smoothness, spacing, separation, and noise hypotheses. Work is linear in the number of candidate cells times the signal dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_recovery.py` and `tests/test_block4_hardening.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · impedance_from_gamma

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.impedance_from_gamma`. Reflected implementation `komorebi_math.signals.smith.impedance_from_gamma`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SMITH`.

Manifest signature (s).

```
(gamma: 'ArrayLike') -> 'np.ndarray'
```

Definition. Invert the normalized impedance Cayley transform.

Contract (D, C, H, R, X). Smith-plane transforms accept finite complex scalars or arrays and reject poles in their fractional-linear denominators. Phase rotations require a positive integer order and reduce the phase modulo that order. Sensitivity regularization must be nonnegative.

Guarantees (E, P, B, K). Impedance and reflection transforms are inverse pointwise Möbius maps away from their poles. Phase rotation is a deterministic unit-modulus action. Sensitivity is evaluated pointwise with the declared regularization. Work and storage are linear in the number of supplied values.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · lattice_polyphase_analyze

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.lattice_polyphase_analyze`. Reflected implementation `komorebi_math.signals.polyphase.lattice_polyphase_analyze`. The same runtime object is also available through `komorebi_math.stable.lattice_polyphase_analyze`, `komorebi_math.v1.lattice_polyphase_analyze`, `komorebi_math.api.v1.lattice_polyphase_analyze`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(signal: 'Any', strides: 'Iterable[int]', *, copy: 'bool' = True) -> 'LatticePolyphaseCoordinates'
```

Definition. Split an array into channels indexed by a rectangular lattice quotient.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients. The provenance registry records `PSC-V-T04` as Exact rectangular lattice polyphase decomposition. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · lattice_polyphase_synthesize

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.lattice_polyphase_synthesize`. Reflected implementation `komorebi_math.signals.polyphase.lattice_polyphase_synthesize`. The same runtime object is also available through `komorebi_math.stable.lattice_polyphase_synthesize`, `komorebi_math.v1.lattice_polyphase_synthesize`, `komorebi_math.api.v1.lattice_polyphase_synthesize`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(coordinates: 'LatticePolyphaseCoordinates') -> 'np.ndarray'
```

Definition. Reconstruct an array from rectangular lattice packet coordinates.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · lms_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.lms_filter`. Reflected implementation `komorebi_math.signals.adaptive.lms_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-ADAPTIVE`.

Manifest signature (s).

```
(input_signal: 'Any', desired_signal: 'Any', num_taps: 'int', *, step_size: 'float' = 0.01, leakage: 'float' = 0.0,
    ↪ initial_weights: 'Any | None' = None) -> 'AdaptiveFilterResult'
```

Definition. Run finite real or complex LMS system identification.

Contract (D, C, H, R, X). Adaptive filters require paired finite one-dimensional records of equal nonzero length and a positive tap count. Learning rates, leakage, regularization, forgetting factors, and initialization parameters must satisfy the finite ranges stated by the selected recursion. The result records the full output, error, final coefficients, coefficient history, method label, and finite-run certificate. The certificate does not assert persistent excitation, stochastic convergence, or population optimality.

Guarantees (E, P, B, K). LMS and normalized LMS use one bounded coefficient update per sample. RLS also updates a dense inverse-correlation matrix. LMS work scales with sample count times tap count. RLS work scales with sample count times the square of the tap count. Stored coefficient histories scale with sample count times tap count. The provenance registry records `KM-DSP-D12` as Finite least-mean-squares adaptation. Its recorded status is `classical input`. The provenance record notes that the finite routine does not assert stochastic convergence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant

to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 34.

C.4B · lp_cost

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.lp_cost`. Reflected implementation `komorebi_math.signals.wavelets.lp_cost`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(exponent: 'float') -> 'CostFunction'
```

Definition. Return an additive coefficient cost based on a positive power sum.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · median_absolute_deviation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.median_absolute_deviation`. Reflected implementation `komorebi_math.signals.denoise.median_absolute_deviation`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(values: 'Any', *, center: 'float | None' = None) -> 'float'
```

Definition. Return the finite median absolute deviation from a supplied or median center.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · mixed_radix_address

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.mixed_radix_address`. Reflected implementation `komorebi_math.signals.polyphase.mixed_radix_address`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(digits: 'Iterable[int]', radices: 'Iterable[int]') -> 'int'
```

Definition. Return the least significant first mixed radix address.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · nlms_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.nlms_filter`. Reflected implementation `komorebi_math.signals.adaptive.nlms_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-ADAPTIVE`.

Manifest signature (s).

```
(input_signal: 'Any', desired_signal: 'Any', num_taps: 'int', *, step_size: 'float' = 0.5, epsilon: 'float' =
   ↪ 1e-08, leakage: 'float' = 0.0, initial_weights: 'Any | None' = None) -> 'AdaptiveFilterResult'
```

Definition. Run finite normalized LMS with an explicit denominator floor.

Contract (D, C, H, R, X). Adaptive filters require paired finite one-dimensional records of equal nonzero length and a positive tap count. Learning rates, leakage, regularization, forgetting factors, and initialization parameters must satisfy the finite ranges stated by the selected recursion. The result records the full output, error, final coefficients, coefficient history, method label, and finite-run certificate. The certificate does not assert persistent excitation, stochastic convergence, or population optimality.

Guarantees (E, P, B, K). LMS and normalized LMS use one bounded coefficient update per sample. RLS also updates a dense inverse-correlation matrix. LMS work scales with sample count times tap count. RLS work scales with sample count times the square of the tap count. Stored coefficient histories scale with sample count times tap count. The provenance registry records `KM-DSP-D13` as Finite normalized least-mean-squares adaptation. Its recorded status is `classical input`. The provenance record notes that the finite routine does not assert stochastic convergence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant

to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 34.

C.4B · nonlinear_shift_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.nonlinear_shift_filter`. Reflected implementation `komorebi_math.signals.nonlinear.nonlinear_shift_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-NONLINEAR-PACKETS`.

Manifest signature (s).

```
(signal: 'Sequence[float]', alpha: 'float' = 0.25, *, shift: 'int' = 1, shifts: 'Sequence[int] | None' = None,
    ↪ coefficients: 'Sequence[float] | None' = None) -> 'np.ndarray'
```

Definition. Apply a polynomial shift interaction to a one dimensional signal.

Contract (D, C, H, R, X). Coefficient packet construction requires a positive packet order and a finite one-dimensional coefficient record. Packet products require both inputs to use the same flat or nested representation. Channel dimensions must agree with the declared packet order. Nonlinear shift filters require either the supported legacy shift form or paired nonempty shifts and coefficients.

Guarantees (E, P, B, K). Packet products implement cyclic channel convolution with the required carry terms and expose a numerical comparison with the direct Cauchy product. Coefficient packets are exact index partitions of the supplied finite record. Shift filters are deterministic finite sums. Cost follows the number of channels, retained coefficients, and declared shifts.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_extended.py` and `tests/test_block4_hardening.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 28 and 35.

C.4B · otsu_threshold

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.otsu_threshold`. Reflected implementation `komorebi_math.signals.approximation.otsu_threshold`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-APPROXIMATION`.

Manifest signature (s).

```
(values: 'np.ndarray | Sequence[float]', bins: 'int' = 256) -> 'float'
```

Definition. Return the finite histogram threshold that maximizes between class variance.

Contract (D, C, H, R, X). Low-pass approximations require finite nonempty arrays and nonnegative integer mode budgets. The one-dimensional transform retains the declared centered frequency set. The two-dimensional transform retains the declared rectangular centered set. Otsu thresholding requires at least one finite value and two histogram bins. The positive-packet estimator assumes one dominant positive contrast region and is a bounded heuristic rather than a universal edge detector.

Guarantees (E, P, B, K). FFT approximations are deterministic numerical projections for the supplied finite grid and transform convention. Otsu thresholding is a deterministic finite histogram rule. Packet estimates retain their observed interval and reconstruction data together with a heuristic certificate. FFT cost dominates the transform routes. Histogram and scan routes are linear in the input size up to the fixed bin count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this

contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · overlap_matrix_error

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.overlap_matrix_error`. Reflected implementation `komorebi_math.signals.singular_packets.overlap_matrix_error`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(true_labels: 'Any', true_values: 'Sequence[complex]', estimated_labels: 'Any', estimated_values:
   ↪  'Sequence[complex]', *, p: 'float' = 2.0, tolerance: 'float' = 1e-12) -> 'ComputationResult[float]'
```

Definition. Certify the finite overlap matrix formula for piecewise constant data.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · overlap_partition_lp_error

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.overlap_partition_lp_error`. Reflected implementation `komorebi_math.signals.singular_packets.overlap_partition_lp_error`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(true_values: 'Any', estimated_values: 'Any', overlap_matrix: 'Any', *, p: 'float' = 2.0) -> 'float'
```

Definition. Return the exact piecewise constant error from a region overlap matrix.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and

filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · packet_energy

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.packet_energy`. Reflected implementation `komorebi_math.signals.wavelets.packet_energy`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(tree_or_coefficients: 'HaarPacketTree | PrunedPacketCoefficients', leaves: 'Iterable[PacketPath] | None' = None)
   ↪  -> 'float'
```

Definition. Return total squared coefficient energy for a complete or pruned packet representation.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · packet_product

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.packet_product`. Reflected implementation `komorebi_math.signals.nonlinear.packet_product`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-NONLINEAR-PACKETS`.

Manifest signature (s).

```
(a: 'Any', b: 'Any', order: 'int') -> 'ComputationResult[tuple[np.ndarray, ...]]'
```

Definition. Multiply finite sequences or already separated cyclic packet channels.

Contract (D, C, H, R, X). Coefficient packet construction requires a positive packet order and a finite one-dimensional coefficient record. Packet products require both inputs to use the same flat or nested representation. Channel dimensions must agree with the declared packet order. Nonlinear shift filters require either the supported legacy shift form or paired nonempty shifts and coefficients.

Guarantees (E, P, B, K). Packet products implement cyclic channel convolution with the required carry terms and expose a numerical comparison with the direct Cauchy product. Coefficient packets are exact index partitions of the supplied finite record. Shift filters are deterministic finite sums. Cost follows the number of channels, retained coefficients, and declared shifts. The provenance registry records `PSC-V-T51` as Cyclic product packet law. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_extended.py` and `tests/test_block4_hardening.py`. The independent ver-

ifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 28 and 35.

C.4B · `periodic_five_three_lifting`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.periodic_five_three_lifting`. Reflected implementation `komorebi_math.signals.filterbanks.periodic_five_three_lifting`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FILTER-BANKS`.

Manifest signature (`s`).

```
() -> 'PeriodicLiftingScheme'
```

Definition. Return the floating point periodic five three lifting scheme.

Contract (`D, C, H, R, X`). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (`E, P, B, K`). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `phase_mobius`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.phase_mobius`. Reflected implementation `komorebi_math.signals.smith.phase_mobius`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SMITH`.

Manifest signature (`s`).

```
(impedance: 'ArrayLike', order: 'int', phase: 'int') -> 'np.ndarray'
```

Definition. Apply a cyclic disk rotation pulled back to normalized impedance coordinates.

Contract (`D, C, H, R, X`). Smith-plane transforms accept finite complex scalars or arrays and reject poles in their fractional-linear denominators. Phase rotations require a positive integer order and reduce the phase modulo that order. Sensitivity regularization must be nonnegative.

Guarantees (`E, P, B, K`). Impedance and reflection transforms are inverse pointwise Möbius maps away from their poles. Phase rotation is a deterministic unit-modulus action. Sensitivity is evaluated pointwise with the declared regularization. Work and storage are linear in the number of supplied values.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · polyphase_analyze

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.polyphase_analyze`. Reflected implementation `komorebi_math.signals.polyphase.polyphase_analyze`. The same runtime object is also available through `komorebi_math.polyphase_analyze`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(signal: 'Any', order: 'int', *, axis: 'int' = -1, copy: 'bool' = True) -> 'PolyphaseCoordinates'
```

Definition. Split a finite array into residue channels along `axis`.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients. The provenance registry records `PSC-V-T02` as Exact finite polyphase decomposition. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · polyphase_filter_kernels

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.polyphase_filter_kernels`. Reflected implementation `komorebi_math.signals.polyphase.polyphase_filter_kernels`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(kernel: 'Any', order: 'int') -> 'tuple[tuple[PolyphaseKernel, ...], ...]'
```

Definition. Return the causal kernels `h[Nm + target - source]` for every residue pair.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and

filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · polyphase_roundtrip_certificate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.polyphase_roundtrip_certificate`. Reflected implementation `komorebi_math.signals.polyphase.polyphase_roundtrip_certificate`. The same runtime object is also available through `komorebi_math.stable.polyphase_roundtrip_certificate`, `komorebi_math.v1.polyphase_roundtrip_certificate`, `komorebi_math.api.v1.polyphase_roundtrip_certificate`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(signal: 'Any', order: 'int', *, axis: 'int' = -1, tolerance: 'float' = 1e-12) -> 'ComputationResult[np.ndarray]'
```

Definition. Analyze and reconstruct a finite signal with a numerical certificate.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · polyphase_synthesize

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.polyphase_synthesize`. Reflected implementation `komorebi_math.signals.polyphase.polyphase_synthesize`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(coordinates: 'PolyphaseCoordinates') -> 'np.ndarray'
```

Definition. Reconstruct a finite array from polyphase coordinates.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · `reconstruction_error`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.reconstruction_error`. Reflected implementation `komorebi_math.signals.filterbanks.reconstruction_error`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FILTER-BANKS`.

Manifest signature (s).

```
(bank: 'FiniteFilterBank') -> 'float'
```

Definition. Return the spectral norm of the finite filter bank reconstruction defect.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · `recover_jumps_subgaussian`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.recover_jumps_subgaussian`. Reflected implementation `komorebi_math.signals.recovery.recover_jumps_subgaussian`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(samples: 'Sequence[float]', *, spacing: 'float', lipschitz_bound: 'float', sigma: 'float', delta: 'float',
    ↪ minimum_jump: 'float', threshold: 'float | None' = None, start: 'float' = 0.0, minimum_separation: 'float |
    ↪ None' = None) -> 'JumpRecoveryResult'
```

Definition. Apply the separated jump theorem with a simultaneous sub Gaussian bound.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · recover_separated_jumps

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.recover_separated_jumps`. Reflected implementation `komorebi_math.signals.recovery.recover_separated_jumps`. The same runtime object is also available through `komorebi_math.recover_separated_jumps`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(samples: 'Sequence[float]', *, spacing: 'float', lipschitz_bound: 'float', noise_bound: 'float', minimum_jump:
    ↪ 'float', threshold: 'float | None' = None, start: 'float' = 0.0, minimum_separation: 'float | None' = None)
    ↪ -> 'JumpRecoveryResult'
```

Definition. Recover jump cells by thresholding adjacent sample contrasts.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order. The provenance registry records `PSC-V-T36` as Stable recovery of separated one dimensional jumps. Its recorded status is `conditional theorem`. The provenance record limits the claim to one dimensional sampled signals with separated value jumps.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · recover_vector_jumps

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.recover_vector_jumps`. Reflected implementation `komorebi_math.signals.edge_recovery.recover_jumps`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `recover_jumps`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-VECTOR-RECOVERY`.

Manifest signature (s).

```
(samples: 'Any', *, spacing: 'float', lipschitz_bound: 'float', noise_bound: 'float', minimum_jump: 'float',
    ↪ origin: 'float' = 0.0, threshold: 'float | None' = None) -> 'JumpRecoveryResult'
```

Definition. Recover jump cells by adjacent contrast thresholding.

Contract (D, C, H, R, X). Vector jump recovery accepts finite scalar or vector samples with at least two sample locations. Spacing and minimum-jump parameters must be positive. Smoothness and noise bounds must be nonnegative. Threshold separation assumptions remain explicit and conditional. Subgaussian wrappers require a positive confidence level strictly below one and return a dimension-aware finite noise bound.

Guarantees (E, P, B, K). Recovery records expose cells, estimated locations, amplitudes, contrasts, and a conditional certificate. Smooth Haar bounds and step coefficients are exact finite formulas under their stated conventions. The recovery guarantee is conditional on the declared smoothness, spacing, separation, and noise hypotheses. Work is linear in the number of candidate cells times the signal dimension. The provenance registry records `PSC-V-T19` as Deterministic separated jump cell recovery. Its recorded status is `proved`. The provenance record notes that the result does not certify unknown smoothness or unknown minimum jump size from the samples alone.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_recovery.py` and `tests/test_block4_hardening.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `recover_vector_jumps_subgaussian`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.recover_vector_jumps_subgaussian`. Reflected implementation `komorebi_math.signals.edge_recovery.recover_jumps_subgaussian`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `recover_jumps_subgaussian`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-VECTOR-RECOVERY`.

Manifest signature (s).

```
(samples: 'Any', *, spacing: 'float', lipschitz_bound: 'float', sigma: 'float', minimum_jump: 'float',
    ↪ failure_probability: 'float', origin: 'float' = 0.0) -> 'JumpRecoveryResult'
```

Definition. Apply the deterministic theorem with a simultaneous sub Gaussian noise bound.

Contract (D, C, H, R, X). Vector jump recovery accepts finite scalar or vector samples with at least two sample locations. Spacing and minimum-jump parameters must be positive. Smoothness and noise bounds must be nonnegative. Threshold separation assumptions remain explicit and conditional. Subgaussian wrappers require a positive confidence level strictly below one and return a dimension-aware finite noise bound.

Guarantees (E, P, B, K). Recovery records expose cells, estimated locations, amplitudes, contrasts, and a conditional certificate. Smooth Haar bounds and step coefficients are exact finite formulas under their stated conventions. The recovery guarantee is conditional on the declared smoothness, spacing, separation, and noise hypotheses. Work is linear in the number of candidate cells times the signal dimension. The provenance registry records `PSC-V-T20` as Sub Gaussian jump recovery bound. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_recovery.py` and `tests/test_block4_hardening.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · refinement_children

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.refinement_children`. Reflected implementation `komorebi_math.signals.polyphase.refinement_children`. The same runtime object is also available through `komorebi_math.stable.refinement_children`, `komorebi_math.v1.refinement_children`, `komorebi_math.api.v1.refinement_children`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(coarse_order: 'int', fine_order: 'int', residue: 'int') -> 'tuple[int, ...]'
```

Definition. Return fine residues whose reduction modulo the coarse order is `residue`.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · residue_project

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.residue_project`. Reflected implementation `komorebi_math.signals.polyphase.residue_project`. The same runtime object is also available through `komorebi_math.stable.residue_project`, `komorebi_math.v1.residue_project`, `komorebi_math.api.v1.residue_project`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (s).

```
(signal: 'Any', order: 'int', residue: 'int', *, axis: 'int' = -1) -> 'np.ndarray'
```

Definition. Return the full shaped signal supported on one residue class.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and

filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · retained_packet_reconstruct

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.retained_packet_reconstruct`. Reflected implementation `komorebi_math.signals.singular_packets.retained_packet_reconstruct`. The same runtime object is also available through `komorebi_math.retained_packet_reconstruct`. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(signal: 'Any', packet: 'Any', approximator: 'Callable[[np.ndarray], Any]', *, tolerance: 'float' = 1e-11) ->
    ↪ 'RetainedPacketResult'
```

Definition. Approximate only the packet removed component and restore the packet.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost. The provenance registry records `PSC-V-T17` as Exact retained packet reconstruction identity. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · retained_packet_reconstruction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.retained_packet_reconstruction`. Reflected implementation `komorebi_math.signals.singular_packets.retained_packet_reconstruction`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(signal: 'Any', estimated_packet: 'Any', approximation_matrix: 'Any', *, true_smooth: 'Any | None' = None,
    ↪ true_packet: 'Any | None' = None, tolerance: 'float' = 1e-10) -> 'RetainedPacketResult'
```

Definition. Apply `Q(f - jhat) + jhat` and certify its exact error identity.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · rls_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.rls_filter`. Reflected implementation `komorebi_math.signals.adaptive.rls_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-ADAPTIVE`.

Manifest signature (s).

```
(input_signal: 'Any', desired_signal: 'Any', num_taps: 'int', *, forgetting_factor: 'float' = 0.99, delta: 'float'
   ↪  = 1.0, initial_weights: 'Any | None' = None) -> 'AdaptiveFilterResult'
```

Definition. Run finite real or complex recursive least squares.

Contract (D, C, H, R, X). Adaptive filters require paired finite one-dimensional records of equal nonzero length and a positive tap count. Learning rates, leakage, regularization, forgetting factors, and initialization parameters must satisfy the finite ranges stated by the selected recursion. The result records the full output, error, final coefficients, coefficient history, method label, and finite-run certificate. The certificate does not assert persistent excitation, stochastic convergence, or population optimality.

Guarantees (E, P, B, K). LMS and normalized LMS use one bounded coefficient update per sample. RLS also updates a dense inverse-correlation matrix. LMS work scales with sample count times tap count. RLS work scales with sample count times the square of the tap count. Stored coefficient histories scale with sample count times tap count. The provenance registry records `KM-DSP-D14` as Finite recursive least-squares adaptation. Its recorded status is `classical input`. The provenance record notes that the finite routine does not assert a stochastic identification theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 34.

C.4B · scalar_region_error

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.scalar_region_error`. Reflected implementation `komorebi_math.signals.singular_packets.scalar_region_error`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(true_mask: 'Any', true_value: 'complex', estimated_mask: 'Any', estimated_value: 'complex', *, p: 'float' = 2.0,
   ↪  tolerance: 'float' = 1e-12) -> 'ComputationResult[float]'
```

Definition. Certify the exact empirical overlap formula for two scalar regions.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the

documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `scalar_region_lp_error`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.scalar_region_lp_error`. Reflected implementation `komorebi_math.signals.singular_packets.scalar_region_lp_error`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(true_value: 'complex', estimated_value: 'complex', intersection_measure: 'float', true_only_measure: 'float',
    ↪ estimated_only_measure: 'float', *, p: 'float' = 2.0) -> 'float'
```

Definition. Return the exact scalar region packet error from overlap measures.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `shannon_entropy_cost`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.shannon_entropy_cost`. Reflected implementation `komorebi_math.signals.wavelets.shannon_entropy_cost`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WAVELET-PACKETS`.

Manifest signature (s).

```
(coefficients: 'np.ndarray', path: 'str' = '') -> 'float'
```

Definition. Compatibility alias for `entropy_cost`.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is

exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · smith_sensitivity

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.smith_sensitivity`. Reflected implementation `komorebi_math.signals.smith.smith_sensitivity`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SMITH`.

Manifest signature (s).

```
(gamma: 'ArrayLike', *, regularization: 'float' = 0.0) -> 'np.ndarray'
```

Definition. Return a regularized pointwise sensitivity for the impedance Cayley chart.

Contract (D, C, H, R, X). Smith-plane transforms accept finite complex scalars or arrays and reject poles in their fractional-linear denominators. Phase rotations require a positive integer order and reduce the phase modulo that order. Sensitivity regularization must be nonnegative.

Guarantees (E, P, B, K). Impedance and reflection transforms are inverse pointwise Möbius maps away from their poles. Phase rotation is a deterministic unit-modulus action. Sensitivity is evaluated pointwise with the declared regularization. Work and storage are linear in the number of supplied values.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_extended.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · smooth_haar_coefficient_bound

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.smooth_haar_coefficient_bound`. Reflected implementation `komorebi_math.signals.edge_recovery.smooth_haar_coefficient_bound`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-VECTOR-RECOVERY`.

Manifest signature (s).

```
(lipschitz_bound: 'float', interval_length: 'float') -> 'float'
```

Definition. Return the normalized Haar coefficient bound `M L^(3/2) / 4`.

Contract (D, C, H, R, X). Vector jump recovery accepts finite scalar or vector samples with at least two sample locations. Spacing and minimum-jump parameters must be positive. Smoothness and noise bounds must be nonnegative. Threshold separation assumptions remain explicit and conditional. Subgaussian wrappers require a positive confidence level strictly below one and return a dimension-aware finite noise bound.

Guarantees (E, P, B, K). Recovery records expose cells, estimated locations, amplitudes, contrasts, and a conditional certificate. Smooth Haar bounds and step coefficients are exact finite formulas under their stated conventions. The recovery guarantee is conditional on the declared smoothness, spacing, separation, and noise hypotheses. Work is linear in the number of candidate cells times the signal dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_recovery.py` and `tests/test_block4_hardening.py`. The independent ver-

ifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · `split_mixed_radix_address`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.split_mixed_radix_address`. Reflected implementation `komorebi_math.signals.polyphase.split_mixed_radix_address`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-POLYPHASE`.

Manifest signature (`s`).

```
(address: 'int', radices: 'Iterable[int]') -> 'tuple[int, ...]'
```

Definition. Recover least significant first mixed radix digits.

Contract (`D, C, H, R, X`). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (`E, P, B, K`). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapters 14 and 35.

C.4B · `step_haar_coefficient`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.step_haar_coefficient`. Reflected implementation `komorebi_math.signals.edge_recovery.step_haar_coefficient`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-VECTOR-RECOVERY`.

Manifest signature (`s`).

```
(amplitude: 'float', relative_location: 'float', interval_length: 'float') -> 'float'
```

Definition. Return the magnitude of a normalized Haar coefficient of one step.

Contract (`D, C, H, R, X`). Vector jump recovery accepts finite scalar or vector samples with at least two sample locations. Spacing and minimum-jump parameters must be positive. Smoothness and noise bounds must be nonnegative. Threshold separation assumptions remain explicit and conditional. Subgaussian wrappers require a positive confidence level strictly below one and return a dimension-aware finite noise bound.

Guarantees (`E, P, B, K`). Recovery records expose cells, estimated locations, amplitudes, contrasts, and a conditional certificate. Smooth Haar bounds and step coefficients are exact finite formulas under their stated conventions. The recovery guarantee is conditional on the declared smoothness, spacing, separation, and noise hypotheses. Work is linear in the number of candidate cells times the signal dimension.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_signals_recovery.py` and `tests/test_block4_hardening.py`. The independent ver-

ifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · step_location_lp_error

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.step_location_lp_error`. Reflected implementation `komorebi_math.signals.singular_packets.step_location_lp_error`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SINGULAR-PACKETS`.

Manifest signature (s).

```
(amplitude: 'complex', location: 'float', estimated_location: 'float', *, p: 'float' = 2.0) -> 'float'
```

Definition. Return the exact `L^p` distance between equal amplitude steps.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · subgaussian_noise_bound

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.subgaussian_noise_bound`. Reflected implementation `komorebi_math.signals.recovery.subgaussian_noise_bound`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SCALAR-RECOVERY`.

Manifest signature (s).

```
(sample_count: 'int', sigma: 'float', delta: 'float') -> 'float'
```

Definition. Return the simultaneous adjacent contrast bound used by Paper V.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for signal recovery and filter banks

exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 36.

C.4B · sure_threshold

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.sure_threshold`. Reflected implementation `komorebi_math.signals.denoise.sure_threshold`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(coefficients: 'Any', sigma: 'float') -> 'float'
```

Definition. Return the finite Stein-risk minimizing soft threshold over observed magnitudes.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · threshold_coefficients

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.threshold_coefficients`. Reflected implementation `komorebi_math.signals.denoise.threshold_coefficients`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(coefficients: 'Any', threshold: 'float', *, mode: 'ThresholdMode' = 'soft') -> 'np.ndarray'
```

Definition. Apply hard, soft, or nonnegative-garrote shrinkage coefficientwise.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and

filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · universal_threshold

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.universal_threshold`. Reflected implementation `komorebi_math.signals.denoise.universal_threshold`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(sigma: 'float', coefficient_count: 'int') -> 'float'
```

Definition. Return the classical finite universal threshold `sigma*sqrt(2 log n)`.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

C.4B · wavelet_denoise

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.wavelet_denoise`. Reflected implementation `komorebi_math.signals.denoise.wavelet_denoise`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-DENOISE`.

Manifest signature (s).

```
(signal: 'Any', *, levels: 'int' = 1, mode: 'ThresholdMode' = 'soft', rule: 'ThresholdRule' = 'universal',
    ↪ threshold: 'float | None' = None, sigma: 'float | None' = None, level_dependent: 'bool' = False, normalized:
    ↪ 'bool' = True) -> 'WaveletDenoiseResult'
```

Definition. Denoise a finite signal by thresholding multilevel Haar detail channels.

Contract (D, C, H, R, X). Denoising functions require finite nonempty one-dimensional records. Haar decomposition requires a positive level count and a length divisible by the corresponding power of two. Threshold values and noise scales must be nonnegative. The fixed rule requires an explicit threshold, while universal and SURE rules derive one from the supplied or estimated scale. Risk certificates compare one supplied finite clean reference and do not establish unobserved statistical risk.

Guarantees (E, P, B, K). Normalized Haar analysis preserves finite energy to numerical tolerance. Thresholding is deterministic for the selected mode and rule. Reconstruction uses the stored multilevel coefficient layout. Work is linear in signal length per decomposition and reconstruction pass. Storage is linear in signal length plus the recorded thresholds and coefficient arrays. The provenance registry records `KM-DSP-D10` as Finite Haar coefficient shrinkage.

Its recorded status is `classical input`. The provenance record notes that noise-model optimality is not inferred from one finite signal.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal recovery and filter banks exercises the finite identities, roundtrips, rejection paths, aliases, and implementation ownership relevant to this contract. The source validator for signal recovery and filter banks checks the exact signature, cumulative counts, unique anchor, and preserved prior cards. See Chapter 35.

Signal recovery reference. The 91 cards in C.4B cover 25 classes and 66 functions. Together with C.4A, they document all 171 entries in the signal namespace. Their recorded audit checks the manifest and runtime identities, focused tests, independent finite checks, and reference anchors.

C.5 `komorebi_math.nonlinear`: 149 entries

C.5A Differential calculus, obstruction, lifting, and transport: 80 entries

This section documents the finite nonlinear foundation below packet-jet execution. It covers derivative sources, automatic differentiation adapters, Faà di Bruno composition, nonlinear packet coordinates, obstruction and correction systems, exact prime-power lifting, filtered and graded structures, finite holonomy, and smooth packet transport. The 69 cards in C.5B concern packet jets, sparse tensors, execution plans, GPU boundaries, streaming, profiling, and rooted-tree expansions.

Contract family	Cards
Derivative providers and automatic differentiation	14
Faà di Bruno composition and partition combinatorics	9
Nonlinear coordinates and refinement defects	2
Obstruction, correction, and Schur elimination	14
Filtered correction and spectral sequences	11
Graded operations and Maurer Cartan packets	11
Finite graph holonomy	4
Prime power lifting	8
Smooth packet transport	6
Namespace status	1
Total	**80**

The boundary is deliberately finite. Certificates resolve represented maps, matrices, filtrations, congruences, graphs, and packet families under explicit tolerances or exact finite arithmetic. They do not convert sampled derivatives into global smoothness, finite lift trees into unrestricted p-adic existence, or numerical transport residuals into continuum convergence theorems.

C.5A · `AutomaticDifferentiationProvider`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.nonlinear.AutomaticDifferentiationProvider`. Reflected implementation `komorebi_math.nonlinear.autodiff.AutomaticDifferentiationProvider`. The same runtime object is also available through `komorebi_math.AutomaticDifferentiationProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-AUTODIFF`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', jvp: 'DirectionalJVP', source_dimension: 'int', target_dimension: 'int',
   ↪ max_order: 'int' = 4, exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, name: 'str' = 'automatic
   ↪ differentiation provider') -> None
```

Definition. Framework-neutral higher derivatives obtained by nested JVP calls.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process. Principal public operations and properties are `supports_order`, `value`, `derivative`, `validation_certificate`, `to_dict`.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls. The provenance registry records `PSC-III-N04A` as Directional automatic-differentiation adapter. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 37.

C.5A · `CallableDerivativeProvider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.CallableDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.CallableDerivativeProvider`. The same runtime object is also available through `komorebi_math.CallableDerivativeProvider`, `komorebi_math.beta.CallableDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-DERIVATIVES`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', derivatives: 'Mapping[int, DirectionalDerivative]', source_dimension: 'int',
   ↪ target_dimension: 'int', exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, name: 'str' =
   ↪ 'declared derivative provider') -> None
```

Definition. A map with explicitly supplied directional derivative callables.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `available_orders`, `supports_order`, `value`, `derivative`, `validation_certificate`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-D02` as Declared finite dimensional derivative provider. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus

foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 37 and 38.

C.5A · ComposedDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ComposedDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.composition.ComposedDerivativeProvider`. The same runtime object is also available through `komorebi_math.ComposedDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(outer: 'DerivativeProvider', inner: 'DerivativeProvider', *, name: 'str | None' = None) -> 'None'
```

Definition. Expose a composition as another derivative provider.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records. Principal public operations and properties are `supports_order`, `value`, `derivative`.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded. The provenance registry records `PSC-III-D12` as Composed derivative provider. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · DepthObstructionResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.DepthObstructionResult`. Reflected implementation `komorebi_math.nonlinear.filtered.DepthObstructionResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(depth: 'int', induced_correction_map: 'np.ndarray', defect_coordinates: 'tuple[int, ...]', correction_space:
    ↪ 'ModularLinearSolution', correction_representatives: 'tuple[tuple[int, ...], ...]', certificate:
    ↪ 'Certificate') -> None
```

Definition. One finite filtration-depth obstruction and its correction space.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `vanishes`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabiliza-

tion checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · DerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.DerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.DerivativeProvider`. The same runtime object is also available through `komorebi_math.beta.DerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-DERIVATIVES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Protocol implemented by finite dimensional derivative sources.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `value`, `derivative`, `supports_order`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 37 and 38.

C.5A · DirectRotationResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.DirectRotationResult`. Reflected implementation `komorebi_math.nonlinear.transport.DirectRotationResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SMOOTH-TRANSPORT`.

Manifest signature (s).

```
(unitary: 'np.ndarray', minimum_singular_value: 'float', certificate: 'Certificate') -> None
```

Definition. Polar direct rotation between two nearby packet systems.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet

transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_transport.py` and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 40 and 44.

C.5A · DirectionalDerivative

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.DirectionalDerivative`. Reflected implementation `collections.abc.Callable`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `Callable`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-DERIVATIVES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Callable type alias for one finite directional derivative evaluator.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 37 and 38.

C.5A · DirectionalJVP

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.DirectionalJVP`. Reflected implementation `komorebi_math.nonlinear.autodiff.DirectionalJVP`. The same runtime object is also available through `komorebi_math.DirectionalJVP`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-AUTODIFF`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. One forward-mode Jacobian-vector product primitive.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework

availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 37.

C.5A · DividedSquareResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.DividedSquareResult`. Reflected implementation `komorebi_math.nonlinear.graded.DividedSquareResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(equations: 'dict[str, Any]', reconstructed: 'Any', direct: 'Any', certificate: 'Certificate') -> None
```

Definition. Packet divided-square equations and direct reconstruction result.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · FaaDiBrunoResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FaaDiBrunoResult`. Reflected implementation `komorebi_math.nonlinear.composition.FaaDiBrunoResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(value: 'Any', terms: 'tuple[FaaDiBrunoTerm, ...]', raw_term_count: 'int', evaluated_term_count: 'int',
    ↪ pruned_term_count: 'int', certificate: 'Certificate') -> None
```

Definition. A higher composition value with term and validation records.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · FaaDiBrunoTerm

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FaaDiBrunoTerm`. Reflected implementation `komorebi_math.nonlinear.composition.FaaDiBrunoTerm`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(partition: 'Partition', intermediate_packets: 'tuple[str, ...]', value: 'Any', pruned: 'bool' = False, reason:
   ↪  'str' = '') -> None
```

Definition. One classical or packet-labeled composition term.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records. Principal public operations and properties are `to_dict`.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · FilteredCorrectionProblem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FilteredCorrectionProblem`. Reflected implementation `komorebi_math.nonlinear.filtered.FilteredCorrectionProblem`. The same runtime object is also available through `komorebi_math.FilteredCorrectionProblem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(source: 'FilteredVectorSpace', target: 'FilteredVectorSpace', correction_map: 'Any', defect: 'Any', depth: 'int')
   ↪  -> 'None'
```

Definition. One associated-graded correction problem over a prime field.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a

time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `induced_map`, `solve`.

Guarantees (`E`, `P`, `B`, `K`). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions. The provenance registry records `PSC-III-T51` as One-step filtered lifting criterion. Its recorded status is `proved`.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · `FilteredSpectralSequenceResult`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.nonlinear.FilteredSpectralSequenceResult`. Reflected implementation `komorebi_math.nonlinear.filtered.FilteredSpectralSequenceResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (`s`).

```
(pages: 'tuple[SpectralSequencePage, ...]', total_cohomology_dimensions: 'dict[int, int]', limiting_dimensions:
   ↪ 'dict[int, int]', certificate: 'Certificate') -> None
```

Definition. Finite spectral-sequence pages and limiting dimension comparison.

Contract (`D`, `C`, `H`, `R`, `X`). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (`E`, `P`, `B`, `K`). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · `FilteredVectorSpace`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.nonlinear.FilteredVectorSpace`. Reflected implementation `komorebi_math.nonlinear.filtered.FilteredVectorSpace`. The same runtime object is also available through `komorebi_math.FilteredVectorSpace`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(dimension: 'int', levels: 'Mapping[int, Any]', *, prime: 'int') -> 'None'
```

Definition. A finite decreasing filtration `F^0 V >= ... >= F^N V = 0`.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `from_weights`, `basis`, `dimension_at`, `contains`, `graded_basis`, `graded_dimension`, `graded_coordinates`, `lift_graded`, `certificate`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions. The provenance registry records `PSC-III-D50` as Finite decreasing filtration over a prime field. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · FiniteAbelianGroup

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FiniteAbelianGroup`. Reflected implementation `komorebi_math.nonlinear.graded.FiniteAbelianGroup`. The same runtime object is also available through `komorebi_math.FiniteAbelianGroup`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(labels: 'Sequence[str]', addition: 'Mapping[tuple[str, str], str]', *, zero: 'str', validate: 'bool' = True) ->
    ↪ 'None'
```

Definition. A finite abelian group represented by an explicit addition table.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes. Principal public operations and properties are `cyclic`, `add`, `sum`, `inverse`, `certificate`, `to_dict`.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred. The provenance registry records `PSC-III-D17` as Finite abelian grading group. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · FiniteDifferenceDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FiniteDifferenceDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.FiniteDifferenceDerivativeProvider`. The same runtime object is also available through `komorebi_math.FiniteDifferenceDerivativeProvider`, `komorebi_math.beta.FiniteDifferenceDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-DERIVATIVES`.

Manifest signature (s).

```
(function: 'Callable[[np.ndarray], Any]', source_dimension: 'int', target_dimension: 'int', step: 'float' =
    ↪ 0.0001, max_order: 'int' = 4, name: 'str' = 'central finite difference provider', exactness: 'Exactness' =
    ↪ <Exactness.NUMERICAL: 'numerical'>) -> None
```

Definition. Numerical directional derivatives by recursive central differences.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `supports_order`, `value`, `derivative`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-N03` as Recursive central directional differences. Its recorded status is `finite certificate`. The provenance record notes that roundoff and truncation error grow with derivative order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 37 and 38.

C.5A · FiniteFilteredBranchResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FiniteFilteredBranchResult`. Reflected implementation `komorebi_math.nonlinear.filtered.FiniteFilteredBranchResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(approximations: 'tuple[tuple[int, ...], ...]', limit: 'tuple[int, ...]', exact_solution: 'bool', certificate:
    ↪ 'Certificate') -> None
```

Definition. Compatibility result for a branch through a terminal finite filtration.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · FiniteFilteredCochainComplex

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FiniteFilteredCochainComplex`. Reflected implementation `komorebi_math.nonlinear.filtered.FiniteFilteredCochainComplex`. The same runtime object is also available through `komorebi_math.FiniteFilteredCochainComplex`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(dimensions: 'Mapping[int, int]', differentials: 'Mapping[int, Any]', filtrations: 'Mapping[int,
    ↪ FilteredVectorSpace]', *, prime: 'int') -> 'None'
```

Definition. An exact filtered cochain complex over a prime field.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `differential`, `page`, `total_cohomology_dimensions`, `spectral_sequence`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions. The provenance registry records `PSC-III-S54` as Spectral sequence of a finite filtered complex. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · FiniteLiftTree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FiniteLiftTree`. Reflected implementation `komorebi_math.nonlinear.lifting.FiniteLiftTree`. The same runtime object is also available through `komorebi_math.FiniteLiftTree`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(prime: 'int', levels: 'tuple[tuple[LiftTreeNode, ...], ...]') -> None
```

Definition. A finite prefix of a prime power lift tree.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `max_depth`, `terminal_branches`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · FundamentalHolonomy

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FundamentalHolonomy`. Reflected implementation `komorebi_math.nonlinear.holonomy.FundamentalHolonomy`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-HOLONOMY`.

Manifest signature (s).

```
(edge_index: 'int', source: 'str', target: 'str', matrix: 'Any') -> None
```

Definition. One edge outside the tree and its based cycle holonomy.

Contract (D, C, H, R, X). A transport graph requires a finite vertex set and directed edges carrying compatible square matrices. Path transport requires composable endpoints. Gluing and intertwining checks require a chosen root and finite tolerance. Fundamental holonomy is computed from the selected spanning structure and recorded edges outside the tree.

Guarantees (E, P, B, K). The graph routines compute exact path products for exact input matrices or numerical products otherwise. Certificates compare finite cycle transports, root gauges, and intertwining residuals. The result describes the supplied finite graph. It is not a continuum connection or topological classification without additional hypotheses.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_holonomy.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · GradedConvolutionResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.GradedConvolutionResult`. Reflected implementation `komorebi_math.nonlinear.graded.GradedConvolutionResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(output_label: 'str', value: 'Any', direct_value: 'Any', terms: 'tuple[GradedConvolutionTerm, ...]', certificate:
    ↪ 'Certificate') -> None
```

Definition. Packet-resolved graded convolution and direct reconstruction result.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · GradedConvolutionTerm

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.GradedConvolutionTerm`. Reflected implementation `komorebi_math.nonlinear.graded.GradedConvolutionTerm`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(input_labels: 'tuple[str, ...]', value: 'Any') -> None
```

Definition. One labeled input contribution to a graded packet convolution.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · GradedPacketOperation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.GradedPacketOperation`. Reflected implementation `komorebi_math.nonlinear.graded.GradedPacketOperation`. The same runtime object is also available through `komorebi_math.GradedPacketOperation`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', packets: 'PacketSystem', arity: 'int', operation: 'GradedOperationCallable', *,
   ↪ exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance: 'float | None' = None, name: 'str' =
   ↪ 'graded packet operation') -> 'None'
```

Definition. A multilinear operation tested against a finite packet grading.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes. Principal public operations and properties are `evaluate`, `grading_certificate`, `packet_convolution`.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite

Maurer Cartan series is inferred. The provenance registry records `PSC-III-T18` as Graded packet convolution. Its recorded status is `proved`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · `GradingCertificate`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.GradingCertificate`. Reflected implementation `komorebi_math.nonlinear.graded.GradingCertificate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (`s`).

```
(arity: 'int', tested_input_labels: 'int', forbidden_residual: 'float', certificate: 'Certificate') -> None
```

Definition. Finite certificate that a multilinear operation respects the grading.

Contract (`D, C, H, R, X`). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (`E, P, B, K`). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · `HiddenSolveResult`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.HiddenSolveResult`. Reflected implementation `komorebi_math.nonlinear.elimination.HiddenSolveResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SCHUR-ELIMINATION`.

Manifest signature (`s`).

```
(hidden: 'np.ndarray', point: 'np.ndarray', residual: 'float', iterations: 'int', certificate: 'Certificate') ->
    ↪ None
```

Definition. Finite hidden-variable solve with residual and iteration certificate.

Contract (`D, C, H, R, X`). Nonlinear Schur elimination requires retained and hidden derivative providers with a declared split of visible and hidden coordinates. The hidden derivative at the base point must be square and numerically invertible. Hidden solves require an initial point, a finite iteration limit, and a positive tolerance.

Guarantees (`E, P, B, K`). The first derivative contract implements the finite implicit derivative and reduced Schur derivative. The second derivative contract applies the declared provider derivatives through order two. Exact symbolic inputs may retain exact matrices. Numerical inputs receive residual certificates tied to the selected solve and base point. These are local finite statements, not global existence claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · `HigherMaurerCartanResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.HigherMaurerCartanResult`. Reflected implementation `komorebi_math.nonlinear.graded.HigherMaurerCartanResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(equations: 'dict[str, Any]', reconstructed: 'Any', direct: 'Any', max_order: 'int', certificate: 'Certificate')
   ↪  -> None
```

Definition. Truncated higher packet equations through a declared maximum order.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · `HilbertObstructionProjector`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.HilbertObstructionProjector`. Reflected implementation `komorebi_math.nonlinear.correction.HilbertObstructionProjector`. The same runtime object is also available through `komorebi_math.HilbertObstructionProjector`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (s).

```
(correction_map: 'Any', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Moore–Penrose correction and orthogonal cokernel projection.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point. Principal public operations and properties are `solve`.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and

use storage quadratic in the ambient dimensions. The provenance registry records `PSC-III-T31` as Orthogonal Hilbert obstruction projector. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · `HilbertObstructionResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.HilbertObstructionResult`. Reflected implementation `komorebi_math.nonlinear.correction.HilbertObstructionResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (s).

```
(obstruction: 'np.ndarray', obstruction_norm: 'float', vanishes: 'bool', least_norm_correction: 'np.ndarray |
   ↪ None', correction_residual: 'float', certificate: 'Certificate') -> None
```

Definition. Finite orthogonal obstruction projection and least-norm correction data.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · `IntertwiningResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.IntertwiningResult`. Reflected implementation `komorebi_math.nonlinear.holonomy.IntertwiningResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-HOLONOMY`.

Manifest signature (s).

```
(intertwiners: 'Mapping[str, Any]', edge_residuals: 'Mapping[str, float]', cycle_residuals: 'Mapping[str, float]',
   ↪ certificate: 'Certificate') -> None
```

Definition. Vertex intertwiners propagated along a spanning tree.

Contract (D, C, H, R, X). A transport graph requires a finite vertex set and directed edges carrying compatible square matrices. Path transport requires composable endpoints. Gluing and intertwining checks require a chosen root and finite tolerance. Fundamental holonomy is computed from the selected spanning structure and recorded edges outside the tree.

Guarantees (E, P, B, K). The graph routines compute exact path products for exact input matrices or numerical products otherwise. Certificates compare finite cycle transports, root gauges, and intertwining residuals. The result

describes the supplied finite graph. It is not a continuum connection or topological classification without additional hypotheses.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_holonomy.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · JaxDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.JaxDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.autodiff.JaxDerivativeProvider`. The same runtime object is also available through `komorebi_math.JaxDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-AUTODIFF`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', max_order: 'int' = 4, dtype:
    ↪ 'str | None' = None, name: 'str' = 'JAX derivative provider', exactness: 'Exactness' = <Exactness.NUMERICAL:
    ↪ 'numerical'>) -> None
```

Definition. Nested `jax.jvp` derivatives with lazy framework import.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process. Principal public operations and properties are `available`, `value`, `derivative`, `to_dict`.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls. The provenance registry records `PSC-III-N04J` as Lazy JAX derivative adapter. Its recorded status is `finite certificate`. The provenance record notes that device and precision behavior are controlled by the external JAX runtime.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 37.

C.5A · KatoTransport

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.KatoTransport`. Reflected implementation `komorebi_math.nonlinear.transport.KatoTransport`. The same runtime object is also available through `komorebi_math.KatoTransport`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SMOOTH-TRANSPORT`.

Manifest signature (`s`).

```
(system: 'MovingPacketSystem') -> 'None'
```

Definition. Numerical finite Kato transport for a moving packet system.

Contract (`D, C, H, R, X`). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance. Principal public operations and properties are `evolve`, `direct_rotation_product`, `refinement_certificate`.

Guarantees (`E, P, B, K`). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates. The provenance registry records `PSC-III-T58` as Finite smooth packet transport. Its recorded status is `proved`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_transport.py` and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 40 and 44.

C.5A · `LiftStepResult`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.LiftStepResult`. Reflected implementation `komorebi_math.nonlinear.lifting.LiftStepResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-LIFTING`.

Manifest signature (`s`).

```
(prime: 'int', depth: 'int', point: 'tuple[int, ...]', residual: 'tuple[int, ...]', correction_space:
   ↪ 'ModularLinearSolution', children: 'tuple[tuple[int, ...], ...]', certificate: 'Certificate') -> None
```

Definition. One depth obstruction and all finite correction branches.

Contract (`D, C, H, R, X`). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `lifts`.

Guarantees (`E, P, B, K`). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `LiftTreeNode`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.LiftTreeNode`. Reflected implementation `komorebi_math.nonlinear.lifting.LiftTreeNode`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(value: 'tuple[int, ...]', depth: 'int', parent_index: 'int | None') -> None
```

Definition. One congruence class in a finite prime power lift tree.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `LinearLiftProblem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.LinearLiftProblem`. Reflected implementation `komorebi_math.nonlinear.lifting.LinearLiftProblem`. The same runtime object is also available through `komorebi_math.LinearLiftProblem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(matrix: 'Any', rhs: 'Any', point: 'Any', *, prime: 'int', depth: 'int') -> 'None'
```

Definition. Lift a linear congruence one prime power at a time.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `step`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit. The provenance registry records `PSC-III-T28` as One step lifting criterion. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `LinearObstructionProblem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.LinearObstructionProblem`. Reflected implementation `komorebi_math.nonlinear.obstruction.LinearObstructionProblem`. The same runtime object is also available through `komorebi_math.LinearObstructionProblem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-OBSTRUCTION`.

Manifest signature (`s`).

```
(correction_map: 'Any', defect: 'Any', *, backend: 'str | LinearAlgebraBackend | None' = None, tolerance: 'float' =
   ↪ 1e-10) -> 'None'
```

Definition. Compute the obstruction to solving `D u = -defect`.

Contract (`D, C, H, R, X`). A linear obstruction problem requires a finite matrix and a target residual of matching dimension. The obstruction square additionally requires compatible maps whose two routes can be compared. Tolerances must be positive and finite when numerical rank decisions are used. Principal public operations and properties are `solve`.

Guarantees (`E, P, B, K`). The solver separates the residual into a least squares range component and a cokernel obstruction component. The correction is accepted only when the obstruction norm is within tolerance. Certificates record residuals and rank information for the supplied finite matrix. They do not establish exact vanishing outside the represented arithmetic and tolerance model. The provenance registry records `PSC-III-D13` as Linear correction datum and cokernel obstruction. Its recorded status is `definition`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_obstruction.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `LyapunovSchmidtDecomposition`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.LyapunovSchmidtDecomposition`. Reflected implementation `komorebi_math.nonlinear.correction.LyapunovSchmidtDecomposition`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (`s`).

```
(linearization: 'np.ndarray', kernel_basis: 'np.ndarray', complement_basis: 'np.ndarray', range_basis:
   ↪ 'np.ndarray', obstruction_basis: 'np.ndarray', rank: 'int', certificate: 'Certificate') -> None
```

Definition. Resolved kernel, range, complement, and obstruction spaces.

Contract (`D, C, H, R, X`). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point.

Guarantees (`E, P, B, K`). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · LyapunovSchmidtPoint

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.LyapunovSchmidtPoint`. Reflected implementation `komorebi_math.nonlinear.correction.LyapunovSchmidtPoint`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (s).

```
(kernel_coordinates: 'np.ndarray', complement_coordinates: 'np.ndarray', point: 'np.ndarray', reduced_obstruction:
    ↪ 'np.ndarray', range_residual: 'float', iterations: 'int', certificate: 'Certificate') -> None
```

Definition. One computed point on a finite Lyapunov–Schmidt branch.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · LyapunovSchmidtReduction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.LyapunovSchmidtReduction`. Reflected implementation `komorebi_math.nonlinear.correction.LyapunovSchmidtReduction`. The same runtime object is also available through `komorebi_math.LyapunovSchmidtReduction`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', base_point: 'Any', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Numerical SVD realization of local Lyapunov–Schmidt reduction.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point. Principal public operations and properties are `solve_range`, `base_derivative_certificate`, `reduced_second_derivative`.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions. The provenance registry records `PSC-III-T33` as Finite local Lyapunov–Schmidt reduction. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · MaurerCartanResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.MaurerCartanResult`. Reflected implementation `komorebi_math.nonlinear.graded.MaurerCartanResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GRADED`.

Manifest signature (s).

```
(equations: 'dict[str, Any]', reconstructed: 'Any', direct: 'Any', certificate: 'Certificate') -> None
```

Definition. Finite packet Maurer–Cartan equations and reconstruction certificate.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · ModularLinearSolution

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ModularLinearSolution`. Reflected implementation `komorebi_math.nonlinear.lifting.ModularLinearSolution`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(prime: 'int', solvable: 'bool', particular: 'tuple[int, ...] | None', kernel_basis: 'tuple[tuple[int, ...],
   ↪ ...]', pivot_columns: 'tuple[int, ...]', obstruction_rows: 'tuple[int, ...]') -> None
```

Definition. The affine solution space of a linear system over a prime field.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `nullity`, `solution_count`, `enumerate`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · MovingPacketSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.MovingPacketSystem`. Reflected implementation `komorebi_math.nonlinear.transport.MovingPacketSystem`. The same runtime object is also available through `komorebi_math.MovingPacketSystem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SMOOTH-TRANSPORT`.

Manifest signature (s).

```
(projectors: 'Callable[[float], Iterable[Any]]', derivatives: 'Callable[[float], Iterable[Any]]', *, tolerance:
    ↪  'float' = 1e-09, reference_time: 'float' = 0.0) -> 'None'
```

Definition. A differentiable finite family of complete orthogonal projectors.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance. Principal public operations and properties are `packets`, `packet_derivatives`, `derivative_certificate`, `canonical_generator`, `generator_certificate`.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates. The provenance registry records `PSC-III-D56` as Smooth finite packet system. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_transport.py` and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 40 and 44.

C.5A · NonlinearPacketMap

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.NonlinearPacketMap`. Reflected implementation `komorebi_math.nonlinear.coordinates.NonlinearPacketMap`. The same runtime object is also available through `komorebi_math.NonlinearPacketMap`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-NONLINEAR-COORDINATES`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', source: 'PacketSystem', target: 'PacketSystem', name: 'str' = 'nonlinear packet
    ↪  map') -> None
```

Definition. A nonlinear map evaluated through exact packet analysis and synthesis.

Contract (D, C, H, R, X). A nonlinear packet map requires a callable finite map and compatible finite source and target packet systems. Inputs must have the source ambient dimension. Packet evaluation projects the input into declared source channels, evaluates the map, and resolves the output through the target packet family. Principal public operations and properties are `apply`, `certificate`, `iterate`, `fixed_point_residual`.

Guarantees (E, P, B, K). For a complete target packet system, the recorded packet outputs reconstruct the direct finite map value within the certificate tolerance. The certificate concerns one supplied input and one implemented packet decomposition. It does not imply global linearity, smoothness, or invertibility. Work is dominated by packet projection and one map evaluation. The provenance registry records `PSC-III-D01` as Nonlinear packet coordinate map. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_coordinates_defects.py`. The independent verifier for nonlinear calculus

foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · NonlinearRefinementDefect

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.NonlinearRefinementDefect`. Reflected implementation `komorebi_math.nonlinear.defects.NonlinearRefinementDefect`. The same runtime object is also available through `komorebi_math.NonlinearRefinementDefect`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-REFINEMENT-DEFECTS`.

Manifest signature (s).

```
(fine_map: 'Callable[[Any], Any]', coarse_map: 'Callable[[Any], Any]', coarsen_source: 'Any', coarsen_target:
   ↪  'Any') -> None
```

Definition. Pointwise defect `C_Y F_f(x) - F_c(C_X x)`.

Contract (D, C, H, R, X). A nonlinear refinement defect requires fine and coarse maps together with finite source and target coarsening operators of compatible shape. Iterated bounds additionally require a nonnegative iteration count and a coarse Lipschitz bound supplied by the caller. Principal public operations and properties are `evaluate`, `norm`, `composition_identity`, `iterated_orbit_bound`, `fixed_point_bound`.

Guarantees (E, P, B, K). The direct defect is the finite discrepancy between coarsening after the fine map and applying the coarse map after source coarsening. Orbit estimates are conditional on the supplied Lipschitz constant and measured finite defects. They do not independently prove a global contraction property. The provenance registry records `PSC-III-D10` as Nonlinear refinement defect. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_coordinates_defects.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · NonlinearSchurElimination

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.NonlinearSchurElimination`. Reflected implementation `komorebi_math.nonlinear.elimination.NonlinearSchurElimination`. The same runtime object is also available through `komorebi_math.NonlinearSchurElimination`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SCHUR-ELIMINATION`.

Manifest signature (s).

```
(retained_provider: 'DerivativeProvider', hidden_provider: 'DerivativeProvider', retained_dimension: 'int',
   ↪  hidden_dimension: 'int', base_retained: 'Any', base_hidden: 'Any', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. First and second derivatives after eliminating hidden variables.

Contract (D, C, H, R, X). Nonlinear Schur elimination requires retained and hidden derivative providers with a declared split of visible and hidden coordinates. The hidden derivative at the base point must be square and numerically invertible. Hidden solves require an initial point, a finite iteration limit, and a positive tolerance. Principal public operations and properties are `first_derivatives`, `second_derivative`, `solve_hidden`, `reduced_value`.

Guarantees (E, P, B, K). The first derivative contract implements the finite implicit derivative and reduced Schur derivative. The second derivative contract applies the declared provider derivatives through order two. Exact symbolic inputs may retain exact matrices. Numerical inputs receive residual certificates tied to the selected solve and base point. These are local finite statements, not global existence claims. The provenance registry records `PSC-III-T41` as Finite nonlinear Schur elimination. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · `ObstructionResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ObstructionResult`. Reflected implementation `komorebi_math.nonlinear.obstruction.ObstructionResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-OBSTRUCTION`.

Manifest signature (s).

```
(vanishes: 'bool', obstruction_coordinates: 'tuple[Any, ...]', cokernel_dimension: 'int', correction: 'Any |
    ↪ None', kernel_basis: 'tuple[Any, ...]', residual: 'float', certificate: 'Certificate') -> None
```

Definition. Computed obstruction coordinates and correction space.

Contract (D, C, H, R, X). A linear obstruction problem requires a finite matrix and a target residual of matching dimension. The obstruction square additionally requires compatible maps whose two routes can be compared. Tolerances must be positive and finite when numerical rank decisions are used. Principal public operations and properties are `require_correction`.

Guarantees (E, P, B, K). The solver separates the residual into a least squares range component and a cokernel obstruction component. The correction is accepted only when the obstruction norm is within tolerance. Certificates record residuals and rank information for the supplied finite matrix. They do not establish exact vanishing outside the represented arithmetic and tolerance model.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_obstruction.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `ObstructionSquare`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ObstructionSquare`. Reflected implementation `komorebi_math.nonlinear.obstruction.ObstructionSquare`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-OBSTRUCTION`.

Manifest signature (s).

```
(source_correction: 'Any', target_correction: 'Any', source_map: 'Any', target_map: 'Any', backend: 'str |
    ↪ LinearAlgebraBackend | None' = None, tolerance: 'float' = 1e-10) -> None
```

Definition. A commuting square inducing a map between cokernels.

Contract (D, C, H, R, X). A linear obstruction problem requires a finite matrix and a target residual of matching dimension. The obstruction square additionally requires compatible maps whose two routes can be compared. Tolerances must be positive and finite when numerical rank decisions are used. Principal public operations and properties are `certificate`, `transport_defect`.

Guarantees (E, P, B, K). The solver separates the residual into a least squares range component and a cokernel obstruction component. The correction is accepted only when the obstruction norm is within tolerance. Certificates record residuals and rank information for the supplied finite matrix. They do not establish exact vanishing outside the represented arithmetic and tolerance model.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_obstruction.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · PacketDerivativeResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketDerivativeResult`. Reflected implementation `komorebi_math.nonlinear.transport.PacketDerivativeResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SMOOTH-TRANSPORT`.

Manifest signature (s).

```
(time: 'float', step: 'float', maximum_derivative_residual: 'float', tangent_residual: 'float',
   ↪ partition_derivative_residual: 'float', certificate: 'Certificate') -> None
```

Definition. Finite-difference validation of declared moving-packet derivatives.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_transport.py` and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 40 and 44.

C.5A · Partition

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.Partition`. Reflected implementation `builtins.tuple`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `tuple`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Immutable nested tuple type used to encode a set partition of labeled direction positions.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the com-

posed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · PolynomialDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PolynomialDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.PolynomialDerivativeProvider`. The same runtime object is also available through `komorebi_math.PolynomialDerivativeProvider`, `komorebi_math.beta.PolynomialDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-DERIVATIVES`.

Manifest signature (s).

```
(tensors: 'Mapping[int, Any]', *, source_dimension: 'int | None' = None, target_dimension: 'int | None' = None,
    ↪ exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance: 'float' = 1e-10, name: 'str' =
    ↪ 'polynomial derivative provider') -> 'None'
```

Definition. A finite polynomial map represented by symmetric coefficient tensors.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `degree`, `supports_order`, `value`, `derivative`, `symmetry_certificate`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-D04` as Symmetric polynomial derivative tensors. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 37 and 38.

C.5A · PolynomialLiftProblem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PolynomialLiftProblem`. Reflected implementation `komorebi_math.nonlinear.lifting.PolynomialLiftProblem`. The same runtime object is also available through `komorebi_math.PolynomialLiftProblem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(function: 'Callable[[tuple[int, ...]], Iterable[int]]', jacobian: 'Callable[[tuple[int, ...]], Any]', point:
   ↪ 'Any', *, prime: 'int', depth: 'int') -> 'None'
```

Definition. Lift a polynomial system by its Jacobian over the residual field.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `step`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `ProjectiveLimitRecord`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ProjectiveLimitRecord`. Reflected implementation `komorebi_math.nonlinear.filtered.ProjectiveLimitRecord`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(verified_prefix_depth: 'int', separated: 'bool', complete: 'bool', continuous: 'bool',
   ↪ compatible_infinite_branch: 'bool', conclusion: 'str') -> None
```

Definition. Declared hypotheses and conclusion for a conditional projective-limit step.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · `RightInverseCorrectionProblem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.RightInverseCorrectionProblem`. Reflected implementation `komorebi_math.nonlinear.correction.RightInverseCorrectionProblem`. The same runtime object is also available through `komorebi_math.RightInverseCorrectionProblem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (s).

```
(linear_map: 'Any', right_inverse: 'Any', nonlinear: 'Callable[[np.ndarray], Any]', target: 'Any', *, radius:
   ↪  'float', lipschitz_bound: 'float', tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Solve `D x + N(x) = y` by the theorem's fixed-point map.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point. Principal public operations and properties are `hypothesis_certificate`, `solve`, `target_stability_bound`.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions. The provenance registry records `PSC-III-T32` as Right-inverse nonlinear correction. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · `RightInverseCorrectionResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.RightInverseCorrectionResult`. Reflected implementation `komorebi_math.nonlinear.correction.RightInverseCorrectionResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-CORRECTION`.

Manifest signature (s).

```
(solution: 'np.ndarray', iterations: 'int', contraction_factor: 'float', equation_residual: 'float',
   ↪  fixed_point_residual: 'float', certificate: 'Certificate') -> None
```

Definition. Result of a finite right-inverse contraction correction.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · SchurDerivativeResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SchurDerivativeResult`. Reflected implementation `komorebi_math.nonlinear.elimination.SchurDerivativeResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SCHUR-ELIMINATION`.

Manifest signature (s).

```
(hidden_jacobian: 'Any', hidden_inverse: 'Any', implicit_derivative: 'Any', reduced_derivative: 'Any',
   ↪ certificate: 'Certificate') -> None
```

Definition. First-order implicit and reduced derivatives for nonlinear Schur elimination.

Contract (D, C, H, R, X). Nonlinear Schur elimination requires retained and hidden derivative providers with a declared split of visible and hidden coordinates. The hidden derivative at the base point must be square and numerically invertible. Hidden solves require an initial point, a finite iteration limit, and a positive tolerance.

Guarantees (E, P, B, K). The first derivative contract implements the finite implicit derivative and reduced Schur derivative. The second derivative contract applies the declared provider derivatives through order two. Exact symbolic inputs may retain exact matrices. Numerical inputs receive residual certificates tied to the selected solve and base point. These are local finite statements, not global existence claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · SchurSecondDerivativeResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SchurSecondDerivativeResult`. Reflected implementation `komorebi_math.nonlinear.elimination.SchurSecondDerivativeResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SCHUR-ELIMINATION`.

Manifest signature (s).

```
(lifted_left: 'Any', lifted_right: 'Any', implicit_second_derivative: 'Any', reduced_second_derivative: 'Any',
   ↪ certificate: 'Certificate') -> None
```

Definition. Second-order implicit and reduced derivatives for nonlinear Schur elimination.

Contract (D, C, H, R, X). Nonlinear Schur elimination requires retained and hidden derivative providers with a declared split of visible and hidden coordinates. The hidden derivative at the base point must be square and numerically invertible. Hidden solves require an initial point, a finite iteration limit, and a positive tolerance.

Guarantees (E, P, B, K). The first derivative contract implements the finite implicit derivative and reduced Schur derivative. The second derivative contract applies the declared provider derivatives through order two. Exact symbolic inputs may retain exact matrices. Numerical inputs receive residual certificates tied to the selected solve and base point. These are local finite statements, not global existence claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 41.

C.5A · SpectralSequenceEntry

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SpectralSequenceEntry`. Reflected implementation `komorebi_math.nonlinear.filtered.SpectralSequenceEntry`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(page: 'int', filtration_degree: 'int', complementary_degree: 'int', total_degree: 'int', dimension: 'int',
   ↪ outgoing_rank: 'int', incoming_rank: 'int') -> None
```

Definition. One bidegree entry on a finite filtered spectral-sequence page.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · SpectralSequencePage

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SpectralSequencePage`. Reflected implementation `komorebi_math.nonlinear.filtered.SpectralSequencePage`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(page: 'int', entries: 'tuple[SpectralSequenceEntry, ...]', total_dimension: 'int', total_differential_rank:
   ↪ 'int', certificate: 'Certificate') -> None
```

Definition. One exact finite page with entry and differential-rank data.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `entry`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · SympyDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SympyDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.SympyDerivativeProvider`. The same runtime object is also available through `komorebi_math.SympyDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-DERIVATIVES`.

Manifest signature (s).

```
(expressions: 'Sequence[Any]', variables: 'Sequence[Any]', *, name: 'str' = 'SymPy derivative provider') -> 'None'
```

Definition. Exact directional derivatives of a finite SymPy expression vector.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `supports_order`, `value`, `derivative`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-E05` as Exact symbolic directional derivatives. Its recorded status is `finite certificate`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 37 and 38.

C.5A · TorchDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.TorchDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.autodiff.TorchDerivativeProvider`. The same runtime object is also available through `komorebi_math.TorchDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-AUTODIFF`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', max_order: 'int' = 4, dtype:
    ↪ 'str' = 'float64', device: 'str | None' = None, name: 'str' = 'PyTorch derivative provider', exactness:
    ↪ 'Exactness' = <Exactness.NUMERICAL: 'numerical'>) -> None
```

Definition. Nested `torch.func.jvp` derivatives with lazy framework import.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process. Principal public operations and properties are `available`, `value`, `derivative`, `to_dict`.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls. The provenance registry records `PSC-III-N04T` as Lazy PyTorch derivative adapter. Its recorded status is

`finite certificate`. The provenance record notes that device and precision behavior are controlled by the external PyTorch runtime.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 37.

C.5A · `TransportEdge`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.TransportEdge`. Reflected implementation `komorebi_math.nonlinear.holonomy.TransportEdge`. The same runtime object is also available through `komorebi_math.TransportEdge`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-HOLONOMY`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Any', name: 'str' = '') -> None
```

Definition. An invertible transport from `source` to `target`.

Contract (D, C, H, R, X). A transport graph requires a finite vertex set and directed edges carrying compatible square matrices. Path transport requires composable endpoints. Gluing and intertwining checks require a chosen root and finite tolerance. Fundamental holonomy is computed from the selected spanning structure and recorded edges outside the tree. Principal public operations and properties are `reversed_name`.

Guarantees (E, P, B, K). The graph routines compute exact path products for exact input matrices or numerical products otherwise. Certificates compare finite cycle transports, root gauges, and intertwining residuals. The result describes the supplied finite graph. It is not a continuum connection or topological classification without additional hypotheses.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_holonomy.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `TransportGraph`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.TransportGraph`. Reflected implementation `komorebi_math.nonlinear.holonomy.TransportGraph`. The same runtime object is also available through `komorebi_math.TransportGraph`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-HOLONOMY`.

Manifest signature (s).

```
(vertices: 'Iterable[str]', edges: 'Iterable[TransportEdge]', *, backend: 'str | LinearAlgebraBackend | None' =
    ↪ None, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. A connected finite graph with invertible matrix transports.

Contract (D, C, H, R, X). A transport graph requires a finite vertex set and directed edges carrying compatible square matrices. Path transport requires composable endpoints. Gluing and intertwining checks require a chosen root and finite tolerance. Fundamental holonomy is computed from the selected spanning structure and recorded edges outside the tree. Principal public operations and properties are `edge_label`, `oriented_matrix`, `spanning_tree`, `tree_transports`, `tree_gauge`, `gauge_transform`, `fundamental_holonomies`, `gluing_certificate`, `intertwine`.

Guarantees (E, P, B, K). The graph routines compute exact path products for exact input matrices or numerical products otherwise. Certificates compare finite cycle transports, root gauges, and intertwining residuals. The result describes the supplied finite graph. It is not a continuum connection or topological classification without additional

hypotheses. The provenance registry records `PSC-III-D38` as Finite matrix transport system. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_holonomy.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · `TransportRefinementResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.TransportRefinementResult`. Reflected implementation `komorebi_math.nonlinear.transport.TransportRefinementResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SMOOTH-TRANSPORT`.

Manifest signature (s).

```
(coarse_steps: 'int', fine_steps: 'int', coarse: 'np.ndarray', fine: 'np.ndarray', difference: 'float',
   ↪ endpoint_intertwining: 'float', certificate: 'Certificate') -> None
```

Definition. A posteriori comparison of two midpoint transport resolutions.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_transport.py` and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 40 and 44.

C.5A · `autodiff_provider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.autodiff_provider`. Reflected implementation `komorebi_math.nonlinear.autodiff.autodiff_provider`. The same runtime object is also available through `komorebi_math.autodiff_provider`. Within `komorebi_math.nonlinear`, `automatic_derivative_provider` resolves to the same runtime object. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-AUTODIFF`.

Manifest signature (s).

```
(framework: 'str', function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', *,
   ↪ max_order: 'int' = 4, **options: 'Any') -> 'JaxDerivativeProvider | TorchDerivativeProvider'
```

Definition. Construct one supported external automatic-differentiation adapter.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. C.5A · `available_ad_frameworks`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.available_ad_frameworks`. Reflected implementation `komorebi_math.nonlinear.autodiff.available_ad_frameworks`. The same runtime object is also available through `komorebi_math.available_ad_frameworks`. Within `komorebi_math.nonlinear`, `available_autodiff_backends` resolves to the same runtime object. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-AUTODIFF`.

Manifest signature (`s`).

```
() -> 'dict[str, bool]'
```

Definition. Report usable optional AD frameworks without importing them in-process.

Contract (`D, C, H, R, X`). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (`E, P, B, K`). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 37.

C.5A · `available_autodiff_backends`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.available_autodiff_backends`. Reflected implementation `komorebi_math.nonlinear.autodiff.available_ad_frameworks`. The same runtime object is also available through `komorebi_math.available_autodiff_backends`. Within `komorebi_math.nonlinear`, `available_ad_frameworks` resolves to the same runtime object. The public export name maps to implementation object `available_ad_frameworks`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-AUTODIFF`.

Manifest signature (`s`).

```
() -> 'dict[str, bool]'
```

Definition. Report usable optional AD frameworks without importing them in-process.

Contract (`D, C, H, R, X`). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (`E, P, B, K`). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 37.

C.5A · build_lift_tree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.build_lift_tree`. Reflected implementation `komorebi_math.nonlinear.lifting.build_lift_tree`. The same runtime object is also available through `komorebi_math.build_lift_tree`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(problem_factory: 'Callable[[tuple[int, ...], int], LinearLiftProblem | PolynomialLiftProblem]', roots:
   ↪ 'Iterable[tuple[int, ...]]', *, prime: 'int', start_depth: 'int', max_depth: 'int', max_nodes: 'int' =
   ↪ 100000) -> 'FiniteLiftTree'
```

Definition. Build a finite lift tree from exact one step correction problems.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit. The provenance registry records `PSC-III-T30` as Finite lift tree construction. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · conditional_projective_limit_completion

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.conditional_projective_limit_completion`. Reflected implementation `komorebi_math.nonlinear.filtered.conditional_projective_limit_completion`. The same runtime object is also available through `komorebi_math.conditional_projective_limit_completion`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(verified_prefix_depth: 'int', *, separated: 'bool', complete: 'bool', continuous: 'bool',
   ↪ compatible_infinite_branch: 'bool') -> 'ConditionalResult[ProjectiveLimitRecord]'
```

Definition. Record the conditional infinite filtered-lifting conclusion.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

C.5A · direct_packet_rotation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.direct_packet_rotation`. Reflected implementation `komorebi_math.nonlinear.transport.direct_packet_rotation`. The same runtime object is also available through `komorebi_math.direct_packet_rotation`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-SMOOTH-TRANSPORT`.

Manifest signature (s).

```
(source: 'Iterable[Any]', target: 'Iterable[Any]', *, tolerance: 'float' = 1e-10) -> 'DirectRotationResult'
```

Definition. Return the polar unitary of `sum target[a] source[a]`.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates. The provenance registry records `PSC-III-T55` as Direct rotation of finite packet systems. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_transport.py` and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 40 and 44.

C.5A · divided_square_packets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.divided_square_packets`. Reflected implementation `komorebi_math.nonlinear.graded.divided_square_packets`. The same runtime object is also available through `komorebi_math.divided_square_packets`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-GRADED`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', components: 'Mapping[str, Any]', differential: 'LinearOperation', bracket:
    ↪ 'BracketOperation', divided_square: 'LinearOperation', *, exactness: 'Exactness' = <Exactness.NUMERICAL:
    ↪ 'numerical'>, tolerance: 'float' = 1e-10) -> 'DividedSquareResult'
```

Definition. Assemble `d eta + q(eta)` from divided-square packet identities.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this con-

tract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · faa_di_bruno

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.faa_di_bruno`. Reflected implementation `komorebi_math.nonlinear.composition.faa_di_bruno`. The same runtime object is also available through `komorebi_math.faa_di_bruno`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(outer: 'DerivativeProvider', inner: 'DerivativeProvider', point: 'Any', directions: 'Sequence[Any]', *,
    ↪ direct_provider: 'DerivativeProvider | None' = None, tolerance: 'float' = 1e-09, retain_terms: 'bool' =
    ↪ True) -> 'FaaDiBrunoResult'
```

Definition. Evaluate the directional higher chain rule for `outer(inner(x))`.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded. The provenance registry records `PSC-III-T10` as Finite dimensional Faà di Bruno formula. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · higher_maurer_cartan_packets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.higher_maurer_cartan_packets`. Reflected implementation `komorebi_math.nonlinear.graded.higher_maurer_cartan_packets`. The same runtime object is also available through `komorebi_math.higher_maurer_cartan_packets`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-GRADED`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', components: 'Mapping[str, Any]', operations: 'Mapping[int,
    ↪ GradedOperationCallable]', *, exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance:
    ↪ 'float' = 1e-10) -> 'HigherMaurerCartanResult'
```

Definition. Assemble a finite truncation `sum_r ell_r(eta^r)/r!` by labels.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred. The provenance registry records `PSC-III-P20` as Finite truncated packet equations

for higher operations. Its recorded status is `proved`. The provenance record notes that the result does not certify convergence of an infinite Maurer–Cartan series.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · `labeled_composition_term_count`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.labeled_composition_term_count`. Reflected implementation `komorebi_math.nonlinear.composition.labeled_composition_term_count`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(order: 'int', intermediate_packets: 'int') -> 'int'
```

Definition. Return `sum_k S(order,k) * intermediate_packets**k`.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · `maurer_cartan_packets`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.maurer_cartan_packets`. Reflected implementation `komorebi_math.nonlinear.graded.maurer_cartan_packets`. The same runtime object is also available through `komorebi_math.maurer_cartan_packets`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-GRADED`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', components: 'Mapping[str, Any]', differential: 'LinearOperation', bracket:
    ↪ 'BracketOperation', *, exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance: 'float' =
    ↪ 1e-10) -> 'MaurerCartanResult'
```

Definition. Assemble the finite packet equations for `d eta + [eta,eta]/2`.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred. The provenance registry records `PSC-III-T19` as Packet Maurer–Cartan equations. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5A · `packet_faa_di_bruno`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.packet_faa_di_bruno`. Reflected implementation `komorebi_math.nonlinear.composition.packet_faa_di_bruno`. The same runtime object is also available through `komorebi_math.packet_faa_di_bruno`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(outer: 'DerivativeProvider', inner: 'DerivativeProvider', point: 'Any', directions: 'Sequence[Any]', source:
    ↪ 'PacketSystem', intermediate: 'PacketSystem', target: 'PacketSystem', *, input_packets:
    ↪ 'Sequence[PacketLabel]', output_packet: 'PacketLabel', inner_support: 'Mapping[int, PacketJetSupport] |
    ↪ None' = None, outer_support: 'Mapping[int, PacketJetSupport] | None' = None, tolerance: 'float | None' =
    ↪ None, retain_terms: 'bool' = True, max_terms: 'int' = 1000000) -> 'FaaDiBrunoResult'
```

Definition. Evaluate one packet jet of a composition through decorated partitions.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded. The provenance registry records `PSC-III-T11A` as Packet Faà di Bruno formula. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · `set_partitions`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.set_partitions`. Reflected implementation `komorebi_math.nonlinear.composition.set_partitions`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(order: 'int') -> 'tuple[Partition, ...]'
```

Definition. Public finite nonlinear contract reflected from the implementation.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · solve_mod_prime

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.solve_mod_prime`. Reflected implementation `komorebi_math.nonlinear.lifting.solve_mod_prime`. The same runtime object is also available through `komorebi_math.solve_mod_prime`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-LIFTING`.

Manifest signature (s).

```
(matrix: 'Any', rhs: 'Any', prime: 'int') -> 'ModularLinearSolution'
```

Definition. Solve a finite linear system modulo a prime by exact row reduction.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit. The provenance registry records `PSC-III-LIN-FP` as Linear correction space over a prime field. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 40.

C.5A · status

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.status`. Reflected implementation `komorebi_math.nonlinear.status`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-NAMESPACE`.

Manifest signature (s).

```
() -> komorebi_math.registry.FeatureSpec
```

Definition. Return the feature registry record for this package component.

Contract (D, C, H, R, X). The namespace status route takes no arguments and returns the registered nonlinear feature record for the installed package. It reports implementation availability and package metadata. It does not probe optional automatic differentiation or GPU runtimes.

Guarantees (E, P, B, K). The result is deterministic for one installed source tree. The route performs a registry lookup with constant auxiliary storage. It is an availability record, not a theorem certificate or backend qualification result.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_certificates_registry.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 6.

C.5A · `stirling_second`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.stirling_second`. Reflected implementation `komorebi_math.nonlinear.composition.stirling_second`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-COMPOSITION`.

Manifest signature (s).

```
(order: 'int', blocks: 'int') -> 'int'
```

Definition. Return an exact Stirling number of the second kind.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5A · `verify_finite_filtered_branch`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.verify_finite_filtered_branch`. Reflected implementation `komorebi_math.nonlinear.filtered.verify_finite_filtered_branch`. The same runtime object is also available through `komorebi_math.verify_finite_filtered_branch`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-FILTERED`.

Manifest signature (s).

```
(source: 'FilteredVectorSpace', target: 'FilteredVectorSpace', map_function: 'Callable[[tuple[int, ...]],
   ↪ Sequence[int]]', approximations: 'Sequence[Sequence[int]]', *, start_depth: 'int' = 0) ->
   ↪ 'FiniteFilteredBranchResult'
```

Definition. Verify a compatible branch through a finite terminal filtration.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear calculus foundations exercises representative finite identities, rejection paths, implementation ownership, and alias behavior for this contract family. The source validator for nonlinear calculus foundations checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 42.

Nonlinear foundations reference. The 80 cards in C.5A cover 60 classes, 17 functions, and 3 data exports. Their recorded audit checks manifest and runtime identities, focused tests, independent finite checks, and reference anchors.

C.5B Packet jets, execution, streaming, and rooted trees: 69 entries

This section documents the public nonlinear namespace. It covers packet-jet addresses, families, support and Taylor reconstruction, sparse symmetric tensors, projection-cached execution, finite snapshots, resumable streams, optional GPU boundaries, observational profiling, and ordered rooted-tree expansions.

Contract family	Cards
Packet jets, supports, and Taylor reconstruction	8
Sparse symmetric tensors	3
Projection-cached and optional CuPy execution	12
Portable packet-jet snapshots	3
Resumable chunked streams and schemas	14
Persisted-snapshot GPU validation	6
Complexity estimates and observational profiles	7
Ordered rooted trees and fixed-point expansions	14
Namespace availability records	2
Total	**69**

The boundary remains finite and explicit. Packet support is certified only over the tested packet bases. Snapshots and streams preserve one captured finite multilinear block. Timing records describe one local environment. GPU contracts require actual CuPy and CUDA availability before device execution can be qualified. Rooted-tree convergence remains conditional on the supplied scalar majorant and contraction inequalities.

C.5B · CuPyDeviceDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.CuPyDeviceDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.execution.CupyDeviceDerivativeProvider`. The same runtime object is also available through `komorebi_math.CuPyDeviceDerivativeProvider`. The public export name maps to implementation object `CupyDeviceDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Optional protocol consumed by `CupyPacketJetExecutor`.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `supports_order`, `device_derivative`.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · CuPyPacketJetExecutor

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.CuPyPacketJetExecutor`. Reflected implementation `komorebi_math.nonlinear.execution.CupyPacketJetExecutor`. The same runtime object is also available through `komorebi_math.CuPyPacketJetExecutor`. The public export name maps to implementation object `CupyPacketJetExecutor`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', plan: 'PacketJetExecutionPlan | None' = None) -> 'None'
```

Definition. Device-resident packet projections and polynomial jet reconstruction.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `execute`, `synchronize`, `hardware_certificate`.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `CuPyPacketJetSnapshotExecutor`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.CuPyPacketJetSnapshotExecutor`. Reflected implementation `komorebi_math.nonlinear.gpu.CuPySnapshotExecutor`. The same runtime object is also available through `komorebi_math.CuPyPacketJetSnapshotExecutor`. Within `komorebi_math.nonlinear`, `CuPySnapshotExecutor` resolves to the same runtime object. The public export name maps to implementation object `CuPySnapshotExecutor`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GPU`.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', *, dtype: 'Any | None' = None) -> 'None'
```

Definition. Device evaluator for one sparse `PacketJetSnapshot`.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance. Principal public operations and properties are `evaluate_batch`, `evaluate`.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified. The provenance registry records `PSC-III-N59` as Sparse CuPy packet-jet execution. Its recorded status is `finite certificate`. Recorded limitation: no performance claim without matched hardware benchmarking.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43. The recorded audit runtime had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.5B · `CuPyPolynomialDerivativeProvider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.CuPyPolynomialDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.execution.CupyPolynomialDerivativeProvider`. The same runtime object is also available through `komorebi_math.CuPyPolynomialDerivativeProvider`. The public export name maps to implementation object `CupyPolynomialDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(tensors: 'Mapping[int, Any]', *, source_dimension: 'int | None' = None, target_dimension: 'int | None' = None,
    ↪ tolerance: 'float' = 1e-10, name: 'str' = 'CuPy polynomial derivative provider') -> 'None'
```

Definition. Dense polynomial derivatives resident on one CuPy device.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address

budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `degree`, `supports_order`, `device_value`, `value`, `device_derivative`, `derivative`, `synchronize`.

Guarantees (`E`, `P`, `B`, `K`). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `CuPyRuntimeStatus`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.nonlinear.CuPyRuntimeStatus`. Reflected implementation `komorebi_math.nonlinear.gpu.CuPyRuntimeStatus`. The same runtime object is also available through `komorebi_math.CuPyRuntimeStatus`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GPU`.

Manifest signature (`s`).

```
(installed: 'bool', runtime_available: 'bool', device_count: 'int', runtime_version: 'int | None', error: 'str |
    ↪ None' = None) -> None
```

Definition. Observed CuPy import and CUDA device state.

Contract (`D`, `C`, `H`, `R`, `X`). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (`E`, `P`, `B`, `K`). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43. The recorded audit runtime had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.5B · `CuPySnapshotExecutor`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.nonlinear.CuPySnapshotExecutor`. Reflected implementation `komorebi_math.nonlinear.gpu.CuPySnapshotExecutor`. The same runtime object is also available through `komorebi_math.CuPySnapshotExecutor`. Within `komorebi_math.nonlinear`, `CuPyPacketJetSnapshotExecutor` resolves to the same runtime object. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GPU`.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', *, dtype: 'Any | None' = None) -> 'None'
```

Definition. Device evaluator for one sparse `PacketJetSnapshot`.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance. Principal public operations and properties are `evaluate_batch`, `evaluate`.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified. The provenance registry records `PSC-III-N59` as Sparse CuPy packet-jet execution. Its recorded status is `finite certificate`. Recorded limitation: no performance claim without matched hardware benchmarking.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43. The recorded audit runtime had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.5B · `CuPyValidationResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.CuPyValidationResult`. Reflected implementation `komorebi_math.nonlinear.gpu.CuPyValidationResult`. The same runtime object is also available through `komorebi_math.CuPyValidationResult`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-GPU`.

Manifest signature (s).

```
(probe_count: 'int', maximum_residual: 'float', runtime: 'CuPyRuntimeStatus', certificate: 'Certificate') -> None
```

Definition. Matched CPU and CuPy packet-jet validation data.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43. The recorded audit runtime had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.5B · FEATURE_KEY

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.FEATURE_KEY`. Reflected implementation `builtins.str`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `str`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-NAMESPACE`.

Manifest signature (s).

```
null
```

Definition. Literal registry key for the nonlinear package component.

Contract (D, C, H, R, X). The namespace marker is the literal feature key used by the registry. The `require` route takes no arguments and returns successfully for this implemented package component. Neither contract imports optional GPU runtimes or changes global state.

Guarantees (E, P, B, K). The feature key is deterministic for the installed source tree. The availability check has constant auxiliary storage and makes no statement about optional devices, performance, or the validity of a particular nonlinear model.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_certificates_registry.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 6.

C.5B · MajorantConvergence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.MajorantConvergence`. Reflected implementation `komorebi_math.nonlinear.trees.MajorantConvergence`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(seed_norm: 'float', operation_norms: 'dict[int, float]', radius: 'float', image_bound: 'float', contraction:
    ↪  'float', certificate: 'Certificate') -> None
```

Definition. Scalar majorant data for a polynomial fixed-point problem.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius. Principal public operations and properties are `scalar_map`, `scalar_iterates`, `picard_tail_bound`.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · MultilinearOperation

Identity (q, a, t, k). Public research-manifest route komorebi_math.nonlinear.MultilinearOperation. Reflected implementation collections.abc.Callable. The same runtime object is also available through komorebi_math.MultilinearOperation. The public export name maps to implementation object Callable. The komorebi_math.nonlinear route is governed by [RESEARCH] policy pre-beta-additive. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind data. Profile C5-ROOTED-TREES.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Callable type alias for one finite multilinear operation on a tuple of values.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_nonlinear_trees.py. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · OrderedRootedTree

Identity (q, a, t, k). Public research-manifest route komorebi_math.nonlinear.OrderedRootedTree. Reflected implementation komorebi_math.nonlinear.trees.OrderedRootedTree. The same runtime object is also available through komorebi_math.OrderedRootedTree. The komorebi_math.nonlinear route is governed by [RESEARCH] policy pre-beta-additive. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind class. Profile C5-ROOTED-TREES.

Manifest signature (s).

```
(children: "tuple['OrderedRootedTree', ...]" = ()) -> None
```

Definition. An unlabeled ordered rooted tree.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius. Principal public operations and properties are leaf, is_leaf, arity, height, leaf_count, internal_count, vertex_count, arity_profile, prefix, to_dict.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records PSC-III-D13 as Finite ordered rooted tree. Its recorded status is definition.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_nonlinear_trees.py. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity

for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · PACKET_JET_CHUNK_SCHEMA

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PACKET_JET_CHUNK_SCHEMA`. Reflected implementation `builtins.str`. The same runtime object is also available through `komorebi_math.PACKET_JET_CHUNK_SCHEMA`, `komorebi_math.beta.PACKET_JET_CHUNK_SCHEMA`. The public export name maps to implementation object `str`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-STREAMING`.

Manifest signature (s).

```
null
```

Definition. Canonical schema identifier for one packet-jet coefficient chunk envelope.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PACKET_JET_CHUNK_SCHEMA_VERSION

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PACKET_JET_CHUNK_SCHEMA_VERSION`. Reflected implementation `builtins.int`. The same runtime object is also available through `komorebi_math.PACKET_JET_CHUNK_SCHEMA_VERSION`, `komorebi_math.beta.PACKET_JET_CHUNK_SCHEMA_VERSION`. Within `komorebi_math.nonlinear`, `PACKET_JET_STREAM_SCHEMA_VERSION` resolves to the same runtime object. The public export name maps to implementation object `int`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-STREAMING`.

Manifest signature (s).

```
null
```

Definition. Current integer version of the packet-jet chunk schema.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PACKET_JET_STREAM_SCHEMA

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PACKET_JET_STREAM_SCHEMA`. Reflected implementation `builtins.str`. The same runtime object is also available through `komorebi_math.PACKET_JET_STREAM_SCHEMA`, `komorebi_math.beta.PACKET_JET_STREAM_SCHEMA`. The public export name maps to implementation object `str`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-STREAMING`.

Manifest signature (s).

```
null
```

Definition. Canonical schema identifier for a packet-jet stream manifest envelope.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PACKET_JET_STREAM_SCHEMA_VERSION

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PACKET_JET_STREAM_SCHEMA_VERSION`. Reflected implementation `builtins.int`. The same runtime object is also available through `komorebi_math.PACKET_JET_STREAM_SCHEMA_VERSION`, `komorebi_math.beta.PACKET_JET_STREAM_SCHEMA_VERSION`. Within `komorebi_math.nonlinear`, `PACKET_JET_CHUNK_SCHEMA_VERSION` resolves to the same runtime object. The public export name maps to implementation object `int`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-STREAMING`.

Manifest signature (s).

```
null
```

Definition. Current integer version of the packet-jet stream manifest schema.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured

chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PacketJet

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJet`. Reflected implementation `komorebi_math.nonlinear.jets.PacketJet`. The same runtime object is also available through `komorebi_math.PacketJet`, `komorebi_math.beta.PacketJet`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', point: 'Any', source: 'PacketSystem', target: 'PacketSystem', output_index:
    ↪ 'int', input_indices: 'tuple[int, ...]') -> None
```

Definition. One projected multilinear derivative block.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets. Principal public operations and properties are `order`, `address`, `exactness`, `evaluate`, `norm_bound`, `symmetry_certificate`, `to_dict`.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-D06` as Finite packet jet. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · PacketJetAddress

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetAddress`. Reflected implementation `komorebi_math.nonlinear.jets.PacketJetAddress`. The same runtime object is also available through `komorebi_math.beta.PacketJetAddress`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
(output: 'str', inputs: 'tuple[str, ...]') -> None
```

Definition. The output and ordered input packet addresses of one jet block.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets. Principal public operations and properties are `order`, `to_dict`.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · `PacketJetBatchResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetBatchResult`. Reflected implementation `komorebi_math.nonlinear.execution.PacketJetBatchResult`. The same runtime object is also available through `komorebi_math.PacketJetBatchResult`, `komorebi_math.beta.PacketJetBatchResult`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(evaluations: 'tuple[PacketJetEvaluation, ...]', reconstructed: 'Any', direct: 'Any', derivative_calls: 'int',
    ↪ input_projections: 'int', output_projections: 'int', pruned_blocks: 'int', backend: 'str', returned_to_host:
    ↪ 'bool', certificate: 'Certificate') -> None
```

Definition. Result of one projection-cached packet-jet execution.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `as_mapping`, `value`, `to_dict`.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PacketJetCoefficient

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetCoefficient`. Reflected implementation `komorebi_math.nonlinear.snapshots.PacketJetCoefficient`. The same runtime object is also available through `komorebi_math.beta.PacketJetCoefficient`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SNAPSHOTS`.

Manifest signature (s).

```
(indices: 'tuple[int, ...]', value: 'tuple[Any, ...]') -> None
```

Definition. One standard-basis coefficient of a persisted packet jet.

Contract (D, C, H, R, X). A snapshot captures one fixed packet jet by evaluating the ambient standard-basis tuples through an explicit finite budget. The source and target dimensions, base point, address, provider name, exactness, and sparse coefficients are stored in the record. Snapshot evaluation requires direction vectors of the recorded source dimension.

Guarantees (E, P, B, K). The snapshot is provider-independent after capture and reconstructs the recorded multilinear block from its stored coefficients. Its comparison certificate checks matched evaluations against the source jet on supplied probes. Exact coefficients preserve exact arithmetic. Numerical coefficients use the stored tolerance and certificate. Dense capture cost grows as the source dimension raised to the jet order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 38 and 43.

C.5B · PacketJetComplexityEstimate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetComplexityEstimate`. Reflected implementation `komorebi_math.nonlinear.profiling.PacketJetComplexityEstimate`. The same runtime object is also available through `komorebi_math.PacketJetComplexityEstimate`, `komorebi_math.beta.PacketJetComplexityEstimate`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PROFILING`.

Manifest signature (s).

```
(order: 'int', source_dimension: 'int', target_dimension: 'int', source_packets: 'int', target_packets: 'int',
    ↪ family_addresses: 'int', active_addresses: 'int', pruned_addresses: 'int', input_groups: 'int',
    ↪ naive_derivative_calls: 'int', planned_derivative_calls: 'int', projected_input_vectors: 'int',
    ↪ output_projections: 'int', dense_basis_evaluations: 'int', dense_tensor_elements: 'int', certificate:
    ↪ 'Certificate') -> None
```

Definition. Exact finite counts implied by packet and ambient dimensions.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets. Principal public operations and properties are `derivative_call_reduction`, `to_dict`.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The

independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PacketJetEvaluation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetEvaluation`. Reflected implementation `komorebi_math.nonlinear.execution.PacketJetEvaluation`. The same runtime object is also available through `komorebi_math.beta.PacketJetEvaluation`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(address: 'PacketJetAddress', value: 'Any') -> None
```

Definition. One evaluated packet-jet address and its projected target value.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PacketJetExecutionPlan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetExecutionPlan`. Reflected implementation `komorebi_math.nonlinear.execution.PacketJetExecutionPlan`. The same runtime object is also available through `komorebi_math.PacketJetExecutionPlan`, `komorebi_math.beta.PacketJetExecutionPlan`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(order: 'int', source_names: 'tuple[str, ...]', target_names: 'tuple[str, ...]', groups:
    ↪ 'tuple[PacketJetInputGroup, ...]', active_addresses: 'tuple[PacketJetAddress, ...]', pruned_addresses:
    ↪ 'tuple[PacketJetAddress, ...]', support_was_supplied: 'bool', support_complete: 'bool', certificate:
    ↪ 'Certificate') -> None
```

Definition. A deterministic grouping of packet-jet blocks by projected inputs.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `active_address_count`, `pruned_address_count`, `full_address_count`, `derivative_call_count`, `naive_derivative_call_count`, `derivative_call_reduction`, `matches`, `to_dict`.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly. The provenance registry records `PSC-III-A10` as Projection-cached packet-jet execution plan. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetFamily`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetFamily`. Reflected implementation `komorebi_math.nonlinear.jets.PacketJetFamily`. The same runtime object is also available through `komorebi_math.PacketJetFamily`, `komorebi_math.beta.PacketJetFamily`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', point: 'Any', source: 'PacketSystem', target: 'PacketSystem', order: 'int') ->
    ↪ 'None'
```

Definition. Every packet block of one derivative order at one base point.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets. Principal public operations and properties are `jet`, `addresses`, `reconstruct`, `reconstruction_certificate`, `to_dict`.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-T07` as Exact reconstruction of finite packet derivatives. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · `PacketJetInputGroup`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetInputGroup`. Reflected implementation `komorebi_math.nonlinear.execution.PacketJetInputGroup`. The same runtime object is also available through `komorebi_math.beta.PacketJetInputGroup`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(inputs: 'tuple[int, ...]', outputs: 'tuple[int, ...]') -> None
```

Definition. Active output packets sharing one ordered input-packet address.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetProfileReport`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetProfileReport`. Reflected implementation `komorebi_math.nonlinear.profiling.PacketJetProfileReport`. The same runtime object is also available through `komorebi_math.PacketJetProfileReport`, `komorebi_math.beta.PacketJetProfileReport`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PROFILING`.

Manifest signature (s).

```
(estimate: 'PacketJetComplexityEstimate', stages: 'tuple[RuntimeStageProfile, ...]', environment: 'Mapping[str,
    ↪ Any]', certificate: 'Certificate') -> None
```

Definition. Exact counts paired with environment-specific runtime observations.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets. Principal public operations and properties are `to_dict`.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · PacketJetSnapshot

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetSnapshot`. Reflected implementation `komorebi_math.nonlinear.snapshots.PacketJetSnapshot`. The same runtime object is also available through `komorebi_math.PacketJetSnapshot`, `komorebi_math.beta.PacketJetSnapshot`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SNAPSHOTS`.

Manifest signature (s).

```
(address: 'PacketJetAddress', source_dimension: 'int', target_dimension: 'int', provider_name: 'str', exactness:
    ↪ 'Exactness', point: 'tuple[Any, ...]', coefficients: 'tuple[PacketJetCoefficient, ...]',
    ↪ capture_certificate: 'Certificate') -> None
```

Definition. A provider-independent sparse coefficient record of one packet jet.

Contract (D, C, H, R, X). A snapshot captures one fixed packet jet by evaluating the ambient standard-basis tuples through an explicit finite budget. The source and target dimensions, base point, address, provider name, exactness, and sparse coefficients are stored in the record. Snapshot evaluation requires direction vectors of the recorded source dimension. Principal public operations and properties are `order`, `nnz`, `dense_coefficient_count`, `coefficient`, `evaluate`, `to_dense`, `comparison_certificate`, `to_dict`.

Guarantees (E, P, B, K). The snapshot is provider-independent after capture and reconstructs the recorded multilinear block from its stored coefficients. Its comparison certificate checks matched evaluations against the source jet on supplied probes. Exact coefficients preserve exact arithmetic. Numerical coefficients use the stored tolerance and certificate. Dense capture cost grows as the source dimension raised to the jet order. The provenance registry records `PSC-III-D58` as Finite packet-jet snapshot. Its recorded status is `finite certificate`. Recorded limitation: snapshot represents one fixed order, address, and base point.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 38 and 43.

C.5B · PacketJetSnapshotStreamReader

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetSnapshotStreamReader`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetSnapshotStreamReader`. The same runtime object is also available through `komorebi_math.PacketJetSnapshotStreamReader`, `komorebi_math.beta.PacketJetSnapshotStreamReader`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(path: 'str | os.PathLike[str]', *, allow_incomplete: 'bool' = False, verify_chunks: 'bool' = False) -> 'None'
```

Definition. Bounded-memory reader for a complete or explicitly allowed partial stream.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed. Principal public operations and properties are `complete`, `iter_chunks`, `iter_coefficients`, `select`, `evaluate`, `load_snapshot`, `verify`.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetStreamChunkRecord`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetStreamChunkRecord`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamChunkRecord`. The same runtime object is also available through `komorebi_math.PacketJetStreamChunkRecord`, `komorebi_math.beta.PacketJetStreamChunkRecord`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(index: 'int', filename: 'str', basis_start: 'int', basis_stop: 'int', coefficient_start: 'int', coefficient_stop:
   ↪ 'int', payload_sha256: 'str', byte_count: 'int') -> None
```

Definition. One immutable chunk index entry in a packet-jet stream manifest.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed. Principal public operations and properties are `coefficient_count`, `basis_count`, `to_dict`, `from_dict`.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetStreamManifest`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetStreamManifest`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamManifest`. The same runtime object is also available through `komorebi_math.PacketJetStreamManifest`, `komorebi_math.beta.PacketJetStreamManifest`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(state: 'StreamState', producer_version: 'str', address: 'PacketJetAddress', source_dimension: 'int',
   ↪ target_dimension: 'int', provider_name: 'str', exactness: 'Exactness', point: 'tuple[Any, ...]', tolerance:
   ↪ 'float', dense_coefficient_count: 'int', capture_mode: 'CaptureMode', source_digest: 'str', metadata_sha256:

   ↪ maximum_omitted_basis_norm: 'float', chunks: 'tuple[PacketJetStreamChunkRecord, ...]', capture_certificate:
   ↪ 'Certificate | None', stream_sha256: 'str') -> None
```

Definition. Validated metadata and progress for one chunked packet-jet stream.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed. Principal public operations and properties are `complete`, `order`, `metadata_dict`, `to_payload`, `from_payload`.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetStreamSelection`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetStreamSelection`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamSelection`. The same runtime object is also available through `komorebi_math.PacketJetStreamSelection`, `komorebi_math.beta.PacketJetStreamSelection`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(coefficient_start: 'int', coefficient_stop: 'int', coefficients: 'tuple[PacketJetCoefficient, ...]',
   ↪  complete_snapshot: 'bool', certificate: 'Certificate') -> None
```

Definition. A bounded coefficient selection loaded from a packet-jet stream.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetStreamWriteResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketJetStreamWriteResult`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamWriteResult`. The same runtime object is also available through `komorebi_math.PacketJetStreamWriteResult`, `komorebi_math.beta.PacketJetStreamWriteResult`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-STREAMING`.

Manifest signature (`s`).

```
(destination: 'Path', active_path: 'Path', completed: 'bool', resumed: 'bool', chunks_written: 'int',
   ↪ evaluations_written: 'int', coefficients_written: 'int', manifest: 'PacketJetStreamManifest', certificate:
   ↪ 'Certificate') -> None
```

Definition. Progress returned by a direct or snapshot stream write.

Contract (`D, C, H, R, X`). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (`E, P, B, K`). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `PacketJetSupport`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.PacketJetSupport`. Reflected implementation `komorebi_math.nonlinear.jets.PacketJetSupport`. The same runtime object is also available through `komorebi_math.beta.PacketJetSupport`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PACKET-JETS`.

Manifest signature (`s`).

```
(order: 'int', nonzero: 'tuple[PacketJetAddress, ...]', zero: 'tuple[PacketJetAddress, ...]', untested:
   ↪ 'tuple[PacketJetAddress, ...]', evaluations: 'int', certificate: 'Certificate') -> None
```

Definition. Finite basis test for zero and nonzero packet derivative blocks.

Contract (`D, C, H, R, X`). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets. Principal public operations and properties are `complete`, `contains`.

Guarantees (`E, P, B, K`). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · PacketLabel

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketLabel`. Reflected implementation `types.UnionType`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The public export name maps to implementation object `UnionType`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
null
```

Definition. Public union type for packet indices or packet names.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · PacketTaylorResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketTaylorResult`. Reflected implementation `komorebi_math.nonlinear.jets.PacketTaylorResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
(approximation: 'Any', observed: 'Any', truncation_residual: 'float', order_certificates: 'tuple[Certificate,
   ↪  ...]', certificate: 'Certificate') -> None
```

Definition. A truncated Taylor value assembled from reconstructed packet jets.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation

ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · PacketTreeResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PacketTreeResult`. Reflected implementation `komorebi_math.nonlinear.trees.PacketTreeResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(value: 'Any', packet_values: 'tuple[Any, ...]', evaluated_blocks: 'int', pruned_blocks: 'int', certificate:
   ↪ 'Certificate') -> None
```

Definition. Packet-labeled rooted-tree evaluation with pruning statistics.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · PolynomialFixedPointProblem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.PolynomialFixedPointProblem`. Reflected implementation `komorebi_math.nonlinear.trees.PolynomialFixedPointProblem`. The same runtime object is also available through `komorebi_math.PolynomialFixedPointProblem`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(seed: 'Any', operations: 'Mapping[int, MultilinearOperation]', *, exactness: 'Exactness' = <Exactness.NUMERICAL:
   ↪ 'numerical'>, tolerance: 'float' = 1e-10, name: 'str' = 'polynomial fixed-point problem') -> 'None'
```

Definition. A finite-dimensional equation `u = s + sum_r B_r(u,...,u)`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius. Principal public operations and properties are `operation`, `map`, `residual`, `picard`, `tree_value`, `tree_expansion`, `convergence_certificate`.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow

exponentially or faster with height and arity. The provenance registry records `PSC-III-T14A` as Finite polynomial rooted-tree expansion. Its recorded status is `finite certificate`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · `RuntimeProfileSample`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.RuntimeProfileSample`. Reflected implementation `komorebi_math.nonlinear.profiling.RuntimeProfileSample`. The same runtime object is also available through `komorebi_math.RuntimeProfileSample`, `komorebi_math.beta.RuntimeProfileSample`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PROFILING`.

Manifest signature (`s`).

```
(duration_ns: 'int', traced_peak_bytes: 'int') -> None
```

Definition. One observed duration and Python allocation peak.

Contract (`D, C, H, R, X`). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (`E, P, B, K`). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `RuntimeStageProfile`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.RuntimeStageProfile`. Reflected implementation `komorebi_math.nonlinear.profiling.RuntimeStageProfile`. The same runtime object is also available through `komorebi_math.RuntimeStageProfile`, `komorebi_math.beta.RuntimeStageProfile`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-PROFILING`.

Manifest signature (`s`).

```
(name: 'str', scope: 'str', warmup: 'int', samples: 'tuple[RuntimeProfileSample, ...]') -> None
```

Definition. Repeated observations for one precisely named runtime stage.

Contract (`D, C, H, R, X`). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets. Principal public operations and properties are `repetitions`, `minimum_duration_ns`, `median_duration_ns`, `maximum_duration_ns`, `median_peak_bytes`, `maximum_peak_bytes`, `to_dict`.

Guarantees (`E, P, B, K`). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observa-

tions. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · SparsePolynomialDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SparsePolynomialDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.sparse.SparsePolynomialDerivativeProvider`. The same runtime object is also available through `komorebi_math.SparsePolynomialDerivativeProvider`, `komorebi_math.beta.SparsePolynomialDerivativeProvider`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SPARSE-TENSORS`.

Manifest signature (s).

```
(tensors: 'Mapping[int, SparseSymmetricTensor | Mapping[tuple[int, ...], Any] | Any]', *, source_dimension: 'int |
    ↪ None' = None, target_dimension: 'int | None' = None, exactness: 'Exactness' = <Exactness.NUMERICAL:
    ↪ 'numerical'>, tolerance: 'float' = 1e-10, name: 'str' = 'sparse polynomial derivative provider') -> 'None'
```

Definition. Polynomial derivatives evaluated from sparse symmetric tensor orbits.

Contract (D, C, H, R, X). Sparse tensor records require nonnegative output indices, canonical nondecreasing source-index tuples, positive finite dimensions, and coefficients compatible with the selected exactness model. A sparse polynomial provider requires one finite tensor per declared derivative order and common source and target dimensions. Principal public operations and properties are `from_dense_provider`, `degree`, `stored_entry_count`, `dense_entry_count`, `storage_ratio`, `supports_order`, `value`, `derivative`, `to_dense_provider`, `storage_certificate`, `to_dict`.

Guarantees (E, P, B, K). Orbit storage represents symmetric ordered tensor entries without storing every permutation. Contraction and dense reconstruction agree with the implemented orbit expansion. Exact object arithmetic remains exact when requested and supported. Numerical compression uses the declared tolerance. Storage savings depend on symmetry and sparsity, while dense materialization still requires the full ambient tensor size. The provenance registry records `PSC-III-D04P` as Sparse polynomial derivative provider. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · SparseSymmetricTensor

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SparseSymmetricTensor`. Reflected implementation `komorebi_math.nonlinear.sparse.SparseSymmetricTensor`. The same runtime object is also available through `komorebi_math.SparseSymmetricTensor`, `komorebi_math.beta.SparseSymmetricTensor`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SPARSE-TENSORS`.

Manifest signature (s).

```
(order: 'int', source_dimension: 'int', target_dimension: 'int', entries: 'tuple[SparseTensorEntry, ...]' = ()) ->
    ↪ None
```

Definition. One finite symmetric tensor stored by source-index orbits.

Contract (D, C, H, R, X). Sparse tensor records require nonnegative output indices, canonical nondecreasing source-index tuples, positive finite dimensions, and coefficients compatible with the selected exactness model. A sparse polynomial provider requires one finite tensor per declared derivative order and common source and target dimensions. Principal public operations and properties are `from_mapping`, `from_dense`, `stored_entry_count`, `dense_entry_count`, `expanded_nonzero_count`, `storage_ratio`, `contract`, `to_dense`, `certificate`, `to_dict`.

Guarantees (E, P, B, K). Orbit storage represents symmetric ordered tensor entries without storing every permutation. Contraction and dense reconstruction agree with the implemented orbit expansion. Exact object arithmetic remains exact when requested and supported. Numerical compression uses the declared tolerance. Storage savings depend on symmetry and sparsity, while dense materialization still requires the full ambient tensor size. The provenance registry records `PSC-III-D04S` as Sparse symmetric derivative tensor. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · SparseTensorEntry

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.SparseTensorEntry`. Reflected implementation `komorebi_math.nonlinear.sparse.SparseTensorEntry`. The same runtime object is also available through `komorebi_math.SparseTensorEntry`, `komorebi_math.beta.SparseTensorEntry`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-SPARSE-TENSORS`.

Manifest signature (s).

```
(output: 'int', inputs: 'tuple[int, ...]', value: 'Any') -> None
```

Definition. One coefficient of a symmetric tensor orbit.

Contract (D, C, H, R, X). Sparse tensor records require nonnegative output indices, canonical nondecreasing source-index tuples, positive finite dimensions, and coefficients compatible with the selected exactness model. A sparse polynomial provider requires one finite tensor per declared derivative order and common source and target dimensions.

Guarantees (E, P, B, K). Orbit storage represents symmetric ordered tensor entries without storing every permutation. Contraction and dense reconstruction agree with the implemented orbit expansion. Exact object arithmetic remains exact when requested and supported. Numerical compression uses the declared tolerance. Storage savings depend on symmetry and sparsity, while dense materialization still requires the full ambient tensor size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · StreamedPacketJetEvaluation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.StreamedPacketJetEvaluation`. Reflected implementation `komorebi_math.nonlinear.streaming.StreamedPacketJetEvaluation`. The same runtime object is also available through `komorebi_math.StreamedPacketJetEvaluation`, `komorebi_math.beta.StreamedPacketJetEvaluation`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(value: 'np.ndarray', coefficient_start: 'int', coefficient_stop: 'int', total_coefficients: 'int',
   ↪ complete_snapshot: 'bool', certificate: 'Certificate') -> None
```

Definition. One chunk-wise packet-jet evaluation with an explicit coverage record.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · TreeExpansionResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.TreeExpansionResult`. Reflected implementation `komorebi_math.nonlinear.trees.TreeExpansionResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(value: 'Any', picard_value: 'Any', terms: 'tuple[TreeTerm, ...]', depth: 'int', certificate: 'Certificate') ->
   ↪ None
```

Definition. Finite rooted-tree expansion compared with the matching Picard iterate.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity

for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · `TreeTerm`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.TreeTerm`. Reflected implementation `komorebi_math.nonlinear.trees.TreeTerm`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C5-ROOTED-TREES`.

Manifest signature (`s`).

```
(tree: 'OrderedRootedTree', value: 'Any') -> None
```

Definition. One ordered rooted tree and its evaluated contribution.

Contract (`D, C, H, R, X`). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (`E, P, B, K`). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · `capture_packet_jet_stream`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.capture_packet_jet_stream`. Reflected implementation `komorebi_math.nonlinear.streaming.capture_packet_jet_stream`. The same runtime object is also available through `komorebi_math.capture_packet_jet_stream`, `komorebi_math.beta.capture_packet_jet_stream`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-STREAMING`.

Manifest signature (`s`).

```
(jet: 'PacketJet', path: 'str | os.PathLike[str]', *, tolerance: 'float | None' = None, max_evaluations: 'int' =
    ↪ 10000000, chunk_size: 'int' = 1024, evaluation_budget: 'int | None' = None, resume: 'bool' = False,
    ↪ overwrite: 'bool' = False) -> 'PacketJetStreamWriteResult'
```

Definition. Capture a packet jet directly into bounded, resumable basis chunks.

Contract (`D, C, H, R, X`). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (`E, P, B, K`). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes. The provenance registry records `PSC-III-D60` as Chunked resumable packet-jet capture. Its recorded status is `finite certificate`. Recorded limitations are that integrity digests are not signatures and that resuming assumes the provider behavior still agrees with its recorded identity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `catalan_number`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.catalan_number`. Reflected implementation `komorebi_math.nonlinear.trees.catalan_number`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(index: 'int') -> 'int'
```

Definition. Return the exact Catalan number `C_index`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · `compile_packet_jet_plan`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.compile_packet_jet_plan`. Reflected implementation `komorebi_math.nonlinear.execution.compile_packet_jet_plan`. The same runtime object is also available through `komorebi_math.compile_packet_jet_plan, komorebi_math.beta.compile_packet_jet_plan`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', support: 'PacketJetSupport | None' = None, *, max_addresses: 'int' = 1000000) ->
    ↪ 'PacketJetExecutionPlan'
```

Definition. Compile a projection-cached plan, pruning only certified zero blocks.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is avail-

able. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `cupy_runtime_status`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.cupy_runtime_status`. Reflected implementation `komorebi_math.nonlinear.gpu.cupy_runtime_status`. The same runtime object is also available through `komorebi_math.cupy_runtime_status`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-GPU`.

Manifest signature (s).

```
() -> 'CuPyRuntimeStatus'
```

Definition. Inspect CuPy and CUDA availability without raising on absent hardware.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43. The recorded audit runtime had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.5B · `estimate_packet_jet_complexity`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.estimate_packet_jet_complexity`. Reflected implementation `komorebi_math.nonlinear.profiling.estimate_packet_jet_complexity`. The same runtime object is also available through `komorebi_math.estimate_packet_jet_complexity`, `komorebi_math.beta.estimate_packet_jet_complexity`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-PROFILING`.

Manifest signature (s).

```
(family: 'PacketJetFamily', support: 'PacketJetSupport | None' = None, *, plan: 'PacketJetExecutionPlan | None' =
    ↪ None, max_addresses: 'int' = 1000000) -> 'PacketJetComplexityEstimate'
```

Definition. Return exact finite operation counts for a packet-jet family.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · execute_packet_jet_plan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.execute_packet_jet_plan`. Reflected implementation `komorebi_math.nonlinear.execution.execute_packet_jet_plan`. The same runtime object is also available through `komorebi_math.execute_packet_jet_plan`, `komorebi_math.beta.execute_packet_jet_plan`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(plan: 'PacketJetExecutionPlan', family: 'PacketJetFamily', directions: 'Sequence[Any]', *, tolerance: 'float |
    ↪ None' = None) -> 'PacketJetBatchResult'
```

Definition. Execute a packet-jet plan with cached input projections.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · execute_packet_jets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.execute_packet_jets`. Reflected implementation `komorebi_math.nonlinear.execution.execute_packet_jets`. The same runtime object is also available through `komorebi_math.execute_packet_jets`, `komorebi_math.beta.execute_packet_jets`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', directions: 'Sequence[Any]', *, support: 'PacketJetSupport | None' = None, tolerance:
   ↪  'float | None' = None, max_addresses: 'int' = 1000000) -> 'PacketJetBatchResult'
```

Definition. Compile and execute one projection-cached packet-jet family.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · `load_packet_jet_snapshot_stream`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.load_packet_jet_snapshot_stream`. Reflected implementation `komorebi_math.nonlinear.streaming.load_packet_jet_snapshot_stream`. The same runtime object is also available through `komorebi_math.load_packet_jet_snapshot_stream`, `komorebi_math.beta.load_packet_jet_snapshot_stream`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(path: 'str | os.PathLike[str]', *, max_coefficients: 'int' = 1000000, verify_chunks: 'bool' = True) ->
   ↪  'PacketJetSnapshot'
```

Definition. Load a complete stream into a conventional in-memory snapshot.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · majorant_convergence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.majorant_convergence`. Reflected implementation `komorebi_math.nonlinear.trees.majorant_convergence`. The same runtime object is also available through `komorebi_math.majorant_convergence`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(seed_norm: 'float', operation_norms: 'Mapping[int, float]', radius: 'float', *, tolerance: 'float' = 1e-12) ->
    ↪ 'MajorantConvergence'
```

Definition. Validate `phi(R)<=R` and `sum r*b_r*R^(r-1)<1`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records `PSC-III-T14` as Polynomial rooted-tree convergence certificate. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · nonlinear_cupy_available

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.nonlinear_cupy_available`. Reflected implementation `komorebi_math.nonlinear.execution.nonlinear_cupy_available`. The same runtime object is also available through `komorebi_math.nonlinear_cupy_available`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
() -> 'bool'
```

Definition. Report whether a CuPy module can be discovered.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · ordered_rooted_trees

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ordered_rooted_trees`. Reflected implementation `komorebi_math.nonlinear.trees.ordered_rooted_trees`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(max_height: 'int', arities: 'Sequence[int]', *, max_trees: 'int' = 100000) -> 'tuple[OrderedRootedTree, ...]'
```

Definition. Enumerate all ordered rooted trees up to a height bound.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · ordered_tree_count

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ordered_tree_count`. Reflected implementation `komorebi_math.nonlinear.trees.ordered_tree_count`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(max_height: 'int', arities: 'Sequence[int]') -> 'int'
```

Definition. Count trees whose height is at most `max_height`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · ordered_trees_with_leaves

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.ordered_trees_with_leaves`. Reflected implementation `komorebi_math.nonlinear.trees.ordered_trees_with_leaves`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(leaves: 'int', arities: 'Sequence[int]', *, max_trees: 'int' = 100000) -> 'tuple[OrderedRootedTree, ...]'
```

Definition. Enumerate trees with exactly the requested number of leaves.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · packet_jet_benchmark_contract

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.packet_jet_benchmark_contract`. Reflected implementation `komorebi_math.nonlinear.execution.packet_jet_benchmark_contract`. The same runtime object is also available through `komorebi_math.packet_jet_benchmark_contract`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', *, backend: 'str', timing_scope: 'str' = 'kernel') -> 'Any'
```

Definition. Create a matched benchmark contract without importing algorithms eagerly.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · packet_jet_support

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.packet_jet_support`. Reflected implementation `komorebi_math.nonlinear.jets.packet_jet_support`. The same runtime object is also available through `komorebi_math.packet_jet_support`, `komorebi_math.beta.packet_jet_support`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
(family: 'PacketJetFamily', *, tolerance: 'float | None' = None, max_evaluations: 'int' = 100000) ->
    ↪ 'PacketJetSupport'
```

Definition. Classify packet jet blocks by exhaustive packet-range basis tests.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor

certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-C08` as Finite packet jet support test. Its recorded status is `finite certificate`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · packet_taylor

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.packet_taylor`. Reflected implementation `komorebi_math.nonlinear.jets.packet_taylor`. The same runtime object is also available through `komorebi_math.packet_taylor`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-PACKET-JETS`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', point: 'Any', increment: 'Any', source: 'PacketSystem', target: 'PacketSystem',
    ↪ order: 'int', *, tolerance: 'float | None' = None) -> 'PacketTaylorResult'
```

Definition. Assemble a finite Taylor polynomial through packet jet reconstruction.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-C09` as Finite packet Taylor reconstruction. Its recorded status is `finite certificate`. Recorded limitation: no automatic bound on the omitted Taylor remainder.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 38.

C.5B · packet_tree_reconstruction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.packet_tree_reconstruction`. Reflected implementation `komorebi_math.nonlinear.trees.packet_tree_reconstruction`. The same runtime object is also available through `komorebi_math.packet_tree_reconstruction`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (`s`).

```
(problem: 'PolynomialFixedPointProblem', tree: 'OrderedRootedTree', packets: 'PacketSystem', *, zero_support:
    ↪ 'Mapping[int, PacketJetSupport] | None' = None, tolerance: 'float | None' = None) -> 'PacketTreeResult'
```

Definition. Reconstruct one tree by summing packet labels at every vertex.

Contract (`D, C, H, R, X`). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (`E, P, B, K`). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records `PSC-III-T16` as Packet-labeled rooted-tree reconstruction. Its recorded status is `proved`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · `profile_operation`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.nonlinear.profile_operation`. Reflected implementation `komorebi_math.nonlinear.profiling.profile_operation`. The same runtime object is also available through `komorebi_math.profile_operation`, `komorebi_math.beta.profile_operation`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-PROFILING`.

Manifest signature (`s`).

```
(name: 'str', operation: 'Callable[[], T]', *, repetitions: 'int' = 5, warmup: 'int' = 1, scope: 'str' = 'Python
    ↪ call including allocations and synchronization performed by the callable') -> 'RuntimeStageProfile'
```

Definition. Observe one callable without interpreting timings as asymptotic evidence.

Contract (`D, C, H, R, X`). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (`E, P, B, K`). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · profile_packet_jet_runtime

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.profile_packet_jet_runtime`. Reflected implementation `komorebi_math.nonlinear.profiling.profile_packet_jet_runtime`. The same runtime object is also available through `komorebi_math.profile_packet_jet_runtime`, `komorebi_math.beta.profile_packet_jet_runtime`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-PROFILING`.

Manifest signature (s).

```
(family: 'PacketJetFamily', directions: 'Sequence[Any]', *, support: 'PacketJetSupport | None' = None, jet:
   ↪ 'PacketJet | None' = None, repetitions: 'int' = 5, warmup: 'int' = 1, max_addresses: 'int' = 1000000,
   ↪ max_snapshot_evaluations: 'int' = 100000, include_stream_write: 'bool' = False, stream_chunk_size: 'int' =
   ↪ 1024) -> 'PacketJetProfileReport'
```

Definition. Profile selected packet-jet stages under one explicit local contract.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements. The provenance registry records `PSC-III-A61` as Finite packet-jet execution profile. Its recorded status is `heuristic`. Recorded limitations are that timings depend on the environment and that tracemalloc observes Python-managed allocations rather than total device or process memory.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · quadratic_catalan_majorant

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.quadratic_catalan_majorant`. Reflected implementation `komorebi_math.nonlinear.trees.quadratic_catalan_majorant`. The same runtime object is also available through `komorebi_math.quadratic_catalan_majorant`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-ROOTED-TREES`.

Manifest signature (s).

```
(seed_norm: 'float', bilinear_norm: 'float', *, tolerance: 'float' = 1e-12) -> 'MajorantConvergence'
```

Definition. Construct the sharp small-root majorant for `u=s+B(u,u)`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 39.

C.5B · require

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.require`. Reflected implementation `komorebi_math.nonlinear.require`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-NAMESPACE`.

Manifest signature (s).

```
() -> None
```

Definition. Confirm that the implemented nonlinear calculus is available.

Contract (D, C, H, R, X). The namespace marker is the literal feature key used by the registry. The `require` route takes no arguments and returns successfully for this implemented package component. Neither contract imports optional GPU runtimes or changes global state.

Guarantees (E, P, B, K). The feature key is deterministic for the installed source tree. The availability check has constant auxiliary storage and makes no statement about optional devices, performance, or the validity of a particular nonlinear model.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_certificates_registry.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 6.

C.5B · save_packet_jet_snapshot_stream

Identity (q, a, t, k). Public research-manifest route `komorebi_math.nonlinear.save_packet_jet_snapshot_stream`. Reflected implementation `komorebi_math.nonlinear.streaming.save_packet_jet_snapshot_stream`. The same runtime object is also available through `komorebi_math.save_packet_jet_snapshot_stream`, `komorebi_math.beta.save_packet_jet_snapshot_stream`. The `komorebi_math.nonlinear` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C5-STREAMING`.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', path: 'str | os.PathLike[str]', *, chunk_size: 'int' = 1024, coefficient_budget:
    ↪  'int | None' = None, resume: 'bool' = False, overwrite: 'bool' = False) -> 'PacketJetStreamWriteResult'
```

Definition. Write an existing snapshot as independently verified coefficient chunks.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migratio`

ns.py. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43.

C.5B · snapshot_packet_jet

Identity (q, a, t, k). Public research-manifest route komorebi_math.nonlinear.snapshot_packet_jet. Reflected implementation komorebi_math.nonlinear.snapshots.snapshot_packet_jet. The same runtime object is also available through komorebi_math.snapshot_packet_jet, komorebi_math.beta.snapshot_packet_jet. The komorebi_math.nonlinear route is governed by [RESEARCH] policy pre-beta-additive. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind function. Profile C5-SNAPSHOTS.

Manifest signature (s).

```
(jet: 'PacketJet', *, tolerance: 'float | None' = None, max_evaluations: 'int' = 100000) -> 'PacketJetSnapshot'
```

Definition. Capture one packet jet by exhaustive standard-basis evaluation.

Contract (D, C, H, R, X). A snapshot captures one fixed packet jet by evaluating the ambient standard-basis tuples through an explicit finite budget. The source and target dimensions, base point, address, provider name, exactness, and sparse coefficients are stored in the record. Snapshot evaluation requires direction vectors of the recorded source dimension.

Guarantees (E, P, B, K). The snapshot is provider-independent after capture and reconstructs the recorded multilinear block from its stored coefficients. Its comparison certificate checks matched evaluations against the source jet on supplied probes. Exact coefficients preserve exact arithmetic. Numerical coefficients use the stored tolerance and certificate. Dense capture cost grows as the source dimension raised to the jet order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are tests/test_nonlinear_snapshots_persistence.py and tests/test_block10_execution_persistence.py. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 38 and 43.

C.5B · validate_cupy_snapshot

Identity (q, a, t, k). Public research-manifest route komorebi_math.nonlinear.validate_cupy_snapshot. Reflected implementation komorebi_math.nonlinear.gpu.validate_cupy_snapshot. The same runtime object is also available through komorebi_math.validate_cupy_snapshot. The komorebi_math.nonlinear route is governed by [RESEARCH] policy pre-beta-additive. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind function. Profile C5-GPU.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', probes: 'Sequence[Sequence[Any]]', *, tolerance: 'float' = 1e-09) ->
    ↪ 'CuPyValidationResult'
```

Definition. Compare matched CPU and CuPy evaluations on explicit probes.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear execution exercises representative finite identities, rejection paths, implementation ownership, alias behavior, and persistence integrity for this contract family. The source validator for nonlinear execution checks the exact signature, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 43. The recorded audit runtime had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

> **Nonlinear execution reference.** The 69 cards in C.5B cover 37 classes, 25 functions, and 7 data exports. Together with C.5A, they document all 149 entries in the nonlinear namespace. Their recorded audit includes packet-jet and persistence checks alongside manifest and runtime identity checks.

C.6 `komorebi_math.export`: 58 entries

The export namespace connects finite mathematical values to typed reports, readable renderings, controlled filesystem outputs, local LaTeX compilation, and strict portable reconstruction. These contracts deliberately keep presentation serialization separate from portable persistence. A readable JSON or Markdown export is not automatically a reconstruction format, while a portable envelope is not automatically a polished report.

Contract family	Cards
Typed document model	10
Presentation serialization and adapters	6
Text, Markdown, HTML, and LaTeX renderers	8
File writers, formats, and deterministic bundles	10
Local LaTeX compilation	6
Report builders	3
Portable codecs, migrations, envelopes, and atomic files	15
Total	**58**

The boundary is explicit. Ordinary renderer text is escaped, while equation source and `RawLatex` remain trusted input. File writers enforce destination policy but do not authenticate content. Portable digests detect changes under a fixed codec contract but do not provide encryption or a keyed signature. PDF creation depends on a supported local LaTeX engine.

C.6 · `CodeBlock`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.CodeBlock`. Reflected implementation `komorebi_math.export.model.CodeBlock`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(code: 'str', language: 'str' = 'text', caption: 'str | None' = None) -> None
```

Definition. A literal code block.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does

not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `DocumentMetadata`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.DocumentMetadata`. Reflected implementation `komorebi_math.export.model.DocumentMetadata`. The same runtime object is also available through `komorebi_math.DocumentMetadata`, `komorebi_math.stable.DocumentMetadata`, `komorebi_math.v1.DocumentMetadata`, `komorebi_math.api.v1.DocumentMetadata`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(title: 'str' = 'Komorebi Math Export', author: 'str | None' = None, date: 'str | None' = None, abstract: 'str |
   ↪ None' = None, keywords: 'tuple[str, ...]' = ()) -> None
```

Definition. Metadata used by Markdown, HTML, and LaTeX document renderers.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `Equation`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.Equation`. Reflected implementation `komorebi_math.export.model.Equation`. The same runtime object is also available through `komorebi_math.Equation`, `komorebi_math.stable.Equation`, `komorebi_math.v1.Equation`, `komorebi_math.api.v1.Equation`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(latex: 'str', label: 'str | None' = None, numbered: 'bool' = False, description: 'str | None' = None) -> None
```

Definition. One LaTeX mathematical expression.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but

file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (`E`, `P`, `B`, `K`). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `ExportBundleResult`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.export.ExportBundleResult`. Reflected implementation `komorebi_math.export.writers.ExportBundleResult`. The same runtime object is also available through `komorebi_math.ExportBundleResult`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-WRITERS`.

Manifest signature (`s`).

```
(path: 'Path', members: 'tuple[str, ...]', formats: 'tuple[ExportFormat, ...]', manifest_path: 'Path',
   ↪ certificate: 'Certificate') -> None
```

Definition. A ZIP bundle containing several exports and a hash manifest.

Contract (`D`, `C`, `H`, `R`, `X`). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`. Principal public operations and properties are `valid`, `require`.

Guarantees (`E`, `P`, `B`, `K`). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `ExportFormat`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.export.ExportFormat`. Reflected implementation `komorebi_math.export.writers.ExportFormat`. The same runtime object is also available through `komorebi_math.ExportFormat`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-WRITERS`.

Manifest signature (`s`).

```
(*values)
```

Definition. Enumeration of the 11 supported on-disk formats: JSON, YAML, CSV, TSV, text, Markdown, HTML, LaTeX, PDF, NPY, and NPZ.

Contract (`D, C, H, R, X`). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (`E, P, B, K`). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `ExportOptions`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.export.ExportOptions`. Reflected implementation `komorebi_math.export.writers.ExportOptions`. The same runtime object is also available through `komorebi_math.ExportOptions`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-WRITERS`.

Manifest signature (`s`).

```
(title: 'str' = 'Komorebi Math Export', author: 'str | None' = None, date: 'str | None' = None, abstract: 'str |
    ↪ None' = None, overwrite: 'bool' = False, create_parents: 'bool' = True, preserve_types: 'bool' = True,
    ↪ json_indent: 'int' = 2, include_certificate: 'bool' = True, keep_tex: 'bool' = True, html:
    ↪ 'HtmlRenderOptions' = <factory>, latex: 'LatexRenderOptions' = <factory>, compiler: 'LatexCompileOptions' =
    ↪ <factory>) -> None
```

Definition. Common export behavior and renderer options.

Contract (`D, C, H, R, X`). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (`E, P, B, K`). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · ExportResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.ExportResult`. Reflected implementation `komorebi_math.export.writers.ExportResult`. The same runtime object is also available through `komorebi_math.ExportResult`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-WRITERS`.

Manifest signature (s).

```
(path: 'Path', format: 'ExportFormat', bytes_written: 'int', companion_files: 'tuple[Path, ...]', certificate:
    ↪ 'Certificate') -> None
```

Definition. One completed file export and its validation certificate.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`. Principal public operations and properties are `valid`, `require`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · Exportable

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.Exportable`. Reflected implementation `komorebi_math.export.serialization.Exportable`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-SERIALIZATION`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Runtime-checkable protocol for objects that provide a recursively normalizable `to_export_data()` representation.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing `Exportable`. Recursion is bounded by `max_depth`. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings. Principal public operations and properties are `to_export_data`.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by `repr`, and arbitrary class names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_serialization.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection

paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 59 and 60.

C.6 · Figure

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.Figure`. Reflected implementation `komorebi_math.export.model.Figure`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(path: 'Path', caption: 'str | None' = None, label: 'str | None' = None, width: 'str' = '0.9\\textwidth') -> None
```

Definition. A figure file referenced by a document.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · Heading

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.Heading`. Reflected implementation `komorebi_math.export.model.Heading`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(text: 'str', level: 'int' = 1, label: 'str | None' = None) -> None
```

Definition. One document heading.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks

the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · HtmlRenderOptions

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.HtmlRenderOptions`. Reflected implementation `komorebi_math.export.renderers.HtmlRenderOptions`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(include_mathjax: 'bool' = False, title: 'str | None' = None) -> None
```

Definition. Configuration for standalone HTML exports.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · LatexCompilation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.LatexCompilation`. Reflected implementation `komorebi_math.export.latex.LatexCompilation`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-LATEX-COMPILATION`.

Manifest signature (s).

```
(source_path: 'Path', pdf_path: 'Path | None', log_path: 'Path', engine: 'LatexEngine', commands:
   ↪ 'tuple[tuple[str, ...], ...]', return_codes: 'tuple[int, ...]', certificate: 'Certificate') -> None
```

Definition. Paths, logs, and certificate returned by a LaTeX compilation.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory. Principal public operations and properties are `valid`, `require`.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration,

compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60. The recorded audit runtime exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.6 · `LatexCompileOptions`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.export.LatexCompileOptions`. Reflected implementation `komorebi_math.export.latex.LatexCompileOptions`. The same runtime object is also available through `komorebi_math.LatexCompileOptions`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-LATEX-COMPILATION`.

Manifest signature (`s`).

```
(engine: 'LatexEngine | str' = <LatexEngine.AUTO: 'auto'>, passes: 'int' = 2, timeout: 'float' = 120.0,
    ↪ shell_escape: 'bool' = False, keep_auxiliary: 'bool' = False, jobname: 'str | None' = None) -> None
```

Definition. Options for one isolated LaTeX compilation.

Contract (`D, C, H, R, X`). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (`E, P, B, K`). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60. The recorded audit runtime exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.6 · `LatexEngine`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.export.LatexEngine`. Reflected implementation `komorebi_math.export.latex.LatexEngine`. The same runtime object is also available through `komorebi_math.LatexEngine`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-LATEX-COMPILATION`.

Manifest signature (`s`).

```
(*values)
```

Definition. Enumeration of automatic, pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk compiler choices.

Contract (`D, C, H, R, X`). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (`E, P, B, K`). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60. The recorded audit runtime exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.6 · `LatexRenderOptions`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.LatexRenderOptions`. Reflected implementation `komorebi_math.export.renderers.LatexRenderOptions`. The same runtime object is also available through `komorebi_math.LatexRenderOptions`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(document_class: 'str' = 'article', class_options: 'tuple[str, ...]' = ('11pt',), packages: 'tuple[str, ...]' =
    ↪ ('amsmath', 'amssymb', 'booktabs', 'longtable', 'array', 'graphicx', 'hyperref', 'geometry', 'microtype'),
    ↪ include_table_of_contents: 'bool' = False, number_sections: 'bool' = True, geometry: 'str' = 'margin=1in')
    ↪ -> None
```

Definition. Configuration for generated LaTeX documents.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `ListBlock`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.ListBlock`. Reflected implementation `komorebi_math.export.model.ListBlock`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(items: 'tuple[str, ...]', ordered: 'bool' = False) -> None
```

Definition. An ordered or unordered list.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does

not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `MathDocument`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.MathDocument`. Reflected implementation `komorebi_math.export.model.MathDocument`. The same runtime object is also available through `komorebi_math.MathDocument`, `komorebi_math.stable.MathDocument`, `komorebi_math.v1.MathDocument`, `komorebi_math.api.v1.MathDocument`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(metadata: 'DocumentMetadata' = <factory>, blocks: 'list[DocumentBlock]' = <factory>) -> None
```

Definition. A renderer independent mathematical document.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods. Principal public operations and properties are `add`, `section`, `paragraph`, `equation`, `table`, `code`, `bullet_list`, `figure`.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `PORTABLE_SCHEMA`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.PORTABLE_SCHEMA`. Reflected implementation `builtins.str`. The same runtime object is also available through `komorebi_math.stable.PORTABLE_SCHEMA`, `komorebi_math.beta.PORTABLE_SCHEMA`, `komorebi_math.v1.PORTABLE_SCHEMA`, `komorebi_math.api.v1.PORTABLE_SCHEMA`. The public export name maps to implementation object `str`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
null
```

Definition. Literal portable-envelope schema identifier `komorebi-math.portable`.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256.

Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `PORTABLE_SCHEMA_VERSION`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.PORTABLE_SCHEMA_VERSION`. Reflected implementation `builtins.int`. The same runtime object is also available through `komorebi_math.stable.PORTABLE_SCHEMA_VERSION`, `komorebi_math.beta.PORTABLE_SCHEMA_VERSION`, `komorebi_math.v1.PORTABLE_SCHEMA_VERSION`, `komorebi_math.api.v1.PORTABLE_SCHEMA_VERSION`. The public export name maps to implementation object `int`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
null
```

Definition. Current integer version of the portable-envelope schema. The committed value is `1`.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `Paragraph`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.Paragraph`. Reflected implementation `komorebi_math.export.model.Paragraph`. The same runtime object is also available through `komorebi_math.stable.Paragraph`, `komorebi_math.v1.Paragraph`, `komorebi_math.api.v1.Paragraph`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(text: 'str') -> None
```

Definition. One prose paragraph whose text is escaped by each renderer.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `PortableCodec`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.PortableCodec`. Reflected implementation `komorebi_math.export.persistence.PortableCodec`. The same runtime object is also available through `komorebi_math.PortableCodec`, `komorebi_math.stable.PortableCodec`, `komorebi_math.beta.PortableCodec`, `komorebi_math.v1.PortableCodec`, `komorebi_math.api.v1.PortableCodec`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(tag: 'str', version: 'int', type_: 'type[Any]', encoder: 'Encoder', decoder: 'Decoder') -> None
```

Definition. One explicit type codec in the portable persistence registry.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · PortableMigration

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.PortableMigration`. Reflected implementation `komorebi_math.export.persistence.PortableMigration`. The same runtime object is also available through `komorebi_math.PortableMigration`, `komorebi_math.stable.PortableMigration`, `komorebi_math.beta.PortableMigration`, `komorebi_math.v1.PortableMigration`, `komorebi_math.api.v1.PortableMigration`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(tag: 'str', from_version: 'int', to_version: 'int', migrator: 'Migrator') -> None
```

Definition. One explicit, adjacent codec-data migration.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · RawLatex

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.RawLatex`. Reflected implementation `komorebi_math.export.model.RawLatex`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(source: 'str') -> None
```

Definition. A deliberate trusted-source escape hatch inserted unchanged by the LaTeX renderer and shown as literal code by the other renderers.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `Table`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.Table`. Reflected implementation `komorebi_math.export.model.Table`. The same runtime object is also available through `komorebi_math.Table`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C6-DOCUMENT-MODEL`.

Manifest signature (s).

```
(headers: 'tuple[str, ...]', rows: 'tuple[tuple[Any, ...], ...]', caption: 'str | None' = None, label: 'str | None'
   ↪  = None, alignment: 'tuple[str, ...] | None' = None) -> None
```

Definition. A rectangular table with optional caption and label.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods. Principal public operations and properties are `from_rows`.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `available_export_formats`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.available_export_formats`. Reflected implementation `komorebi_math.export.writers.available_export_formats`. The same runtime object is also available through `komorebi_math.available_export_formats`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-WRITERS`.

Manifest signature (s).

```
() -> 'tuple[str, ...]'
```

Definition. Return every supported public format name.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle

manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `available_latex_engines`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.available_latex_engines`. Reflected implementation `komorebi_math.export.latex.available_latex_engines`. The same runtime object is also available through `komorebi_math.available_latex_engines`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-LATEX-COMPILATION`.

Manifest signature (s).

```
() -> 'dict[str, bool]'
```

Definition. Report which supported LaTeX commands are available on PATH.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60. The recorded audit runtime exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.6 · `certificate_document`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.certificate_document`. Reflected implementation `komorebi_math.export.report.certificate_document`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-REPORT-BUILDERS`.

Manifest signature (s).

```
(certificate: 'Certificate', *, title: 'str' = 'Certificate') -> 'MathDocument'
```

Definition. Build a compact document describing one certificate.

Contract (D, C, H, R, X). Report builders convert certificates, finite sequences, and common Python data into the typed document model. Existing `MathDocument` values pass through unchanged. Result records may contribute their certificate when `include_certificate` is enabled. Mappings, short arrays, sequences, and dataclasses are converted to tables when possible, while unsupported table shapes fall back to normalized JSON code.

Guarantees (E, P, B, K). The builders preserve visible validity, exactness, tolerances, residuals, assumptions, and diagnostics when those fields exist. They produce readable reports rather than portable reconstruction records. A report can summarize evidence, but creating the report does not independently validate the source object or certificate.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `compile_latex`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.compile_latex`. Reflected implementation `komorebi_math.export.latex.compile_latex`. The same runtime object is also available through `komorebi_math.compile_latex`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-LATEX-COMPILATION`.

Manifest signature (s).

```
(source: 'str | Path', output_dir: 'str | Path', *, options: 'LatexCompileOptions | None' = None, source_name:
    ↪ 'str' = 'document.tex') -> 'LatexCompilation'
```

Definition. Compile LaTeX source to PDF without enabling shell escape by default.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60. The recorded audit runtime exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.6 · `document_from_data`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.document_from_data`. Reflected implementation `komorebi_math.export.report.document_from_data`. The same runtime object is also available through `komorebi_math.document_from_data`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-REPORT-BUILDERS`.

Manifest signature (s).

```
(value: 'Any', *, title: 'str' = 'Komorebi Math Export', author: 'str | None' = None, date: 'str | None' = None,
    ↪ abstract: 'str | None' = None, include_certificate: 'bool' = True) -> 'MathDocument'
```

Definition. Create a readable mathematical document from common Python data.

Contract (D, C, H, R, X). Report builders convert certificates, finite sequences, and common Python data into the typed document model. Existing `MathDocument` values pass through unchanged. Result records may contribute their cer-

tificate when `include_certificate` is enabled. Mappings, short arrays, sequences, and dataclasses are converted to tables when possible, while unsupported table shapes fall back to normalized JSON code.

Guarantees (`E`, `P`, `B`, `K`). The builders preserve visible validity, exactness, tolerances, residuals, assumptions, and diagnostics when those fields exist. They produce readable reports rather than portable reconstruction records. A report can summarize evidence, but creating the report does not independently validate the source object or certificate.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · `dumps_portable`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.export.dumps_portable`. Reflected implementation `komorebi_math.export.persistence.dumps_portable`. The same runtime object is also available through `komorebi_math.dumps_portable`, `komorebi_math.stable.dumps_portable`, `komorebi_math.beta.dumps_portable`, `komorebi_math.v1.dumps_portable`, `komorebi_math.api.v1.dumps_portable`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (`s`).

```
(value: 'Any', *, indent: 'int | None' = 2, max_depth: 'int' = 128) -> 'str'
```

Definition. Serialize one value into a complete digest-checked JSON envelope.

Contract (`D`, `C`, `H`, `R`, `X`). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (`E`, `P`, `B`, `K`). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `export_adapters`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.export.export_adapters`. Reflected implementation `komorebi_math.export.serialization.export_adapters`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-SERIALIZATION`.

Manifest signature (s).

```
() -> 'dict[type[Any], ExportAdapter]'
```

Definition. Return a copy of the active export adapter registry.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing `Exportable`. Recursion is bounded by `max_depth`. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by `repr`, and arbitrary class names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_serialization.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 59 and 60.

C.6 · `export_bundle`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.export_bundle`. Reflected implementation `komorebi_math.export.writers.export_bundle`. The same runtime object is also available through `komorebi_math.export_bundle`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-WRITERS`.

Manifest signature (s).

```
(value: 'Any', path: 'str | Path', *, base_name: 'str' = 'komorebi_export', formats: 'Sequence[ExportFormat | str]'
    ↪ = (<ExportFormat.JSON: 'json'>, <ExportFormat.MARKDOWN: 'markdown'>, <ExportFormat.LATEX: 'latex'>),
    ↪ options: 'ExportOptions | None' = None) -> 'ExportBundleResult'
```

Definition. Create a ZIP archive with several exports and a SHA256 manifest.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · export_data

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.export_data`. Reflected implementation `komorebi_math.export.writers.export_data`. The same runtime object is also available through `komorebi_math.export_data`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-WRITERS`.

Manifest signature (s).

```
(value: 'Any', path: 'str | Path', *, format: 'ExportFormat | str | None' = None, options: 'ExportOptions | None' =
    ↪ None) -> 'ExportResult'
```

Definition. Export one Python or Komorebi Math value to a selected file format.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · export_document

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.export_document`. Reflected implementation `komorebi_math.export.writers.export_document`. The same runtime object is also available through `komorebi_math.export_document`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-WRITERS`.

Manifest signature (s).

```
(document: 'MathDocument', path: 'str | Path', *, format: 'ExportFormat | str | None' = None, options:
    ↪ 'ExportOptions | None' = None) -> 'ExportResult'
```

Definition. Export one renderer independent mathematical document.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the

exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · export_many

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.export_many`. Reflected implementation `komorebi_math.export.writers.export_many`. The same runtime object is also available through `komorebi_math.export_many`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-WRITERS`.

Manifest signature (s).

```
(value: 'Any', directory: 'str | Path', *, base_name: 'str', formats: 'Sequence[ExportFormat | str]', options:
    ↪ 'ExportOptions | None' = None) -> 'tuple[ExportResult, ...]'
```

Definition. Export one value into several formats inside one directory.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · from_portable_data

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.from_portable_data`. Reflected implementation `komorebi_math.export.persistence.from_portable_data`. The same runtime object is also available through `komorebi_math.stable.from_portable_data`, `komorebi_math.beta.from_portable_data`, `komorebi_math.v1.from_portable_data`, `komorebi_math.api.v1.from_portable_data`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(value: 'Any', *, max_depth: 'int' = 128) -> 'Any'
```

Definition. Decode one previously encoded portable payload tree.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `from_serializable`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.from_serializable`. Reflected implementation `komorebi_math.export.serialization.from_serializable`. The same runtime object is also available through `komorebi_math.from_serializable`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-SERIALIZATION`.

Manifest signature (s).

```
(value: 'Any', *, max_depth: 'int' = 64, _depth: 'int' = 0) -> 'Any'
```

Definition. Decode the safe built-in type markers emitted by `to_serializable`.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing `Exportable`. Recursion is bounded by `max_depth`. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by `repr`, and arbitrary class names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_serialization.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 59 and 60.

C.6 · `infer_export_format`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.infer_export_format`. Reflected implementation `komorebi_math.export.writers.infer_export_format`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-WRITERS`.

Manifest signature (s).

```
(path: 'str | Path') -> 'ExportFormat'
```

Definition. Infer an export format from a file suffix.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle

manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · latex_escape

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.latex_escape`. Reflected implementation `komorebi_math.export.renderers.latex_escape`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(value: 'Any') -> 'str'
```

Definition. Escape ordinary text for safe inclusion in LaTeX.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · latex_label

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.latex_label`. Reflected implementation `komorebi_math.export.renderers.latex_label`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(value: 'str') -> 'str'
```

Definition. Normalize a user label to a conservative LaTeX label.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering

performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `load_portable`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.load_portable`. Reflected implementation `komorebi_math.export.persistence.load_portable`. The same runtime object is also available through `komorebi_math.load_portable`, `komorebi_math.stable.load_portable`, `komorebi_math.beta.load_portable`, `komorebi_math.v1.load_portable`, `komorebi_math.api.v1.load_portable`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(path: 'str | os.PathLike[str]', *, max_depth: 'int' = 128) -> 'Any'
```

Definition. Read and validate a portable envelope from disk.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `loads_portable`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.loads_portable`. Reflected implementation `komorebi_math.export.persistence.loads_portable`. The same runtime object is also available through `komorebi_math.loads_portable`, `komorebi_math.stable.loads_portable`, `komorebi_math.beta.loads_portable`, `komorebi_math.v1.loads_portable`, `komorebi_math.api.v1.loads_portable`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(text: 'str | bytes', *, max_depth: 'int' = 128) -> 'Any'
```

Definition. Validate and deserialize one complete portable JSON envelope.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `portable_codecs`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.portable_codecs`. Reflected implementation `komorebi_math.export.persistence.portable_codecs`. The same runtime object is also available through `komorebi_math.portable_codecs`, `komorebi_math.stable.portable_codecs`, `komorebi_math.beta.portable_codecs`, `komorebi_math.v1.portable_codecs`, `komorebi_math.api.v1.portable_codecs`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
() -> 'tuple[PortableCodec, ...]'
```

Definition. Return the active codecs ordered by stable tag.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · portable_digest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.portable_digest`. Reflected implementation `komorebi_math.export.persistence.portable_digest`. The same runtime object is also available through `komorebi_math.portable_digest`, `komorebi_math.stable.portable_digest`, `komorebi_math.beta.portable_digest`, `komorebi_math.v1.portable_digest`, `komorebi_math.api.v1.portable_digest`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(value: 'Any', *, max_depth: 'int' = 128) -> 'str'
```

Definition. Return the canonical SHA256 digest of one encoded payload.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · portable_migrations

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.portable_migrations`. Reflected implementation `komorebi_math.export.persistence.portable_migrations`. The same runtime object is also available through `komorebi_math.portable_migrations`, `komorebi_math.stable.portable_migrations`, `komorebi_math.beta.portable_migrations`, `komorebi_math.v1.portable_migrations`, `komorebi_math.api.v1.portable_migrations`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
() -> 'tuple[PortableMigration, ...]'
```

Definition. Return registered codec migrations in deterministic order.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `register_export_adapter`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.register_export_adapter`. Reflected implementation `komorebi_math.export.serialization.register_export_adapter`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-SERIALIZATION`.

Manifest signature (s).

```
(type_: 'type[T]', adapter: 'Callable[[T], Any]', *, replace: 'bool' = False) -> 'None'
```

Definition. Register a normalization adapter for one Python type.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing `Exportable`. Recursion is bounded by `max_depth`. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by `repr`, and arbitrary class names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_serialization.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 59 and 60.

C.6 · `register_portable_codec`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.register_portable_codec`. Reflected implementation `komorebi_math.export.persistence.register_portable_codec`. The same runtime object is also available through `komorebi_math.register_portable_codec`, `komorebi_math.beta.register_portable_codec`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(type_: 'type[T]', *, tag: 'str', version: 'int', encoder: 'Callable[[T], Any]', decoder: 'Callable[[Any], T]',
   ↪ replace: 'bool' = False) -> 'None'
```

Definition. Register one stable round-trip codec.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `register_portable_migration`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.register_portable_migration`. Reflected implementation `komorebi_math.export.persistence.register_portable_migration`. The same runtime object is also available through `komorebi_math.register_portable_migration`, `komorebi_math.beta.register_portable_migration`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(*, tag: 'str', from_version: 'int', to_version: 'int', migrator: 'Migrator', replace: 'bool' = False) -> 'None'
```

Definition. Register one deterministic adjacent migration for codec data.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · `render_html`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.render_html`. Reflected implementation `komorebi_math.export.renderers.render_html`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(document: 'MathDocument', *, options: 'HtmlRenderOptions | None' = None) -> 'str'
```

Definition. Render a standalone HTML document.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `render_latex`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.render_latex`. Reflected implementation `komorebi_math.export.renderers.render_latex`. The same runtime object is also available through `komorebi_math.render_latex`, `komorebi_math.stable.render_latex`, `komorebi_math.v1.render_latex`, `komorebi_math.api.v1.render_latex`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(document: 'MathDocument', *, options: 'LatexRenderOptions | None' = None) -> 'str'
```

Definition. Render a complete compilable LaTeX document.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `render_markdown`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.render_markdown`. Reflected implementation `komorebi_math.export.renderers.render_markdown`. The same runtime object is also available through `komorebi_math.stable.render_markdown`, `komorebi_math.v1.render_markdown`, `komorebi_math.api.v1.render_markdown`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(document: 'MathDocument') -> 'str'
```

Definition. Render a document as Markdown with TeX equations.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `render_text`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.render_text`. Reflected implementation `komorebi_math.export.renderers.render_text`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-RENDERERS`.

Manifest signature (s).

```
(document: 'MathDocument') -> 'str'
```

Definition. Render a document as plain UTF-8 text.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_renderers.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60.

C.6 · `resolve_latex_engine`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.resolve_latex_engine`. Reflected implementation `komorebi_math.export.latex.resolve_latex_engine`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-LATEX-COMPILATION`.

Manifest signature (s).

```
(engine: 'LatexEngine | str' = <LatexEngine.AUTO: 'auto'>) -> 'LatexEngine'
```

Definition. Resolve an explicit or automatic LaTeX engine choice.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 60. The recorded audit runtime exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.6 · `save_portable`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.save_portable`. Reflected implementation `komorebi_math.export.persistence.save_portable`. The same runtime object is also available through `komorebi_math.save_portable`, `komorebi_math.stable.save_portable`, `komorebi_math.beta.save_portable`, `komorebi_math.v1.save_portable`, `komorebi_math.api.v1.save_portable`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(value: 'Any', path: 'str | os.PathLike[str]', *, overwrite: 'bool' = False, indent: 'int | None' = 2, max_depth:
    ↪ 'int' = 128) -> 'Path'
```

Definition. Atomically write a portable envelope to disk.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · sequence_document

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.sequence_document`. Reflected implementation `komorebi_math.export.report.sequence_document`. The same runtime object is also available through `komorebi_math.sequence_document`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-REPORT-BUILDERS`.

Manifest signature (s).

```
(name: 'str', values: 'Sequence[Any]', *, strategy: 'str | None' = None, modulus: 'int | None' = None, author: 'str
    ↪ | None' = None) -> 'MathDocument'
```

Definition. Build a table report for one executable sequence.

Contract (D, C, H, R, X). Report builders convert certificates, finite sequences, and common Python data into the typed document model. Existing `MathDocument` values pass through unchanged. Result records may contribute their certificate when `include_certificate` is enabled. Mappings, short arrays, sequences, and dataclasses are converted to tables when possible, while unsupported table shapes fall back to normalized JSON code.

Guarantees (E, P, B, K). The builders preserve visible validity, exactness, tolerances, residuals, assumptions, and diagnostics when those fields exist. They produce readable reports rather than portable reconstruction records. A report can summarize evidence, but creating the report does not independently validate the source object or certificate.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 59.

C.6 · table_rows

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.table_rows`. Reflected implementation `komorebi_math.export.serialization.table_rows`. No root, stable, beta, or versioned facade exports this domain-only name in the reference manifest. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-SERIALIZATION`.

Manifest signature (s).

```
(value: 'Any') -> 'tuple[tuple[str, ...], tuple[tuple[Any, ...], ...]]'
```

Definition. Convert a table shaped value to headers and rows.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing `Exportable`. Recursion is bounded by `max_depth`. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by `repr`, and arbitrary class names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_serialization.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 59 and 60.

C.6 · to_portable_data

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.to_portable_data`. Reflected implementation `komorebi_math.export.persistence.to_portable_data`. The same runtime object is also available through `komorebi_math.stable.to_portable_data`, `komorebi_math.beta.to_portable_data`, `komorebi_math.v1.to_portable_data`, `komorebi_math.api.v1.to_portable_data`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-PORTABLE-PERSISTENCE`.

Manifest signature (s).

```
(value: 'Any', *, max_depth: 'int' = 128) -> 'Any'
```

Definition. Encode one value into the versioned portable payload tree.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapter 61.

C.6 · to_serializable

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export.to_serializable`. Reflected implementation `komorebi_math.export.serialization.to_serializable`. The same runtime object is also available through `komorebi_math.to_serializable`. The `komorebi_math.export` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C6-SERIALIZATION`.

Manifest signature (s).

```
(value: 'Any', *, preserve_types: 'bool' = True, max_depth: 'int' = 64, _depth: 'int' = 0) -> 'Any'
```

Definition. Convert package and scientific Python objects to JSON compatible data.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing `Exportable`. Recursion is bounded by `max_depth`. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by `repr`, and arbitrary class names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_export_serialization.py`. The independent verifier for export and persistence exercises representative construction, rendering, serialization, file-policy, digest, migration, compilation, and rejection paths for this contract family. The source validator for export and persistence checks the exact signature, implementation identity, cumulative counts, unique anchor, and preservation of earlier cards. See Chapters 59 and 60.

Research reference coverage. The appendix contains all 1,312 research cards, including 516 root cards and every domain namespace. The four indexes below are derived from those cards and the reference manifests.

C.7 Canonical implementation-owner index across 201 research owners

The research manifest resolves its 1,312 namespace and name pairs to 201 implementation-owner strings. Of these, 196 are owned by the package and 5 come from Python or typing support modules. The package-owned set consists of 194 concrete source modules and the two package initializers `komorebi_math.nonlinear` and `komorebi_math.signals`. This index is scoped to Appendix C. The union across the stable, beta, and research manifests contains 207 distinct owners because six compatibility and exception modules occur only in the curated tiers.

Owner family	Owners	Research cards
`config`	1	4
`certificates`	1	4
`compatibility`	1	14
`golden`	1	4
`provenance`	1	3
`registry`	1	4
`unified`	1	3
`core`	9	25
`algorithms`	9	19
`arithmetic`	7	10
`sequences`	5	11
`analytic`	5	11
`refinement`	7	12
`coordinates`	23	278
`generating`	21	206
`signals`	21	162
`nonlinear`	22	229
`integration`	7	38
`dynamics`	7	7
`quantum`	11	12
`deformation`	5	6
`langlands`	17	28
`expression`	6	77
`export`	7	90
`external owners`	5	55
Total	**201**	**1,312**

Each owner entry lists every research card that resolves to that owner. A card link identifies the exported route. It does not imply that the implementation module itself is a supported public import path.

C.7.1 Config

komorebi_math.config. 4 research cards. Namespace counts: root 4. Cards: C.1A configure, C.1A get_settings, C.1A Settings, C.1A settings_context.

C.7.2 Certificates

komorebi_math.certificates. 4 research cards. Namespace counts: root 4. Cards: C.1A Certificate, C.1A ComputationResult, C.1A ConditionalResult, C.1A Exactness.

C.7.3 Compatibility

komorebi_math.compatibility. 14 research cards. Namespace counts: root 14. Cards: C.1A ApiCompatibilityReport, C.1A check_beta_api, C.1A check_public_api, C.1A compare_public_api, C.1A create_beta_api_manifest, C.1A create_public_api_manifest, C.1A deprecated, C.1A KomorebiDeprecationWarning, C.1A load_beta_api_manifest, C.1A load_public_api_manifest, C.1A PublicApiManifest, C.1A PublicApiSymbol, C.1A save_public_api_manifest, C.1A warn_deprecated.

C.7.4 Golden

komorebi_math.golden. 4 research cards. Namespace counts: root 4. Cards: C.1A BehavioralGoldenCaseResult, C.1A BehavioralGoldenReport, C.1A load_behavioral_golden_fixture, C.1A run_behavioral_golden_fixture.

C.7.5 Provenance

komorebi_math.provenance. 3 research cards. Namespace counts: root 3. Cards: C.1A ClaimStatus, C.1A describe, C.1A ProvenanceRecord.

C.7.6 Registry

komorebi_math.registry. 4 research cards. Namespace counts: root 4. Cards: C.1G feature, C.1G features, C.1G FeatureSpec, C.1G FeatureStatus.

C.7.7 Unified

komorebi_math.unified. 3 research cards. Namespace counts: root 3. Cards: C.1G StageSpec, C.1G UnifiedStage, C.1G UnifiedSystem.

C.7.8 Core

komorebi_math.core.algebra. 3 research cards. Namespace counts: root 3. Cards: C.1D AlgebraBasisResult, C.1D matrix_units, C.1D OperatorAlgebra.

komorebi_math.core.grammar. 4 research cards. Namespace counts: root 4. Cards: C.1D Arrow, C.1D OperatorGrammar, C.1D OperatorRelation, C.1D OperatorWord.

komorebi_math.core.graphs. 2 research cards. Namespace counts: root 2. Cards: C.1D SupportPreorder, C.1D TransferGraph.

komorebi_math.core.morphisms. 3 research cards. Namespace counts: root 3. Cards: C.1D OperatorMorphism, C.1D PacketMorphism, C.1D SeedMorphism.

komorebi_math.core.operators. 1 research card. Namespace counts: root 1. Cards: C.1D PacketOperator.

komorebi_math.core.packets. 2 research cards. Namespace counts: root 2. Cards: C.1D PacketCoordinates, C.1D PacketSystem.

komorebi_math.core.realization. 1 research card. Namespace counts: root 1. Cards: C.1D OperatorRealization.

komorebi_math.core.seeds. 7 research cards. Namespace counts: root 7. Cards: C.1D cyclic_span, C.1D independent_direct_sum_seed_rank, C.1D SeedSystem, C.1D semisimple_seed_rank, C.1D shared_direct_sum_seed_bounds, C.1D single_operator_seed_rank, C.1D tensor_seed_rank_upper_bound.

komorebi_math.core.transfer. 2 research cards. Namespace counts: root 2. Cards: C.1D block_from_paths, C.1D path_contributions.

C.7.9 Algorithms

komorebi_math.algorithms.compiler. 3 research cards. Namespace counts: root 3. Cards: C.1D compile_tree_budget, C.1D compile_tree_lagrangian, C.1D TreeNode.

komorebi_math.algorithms.discovery. 2 research cards. Namespace counts: root 2. Cards: C.1D discover_block_diagonal_low_rank, C.1D discover_packet_support.

komorebi_math.algorithms.ir. 1 research card. Namespace counts: root 1. Cards: C.1D PacketIR.

komorebi_math.algorithms.krylov. 1 research card. Namespace counts: root 1. Cards: C.1D conjugate_gradient.

komorebi_math.algorithms.layout. 1 research card. Namespace counts: root 1. Cards: C.1D PacketLayout.

komorebi_math.algorithms.low_rank. 3 research cards. Namespace counts: root 3. Cards: C.1D BlockDiagonalLowRankOperator, C.1D LowRankOperator, C.1D recompress_factors.

komorebi_math.algorithms.precision. 2 research cards. Namespace counts: root 2. Cards: C.1D assign_discrete_precisions, C.1D DTypeChoice.

komorebi_math.algorithms.scheduling. 2 research cards. Namespace counts: root 2. Cards: C.1D schedule_unlimited, C.1D Task.

komorebi_math.algorithms.structured. 4 research cards. Namespace counts: root 4. Cards: C.1D BlockDiagonalOperator, C.1D CirculantOperator, C.1D DenseOperator, C.1D WalshHadamardOperator.

C.7.10 Arithmetic

komorebi_math.arithmetic.domains. 1 research card. Namespace counts: root 1. Cards: C.1G TruncatedPadic.

komorebi_math.arithmetic.euler. 2 research cards. Namespace counts: root 2. Cards: C.1G EulerLocalCoordinates, C.1G signed_euler_number.

komorebi_math.arithmetic.hurwitz. 1 research card. Namespace counts: root 1. Cards: C.1G HurwitzSeries.

komorebi_math.arithmetic.mahler. 2 research cards. Namespace counts: root 2. Cards: C.1G affine_mahler_kernel, C.1G MahlerSeries.

komorebi_math.arithmetic.recurrence. 2 research cards. Namespace counts: root 2. Cards: C.1G fibonacci_recurrence, C.1G LinearRecurrence.

komorebi_math.arithmetic.standard_windows. 1 research card. Namespace counts: root 1. Cards: C.1G StandardWindow.

komorebi_math.arithmetic.valuation. 1 research card. Namespace counts: root 1. Cards: C.1G padic_valuation.

C.7.11 Sequences

komorebi_math.sequences.automatic. 1 research card. Namespace counts: root 1. Cards: C.1G AutomaticSequence.

komorebi_math.sequences.base. 1 research card. Namespace counts: root 1. Cards: C.1G Sequence.

komorebi_math.sequences.catalog. 6 research cards. Namespace counts: root 6. Cards: C.1G apery_sequence, C.1G fibonacci_sequence, C.1G get_sequence, C.1G motzkin_sequence, C.1G partition_sequence, C.1G thue_morse_sequence.

komorebi_math.sequences.compiler. 2 research cards. Namespace counts: root 2. Cards: C.1G compile_sequence, C.1G CompiledSequence.

komorebi_math.sequences.holonomic. 1 research card. Namespace counts: root 1. Cards: C.1G HolonomicRecurrence.

C.7.12 Analytic

komorebi_math.analytic.appell. 2 research cards. Namespace counts: root 2. Cards: C.1G appell_polynomial, C.1G theta_polynomial.

komorebi_math.analytic.cyclic. 1 research card. Namespace counts: root 1. Cards: C.1G cyclic_project_coefficients.

komorebi_math.analytic.reciprocal. 2 research cards. Namespace counts: root 2. Cards: C.1G reciprocal_coefficients, C.1G transfer_tangent.

komorebi_math.analytic.sections. 4 research cards. Namespace counts: root 4. Cards: C.1G CyclicSectionFamily, C.1G denominator, C.1G signed_section, C.1G transfer_section.

komorebi_math.analytic.zeros. 2 research cards. Namespace counts: root 2. Cards: C.1G CyclicDenominator, C.1G positive_zero_string.

C.7.13 Refinement

komorebi_math.refinement.crt. 2 research cards. Namespace counts: root 2. Cards: C.1G crt_many, C.1G crt_pair.

komorebi_math.refinement.defects. 1 research card. Namespace counts: root 1. Cards: C.1G LinearRefinementDefect.

komorebi_math.refinement.lattices. 1 research card. Namespace counts: root 1. Cards: C.1G LatticePacketData.

komorebi_math.refinement.residue. 2 research cards. Namespace counts: root 2. Cards: C.1G residue_analyze, C.1G residue_packet_system.

komorebi_math.refinement.smith. 1 research card. Namespace counts: root 1. Cards: C.1G SmithCongruenceProblem.

komorebi_math.refinement.towers. 3 research cards. Namespace counts: root 3. Cards: C.1G common_refinement, C.1G PacketRefinement, C.1G RefinementTower.

komorebi_math.refinement.weighted. 2 research cards. Namespace counts: root 2. Cards: C.1G WeightedTransferEdge, C.1G WeightedTransferGraph.

C.7.14 Coordinates

komorebi_math.coordinates.affine. 5 research cards. Namespace counts: coordinates 4, root 1. Cards: C.1C AffineCoordinateTransform, C.2C affine_basis_transform, C.2C AffineCoordinateTransform, C.2C BarycentricCoordinateSystem, C.2C translation_transform.

komorebi_math.coordinates.analysis_synthesis. 4 research cards. Namespace counts: coordinates 2, root 2. Cards: C.1C AnalysisSynthesisBlocks, C.1C AnalysisSynthesisSystem, C.2C AnalysisSynthesisBlocks, C.2C AnalysisSynthesisSystem.

komorebi_math.coordinates.basis. 16 research cards. Namespace counts: coordinates 11, root 5. Cards: C.1C basis_from_matrix, C.1C CoordinateAtlas, C.1C CoordinateSystem, C.1C FiniteBasis, C.1C standard_basis, C.2C AtlasPath, C.2C basis_from_matrix, C.2C CommutingDiagramCheck, C.2C CoordinateAtlas, C.2C CoordinateSystem, C.2C direct_sum_basis, C.2C FiniteBasis, C.2C permutation_transform, C.2C scaling_transform, C.2C standard_basis, C.2C tensor_product_basis.

komorebi_math.coordinates.budget. 3 research cards. Namespace counts: coordinates 2, root 1. Cards: C.1C CoordinateBudget, C.2C CoordinateBudget, C.2C DEFAULT_COORDINATE_BUDGET.

komorebi_math.coordinates.calculus. 11 research cards. Namespace counts: coordinates 10, root 1. Cards: C.1C PolynomialCoordinateOperator, C.2B affine_substitution_coordinate_operator, C.2B derivative_coordinate_operator, C.2B finite_difference_coordinate_operator, C.2B integral_coordinate_operator, C.2B multiplication_coordinate_operator, C.2B operator_commutator, C.2B polynomial_integral, C.2B polynomial_operator, C.2B PolynomialCoordinateOperator, C.2B transport_polynomial_operator.

komorebi_math.coordinates.classical. 44 research cards. Namespace counts: coordinates 42, root 2. Cards: C.1C classical_polynomial_catalog, C.1C get_polynomial_family, C.2B affine_polynomial, C.2B affine_substitution_transform, C.2B appell_polynomial, C.2B appell_polynomial_family, C.2B bernoulli_number, C.2B bernoulli_polynomial, C.2B bernoulli_polynomial_family, C.2B bernstein_basis, C.2B bernstein_polynomial, C.2B binomial_polynomial, C.2B binomial_polynomial_family, C.2B chebyshev_t_polynomial, C.2B chebyshev_t_polynomial_family, C.2B chebyshev_u_polynomial, C.2B chebyshev_u_polynomial_family, C.2B classical_polynomial_catalog, C.2B constant_polynomial, C.2B evaluation_transform, C.2B falling_factorial_polynomial, C.2B falling_factorial_polynomial_family, C.2B get_polynomial_family, C.2B hermite_physicists_polynomial, C.2B hermite_physicists_polynomial_family, C.2B hermite_probabilists_polynomial, C.2B hermite_probabilists_polynomial_family, C.2B interpolation_transform, C.2B lagrange_interpolation_basis, C.2B laguerre_polynomial, C.2B laguerre_polynomial_family, C.2B legendre_polynomial, C.2B legendre_polynomial_family, C.2B lucas_polynomial, C.2B lucas_polynomial_family, C.2B newton_interpolation_basis, C.2B operator_matrix_between_families, C.2B pell_polynomial, C.2B pell_polynomial_family, C.2B polynomial_compose_affine, C.2B polynomial_subtract, C.2B PolynomialFamilyCatalog, C.2B rising_factorial_polynomial, C.2B rising_factorial_polynomial_family.

komorebi_math.coordinates.combinatorial. 18 research cards. Namespace counts: coordinates 16, root 2. Cards: C.1C binomial_transform, C.1C forward_difference_transform, C.2A binomial_transform, C.2A divisor_zeta_transform, C.2A falling_factorial_to_monomial_transform, C.2A forward_difference_transform, C.2A lah_number, C.2A mobius_integer, C.2A monomial_to_falling_factorial_transform, C.2A monomial_to_rising_factorial_transform, C.2A newton_evaluation_transform, C.2A rising_factorial_to_monomial_transform, C.2A rising_to_falling_factorial_transform, C.2A stirling_first_signed, C.2A stirling_first_unsigned, C.2A stirling_second, C.2A subset_zeta_transform, C.2A transform_sequence.

komorebi_math.coordinates.exact. 19 research cards. Namespace counts: coordinates 19. Cards: C.2A as_matrix, C.2A as_vector, C.2A determinant, C.2A ExactLinearSystem, C.2A identity_matrix, C.2A inverse_matrix, C.2A matrix_add, C.2A matrix_from_columns, C.2A matrix_multiply, C.2A matrix_power, C.2A matrix_rank, C.2A matrix_shape, C.2A matrix_subtract, C.2A matrix_vector_multiply, C.2A nullspace, C.2A rref, C.2A solve_linear_system, C.2A transpose, C.2A zero_matrix.

komorebi_math.coordinates.families. 14 research cards. Namespace counts: coordinates 11, root 3. Cards: C.1C get_recurrence_model, C.1C recurrence_model_catalog, C.1C RecurrenceModel, C.2C custom_recurrence_model, C.2C fibonacci_recurrence_model, C.2C get_recurrence_model, C.2C jacobsthal_recurrence_model, C.2C lucas_recurrence_model, C.2C padovan_recurrence_model, C.2C pell_recurrence_model, C.2C recurrence_model_catalog, C.2C RecurrenceModel, C.2C sequence_coordinates_between_models, C.2C tribonacci_recurrence_model.

komorebi_math.coordinates.formal. 5 research cards. Namespace counts: coordinates 4, root 1. Cards: C.1C FormalCoordinateChange, C.2C compose_ordinary_series, C.2C formal_coordinate_from_iterable, C.2C FormalCoordinateChange, C.2C identity_formal_coordinate.

komorebi_math.coordinates.frame_algebra. 12 research cards. Namespace counts: coordinates 6, root 6. Cards: C.1C AnalysisSynthesisCoefficientBlocks, C.1C AnalysisSynthesisGauge, C.1C AnalysisSynthesisMap, C.1C CoefficientPartition, C.1C ExactAnalysisSynthesisMap, C.1C ExactAnalysisSynthesisSystem, C.2C AnalysisSynthesisCoefficientBlocks, C.2C AnalysisSynthesisGauge, C.2C AnalysisSynthesisMap, C.2C CoefficientPartition, C.2C ExactAnalysisSynthesisMap, C.2C ExactAnalysisSynthesisSystem.

komorebi_math.coordinates.modular. 3 research cards. Namespace counts: coordinates 2, root 1. Cards: C.1C FiniteFieldCoordinateTransform, C.2A FiniteFieldCoordinateTransform, C.2A reduce_exact_transform_mod_prime.

komorebi_math.coordinates.normalized. 4 research cards. Namespace counts: coordinates 3, root 1. Cards: C.1C normalization_change_transform, C.2A apply_lowering_polynomial, C.2A convert_normalized_coefficients, C.2A normalization_change_transform.

komorebi_math.coordinates.numeric. 9 research cards. Namespace counts: coordinates 7, root 2. Cards: C.1C discrete_fourier_transform, C.1C NumericCoordinateTransform, C.2C discrete_cosine_transform, C.2C discrete_fourier_transform, C.2C haar_wavelet_transform, C.2C modal_coordinate_system, C.2C ModalCoordinateSystem, C.2C NumericCoordinateTransform, C.2C walsh_hadamard_transform.

komorebi_math.coordinates.operators. 7 research cards. Namespace counts: coordinates 4, root 3. Cards: C.1C bezout_defect_identity, C.1C BezoutDefectIdentity, C.1C ShiftPolynomial, C.2C bezout_defect_identity, C.2C BezoutDefectIdentity, C.2C polynomial_extended_gcd, C.2C ShiftPolynomial.

komorebi_math.coordinates.packet. 10 research cards. Namespace counts: coordinates 9, root 1. Cards: C.1C residue_class_transform, C.2A chinese_remainder_order, C.2A chinese_remainder_transform, C.2A digit_reversal_order, C.2A digit_reversal_transform, C.2A residue_class_order, C.2A residue_class_transform, C.2A sorted_coordinate_transform, C.2A tensor_axis_permutation_order, C.2A tensor_axis_permutation_transform.

komorebi_math.coordinates.polynomials. 25 research cards. Namespace counts: coordinates 21, root 4. Cards: C.1C connection_transform, C.1C euler_to_fibonacci_transform, C.1C operator_change_of_coordinates, C.1C PolynomialFamily, C.2B connection_transform, C.2B derivative_operator_in_family, C.2B euler_polynomial, C.2B euler_polynomial_at_zero, C.2B euler_polynomial_family, C.2B euler_to_fibonacci_coefficient, C.2B euler_to_fibonacci_transform, C.2B fibonacci_companion_power, C.2B fibonacci_polynomial, C.2B fibonacci_polynomial_family, C.2B monomial_polynomial_family, C.2B monomial_to_fibonacci_coefficient, C.2B operator_change_of_coordinates, C.2B polynomial_add, C.2B polynomial_derivative, C.2B polynomial_evaluate, C.2B polynomial_multiply, C.2B polynomial_scale, C.2B polynomial_shift, C.2B PolynomialFamily, C.2B secant_euler_from_fibonacci_coordinates.

komorebi_math.coordinates.portable. 9 research cards. Namespace counts: coordinates 7, root 2. Cards: C.1C load_coordinate_object, C.1C save_coordinate_object, C.2C load_coordinate_object, C.2C load_coordinate_record, C.2C

load_transform, C.2C register_coordinate_codecs, C.2C save_coordinate_object, C.2C save_coordinate_record, C.2C save_transform.

komorebi_math.coordinates.realization. 15 research cards. Namespace counts: coordinates 9, root 6. Cards: C.1C intertwiner_space, C.1C IntertwinerSpace, C.1C LinearRealization, C.1C observability_matrix, C.1C recover_initial_state, C.1C StateRecovery, C.2C cyclic_krylov_matrix, C.2C intertwiner_space, C.2C IntertwinerSpace, C.2C LinearRealization, C.2C observability_matrix, C.2C realization_defect, C.2C recover_initial_state, C.2C similarity_from_cyclic_vectors, C.2C StateRecovery.

komorebi_math.coordinates.recurrence. 20 research cards. Namespace counts: coordinates 14, root 6. Cards: C.1C analyze_recurrence_coordinates, C.1C companion_matrix, C.1C coordinate_change_between_recurrences, C.1C euler_fibonacci_coordinates, C.1C RecurrenceCoordinateRecord, C.1C variation_of_constants_prefix, C.2C analyze_recurrence_coordinates, C.2C apply_recurrence_defect, C.2C companion_matrix, C.2C coordinate_change_between_recurrences, C.2C defect_green_weights, C.2C euler_fibonacci_coordinates, C.2C fibonacci_numbers, C.2C recurrence_analysis_transform, C.2C recurrence_polynomial, C.2C recurrence_synthesis_transform, C.2C RecurrenceCoordinateRecord, C.2C signed_secant_euler_numbers, C.2C synthesize_recurrence_coordinates, C.2C variation_of_constants_prefix.

komorebi_math.coordinates.state_space. 10 research cards. Namespace counts: coordinates 9, root 1. Cards: C.1C StateSpaceModel, C.2C certify_state_coordinate_change, C.2C controllability_basis, C.2C controllability_coordinate_transform, C.2C controllability_matrix, C.2C observability_block_matrix, C.2C observability_coordinate_transform, C.2C siso_state_space, C.2C StateSpaceCoordinateCertificate, C.2C StateSpaceModel.

komorebi_math.coordinates.tensor. 12 research cards. Namespace counts: coordinates 11, root 1. Cards: C.1C tensor_coordinate_transform, C.2A contragredient_transform, C.2A coordinate_pairing, C.2A direct_sum_transform, C.2A pairing_invariant, C.2A tensor_coordinate_transform, C.2A tensor_product_transform, C.2A transport_bilinear_form, C.2A transport_covector, C.2A transport_operator, C.2A transport_rectangular_operator, C.2A transport_tensor_components.

komorebi_math.coordinates.transform. 3 research cards. Namespace counts: coordinates 2, root 1. Cards: C.1C CoordinateTransform, C.2C CoordinateTransform, C.2C ExactCoordinateTransform.

C.7.15 Generating

komorebi_math.generating.adapters. 4 research cards. Namespace counts: generating 4. Cards: C.3A fir_taps_to_series, C.3A FIRSeriesAdapter, C.3A series_to_fir_adapter, C.3A series_to_fir_taps.

komorebi_math.generating.basis. 21 research cards. Namespace counts: coordinates 4, generating 13, root 4. Cards: C.1F factorial_power_basis, C.1F NormalizedBasis, C.1F ordinary_basis, C.1F WeightedMonomialBasis, C.2C exponential_basis, C.2C fibonacci_factorial_basis, C.2C NormalizedBasis, C.2C ordinary_basis, C.3A basis_from_descriptor, C.3A basis_from_values, C.3A BasisCertificate, C.3A BasisDescriptor, C.3A exponential_basis, C.3A factorial_power_basis, C.3A fibonacci_factorial_basis, C.3A NormalizedBasis, C.3A NormalizedMonomialBasis, C.3A ordinary_basis, C.3A pochhammer_basis, C.3A q_factorial_basis, C.3A WeightedMonomialBasis.

komorebi_math.generating.bell. 13 research cards. Namespace counts: generating 10, root 3. Cards: C.1F BellParityAutomaton, C.1F BellResidueAutomaton, C.1F generalized_bell_digit_reduction, C.3B bell_period_bound, C.3B BellDigitReduction, C.3B BellParityAutomaton, C.3B BellResidueAutomaton, C.3B certify_pointed_subindex_identity, C.3B generalized_bell_digit_reduction, C.3B generalized_bell_parity, C.3B pointed_subindex_polynomial, C.3B PointedSubindexCertificate, C.3B weighted_bell_digit_reduction.

komorebi_math.generating.budget. 3 research cards. Namespace counts: generating 2, root 1. Cards: C.1F GeneratingBudget, C.3A DEFAULT_GENERATING_BUDGET, C.3A GeneratingBudget.

komorebi_math.generating.cartier. 15 research cards. Namespace counts: generating 14, root 1. Cards: C.1F compile_rational_mask_automaton, C.3B AutomatonCertificate, C.3B cartier_degree_bound, C.3B CartierAutomaton, C.3B CartierCarryEquivalence, C.3B CartierLinearRepresentation, C.3B certify_cartier_carry_equivalence, C.3B compile_cartier_linear_representation, C.3B compile_rational_mask_automaton, C.3B finite_mask_carry_matrices, C.3B minimize_cartier_automaton, C.3B polynomial_cartier, C.3B polynomial_multiply_mod, C.3B polynomial_power_mod, C.3B rational_mask_coefficients_mod_prime.

komorebi_math.generating.closed_forms. 12 research cards. Namespace counts: generating 12. Cards: C.3A AlgebraicGFGuess, C.3A characteristic_closed_form, C.3A guess_algebraic_gf, C.3A guess_hypergeometric_ratio, C.3A

guess_linear_recurrence, C.3A guess_p_recursive, C.3A guess_quasipolynomial, C.3A HypergeometricGuess, C.3A LinearRecurrenceGuess, C.3A PRecursiveGuess, C.3A QuasiPolynomialGuess, C.3A rational_gf_from_recurrence.

komorebi_math.generating.congruences. 16 research cards. Namespace counts: generating 16. Cards: C.3B audit_apery_supercongruence, C.3B audit_factorial_power_packet_convolution, C.3B audit_generalized_bell_digit_sum, C.3B audit_generalized_lucas, C.3B audit_partition_lane, C.3B audit_q_lucas, C.3B audit_touchard, C.3B audit_weighted_generalized_bell_digit_sum, C.3B base_digit_sum, C.3B berlekamp_massey, C.3B difference_valuation_profile, C.3B mahler_coefficients, C.3B minimal_prefix_period, C.3B p_adic_valuation_fraction, C.3B scan_residue_lanes, C.3B search_decimation_relation.

komorebi_math.generating.cyclotomic. 6 research cards. Namespace counts: generating 6. Cards: C.3B cyclotomic_coboundary, C.3B CyclotomicCollapse, C.3B normalized_cyclotomic_expression, C.3B p_free_orbit, C.3B verify_cyclotomic_coboundary, C.3B verify_cyclotomic_exponent_relation.

komorebi_math.generating.digit_algebra. 6 research cards. Namespace counts: generating 6. Cards: C.3B audit_factorial_power_digit_algebra, C.3B base_digits, C.3B DigitAlgebraAudit, C.3B DigitKernel, C.3B factorial_power_digit_kernel, C.3B lift_digit_sequence.

komorebi_math.generating.domains. 9 research cards. Namespace counts: generating 9. Cards: C.3A CoefficientDomain, C.3A domain_from_descriptor, C.3A INTEGER_DOMAIN, C.3A IntegerDomain, C.3A PrimeFieldDomain, C.3A RATIONAL_DOMAIN, C.3A RationalDomain, C.3A ResidueRingDomain, C.3A TruncatedPadicDomain.

komorebi_math.generating.finite_series. 3 research cards. Namespace counts: generating 2, root 1. Cards: C.1F FiniteNormalizedSeries, C.3A FiniteNormalizedSeries, C.3A SeriesTransferCertificate.

komorebi_math.generating.functions. 13 research cards. Namespace counts: generating 11, root 2. Cards: C.1F CustomFunctionSpec, C.1F FunctionRegistry, C.3A algebraic_function, C.3A compose_functions, C.3A CustomFunctionSpec, C.3A euler_product_function, C.3A explicit_function, C.3A factorial_power_bell_function, C.3A FunctionRegistry, C.3A hypergeometric_function, C.3A linear_recurrence_function, C.3A rational_function, C.3A weighted_factorial_power_bell_function.

komorebi_math.generating.masks. 31 research cards. Namespace counts: generating 27, root 4. Cards: C.1F compile_finite_mask_carry_plan, C.1F FiniteMaskCarryPlan, C.1F mahler_mask_inverse, C.1F mahler_mask_product, C.3B analytic_mahler_product, C.3B AnalyticMaskApproximation, C.3B CarryLayerConvolution, C.3B certify_mahler_functional_equation, C.3B certify_rational_mask_algebraic_relation, C.3B compile_digit_cauchy_product, C.3B compile_finite_mask_carry_plan, C.3B DigitCauchyProductPlan, C.3B euler_product_collapse, C.3B EulerProductCollapse, C.3B factorial_power_convolution_layers, C.3B factorial_power_support_count, C.3B factorial_power_support_indices, C.3B FiniteMaskCarryPlan, C.3B first_frobenius_lift, C.3B frobenius_defect_mask, C.3B kummer_layer_distribution, C.3B KummerLayerDistribution, C.3B mahler_mask_inverse, C.3B mahler_mask_product, C.3B NormalizedMaskPlan, C.3B one_borrow_count, C.3B polynomial_mask_coboundary, C.3B PolynomialCoboundaryResult, C.3B RationalMaskAlgebraicCertificate, C.3B solve_polynomial_coboundary, C.3B zero_borrow_count.

komorebi_math.generating.monoid. 5 research cards. Namespace counts: generating 5. Cards: C.3A additive_series, C.3A dirichlet_convolution, C.3A FiniteMonoidSeries, C.3A multiplicative_series, C.3A prime_valuation_packets.

komorebi_math.generating.normalization. 6 research cards. Namespace counts: generating 6. Cards: C.3B CarryLinearCertificate, C.3B CarryLinearValuation, C.3B classify_carry_linear_valuation, C.3B digit_factorized_normalized_kernel, C.3B digit_unit, C.3B local_normalized_kernel.

komorebi_math.generating.padic_units. 9 research cards. Namespace counts: generating 8, root 1. Cards: C.1F PrimePowerKernelCompiler, C.3B binomial_valuation, C.3B borrow_count, C.3B factorial_valuation, C.3B integer_valuation, C.3B NormalizedKernelResidue, C.3B PrimePowerBinomial, C.3B PrimePowerKernelCompiler, C.3B PrimePowerUnitCompiler.

komorebi_math.generating.portable. 5 research cards. Namespace counts: generating 3, root 2. Cards: C.1F freeze_custom_function, C.1F FrozenGeneratingFunction, C.3A freeze_custom_function, C.3A FrozenGeneratingFunction, C.3A register_generating_codecs.

komorebi_math.generating.q_kummer. 9 research cards. Namespace counts: generating 8, root 1. Cards: C.1F q_binomial_valuation_decomposition, C.3B gaussian_binomial, C.3B multiplicative_order_mod_prime, C.3B q_binomial_support, C.3B q_binomial_valuation_decomposition, C.3B q_binomial_valuation_direct, C.3B q_factorial, C.3B q_integer, C.3B QKummerDecomposition.

komorebi_math.generating.sections. 5 research cards. Namespace counts: generating 5. Cards: C.3A audit_section_cycle, C.3A custom_exponential, C.3A custom_section, C.3A root_filter_value, C.3A SectionCycleAudit.

komorebi_math.generating.sequences. 12 research cards. Namespace counts: generating 12. Cards: C.3A apery_numbers, C.3A bell_numbers, C.3A bernoulli_numbers, C.3A catalan_numbers, C.3A central_binomial_numbers, C.3A fibonacci_numbers, C.3A generalized_bell_numbers, C.3A generalized_bell_polynomials, C.3A partition_numbers, C.3A signed_euler_numbers, C.3A weighted_generalized_bell_numbers, C.3A weighted_generalized_bell_polynomials.

komorebi_math.generating.series. 3 research cards. Namespace counts: generating 2, root 1. Cards: C.1F FormalSeries, C.3A FormalSeries, C.3A PacketIdentity.

C.7.16 Signals

komorebi_math.signals. 1 research card. Namespace counts: signals 1. Cards: C.4A status.

komorebi_math.signals.adaptive. 4 research cards. Namespace counts: signals 4. Cards: C.4B AdaptiveFilterResult, C.4B lms_filter, C.4B nlms_filter, C.4B rls_filter.

komorebi_math.signals.approximation. 5 research cards. Namespace counts: signals 5. Cards: C.4B estimate_positive_packet_1d, C.4B fft_lowpass_1d, C.4B fft_lowpass_2d, C.4B otsu_threshold, C.4B PacketEstimate1D.

komorebi_math.signals.convolution. 9 research cards. Namespace counts: signals 9. Cards: C.4A convolution_matrix, C.4A convolution_output_length, C.4A convolve_signal, C.4A finite_polyphase_blocks, C.4A finite_polyphase_filter_kernels, C.4A FinitePolyphaseKernel, C.4A polyphase_convolution, C.4A PolyphaseBlockMatrix, C.4A PolyphaseConvolution.

komorebi_math.signals.denoise. 10 research cards. Namespace counts: signals 10. Cards: C.4B denoising_risk_certificate, C.4B estimate_white_noise_sigma, C.4B haar_decompose, C.4B HaarDecomposition, C.4B median_absolute_deviation, C.4B sure_threshold, C.4B threshold_coefficients, C.4B universal_threshold, C.4B wavelet_denoise, C.4B WaveletDenoiseResult.

komorebi_math.signals.edge_recovery. 6 research cards. Namespace counts: signals 6. Cards: C.4B half_shift_distance, C.4B recover_vector_jumps, C.4B recover_vector_jumps_subgaussian, C.4B smooth_haar_coefficient_bound, C.4B step_haar_coefficient, C.4B VectorJumpRecoveryResult.

komorebi_math.signals.fft_convolution. 4 research cards. Namespace counts: signals 4. Cards: C.4A certified_overlap_add_convolve, C.4A fft_convolve, C.4A overlap_add_convolve, C.4A OverlapAddConvolver.

komorebi_math.signals.filterbanks. 12 research cards. Namespace counts: root 1, signals 11. Cards: C.1F PeriodicFilterBank, C.4B FilterBankReport, C.4B FiniteFilterBank, C.4B haar_analyze, C.4B haar_filter_bank, C.4B haar_matrix, C.4B haar_synthesize, C.4B HaarFilterBank, C.4B periodic_five_three_lifting, C.4B PeriodicFilterBank, C.4B PeriodicLiftingScheme, C.4B reconstruction_error.

komorebi_math.signals.filtering. 11 research cards. Namespace counts: signals 11. Cards: C.4A design_bandpass, C.4A design_bandstop, C.4A design_fir, C.4A design_highpass, C.4A design_lowpass, C.4A fir_filter, C.4A fir_frequency_response, C.4A FIRFilter, C.4A FrequencyResponse, C.4A stream_fir_filter, C.4A StreamingFIR.

komorebi_math.signals.nonlinear. 3 research cards. Namespace counts: signals 3. Cards: C.4B coefficient_packets, C.4B nonlinear_shift_filter, C.4B packet_product.

komorebi_math.signals.polyphase. 16 research cards. Namespace counts: root 2, signals 14. Cards: C.1F polyphase_analyze, C.1F PolyphaseSystem, C.4B lattice_polyphase_analyze, C.4B lattice_polyphase_synthesize, C.4B LatticePolyphaseCoordinates, C.4B mixed_radix_address, C.4B polyphase_analyze, C.4B polyphase_filter_kernels, C.4B polyphase_roundtrip_certificate, C.4B polyphase_synthesize, C.4B PolyphaseCoordinates, C.4B PolyphaseKernel, C.4B PolyphaseSystem, C.4B refinement_children, C.4B residue_project, C.4B split_mixed_radix_address.

komorebi_math.signals.recovery. 11 research cards. Namespace counts: root 1, signals 10. Cards: C.1F recover_separated_jumps, C.4B BreakpointBandResult, C.4B detect_piecewise_polynomial_breaks, C.4B finite_difference, C.4B haar_lipschitz_bound, C.4B haar_step_coefficient, C.4B JumpDetection, C.4B JumpRecoveryResult, C.4B recover_jumps_subgaussian, C.4B recover_separated_jumps, C.4B subgaussian_noise_bound.

komorebi_math.signals.recursive. 6 research cards. Namespace counts: signals 6. Cards: C.4A design_biquad, C.4A FilterOutput, C.4A lfilter, C.4A LinearFilter, C.4A stream_lfilter, C.4A StreamingLinearFilter.

komorebi_math.signals.resampling. 10 research cards. Namespace counts: signals 10. Cards: C.4A decimate, C.4A design_resample_filter, C.4A downsample, C.4A interpolate, C.4A RationalResamplingPlan, C.4A resample_poly, C.4A resample_poly_result, C.4A resampled_length, C.4A ResamplingResult, C.4A upsample.

komorebi_math.signals.singular_packets. 16 research cards. Namespace counts: root 2, signals 14. Cards: C.1F retained_packet_reconstruct, C.1F SingularPacket1D, C.4B difference_noise_bound, C.4B estimated_packet_reconstruct, C.4B overlap_matrix_error, C.4B overlap_partition_lp_error, C.4B retained_packet_reconstruct, C.4B retained_packet_reconstruction, C.4B RetainedPacketReconstruction, C.4B RetainedPacketResult, C.4B scalar_region_error, C.4B scalar_region_lp_error, C.4B SingularPacket1D, C.4B step_location_lp_error, C.4B TruncatedPowerPacket, C.4B TruncatedPowerTerm.

komorebi_math.signals.smith. 4 research cards. Namespace counts: signals 4. Cards: C.4B gamma_from_impedance, C.4B impedance_from_gamma, C.4B phase_mobius, C.4B smith_sensitivity.

komorebi_math.signals.spectral. 6 research cards. Namespace counts: signals 6. Cards: C.4A cross_spectrum, C.4A CrossSpectrum, C.4A parseval_certificate, C.4A periodogram, C.4A PowerSpectrum, C.4A welch_psd.

komorebi_math.signals.streaming. 3 research cards. Namespace counts: signals 3. Cards: C.4A stream_stft, C.4A StreamingSTFT, C.4A StreamingSTFTBatch.

komorebi_math.signals.time_frequency. 8 research cards. Namespace counts: signals 8. Cards: C.4A frame_signal, C.4A FrameBatch, C.4A istft, C.4A overlap_add, C.4A spectrogram, C.4A SpectrogramResult, C.4A stft, C.4A STFTResult.

komorebi_math.signals.wavelets. 11 research cards. Namespace counts: root 1, signals 10. Cards: C.1F HaarPacketTree, C.4B best_basis, C.4B BestBasisResult, C.4B entropy_cost, C.4B haar_packet_analyze, C.4B haar_packet_synthesize, C.4B HaarPacketTree, C.4B lp_cost, C.4B packet_energy, C.4B PrunedPacketCoefficients, C.4B shannon_entropy_cost.

komorebi_math.signals.windows. 6 research cards. Namespace counts: signals 6. Cards: C.4A canonical_dual_window, C.4A get_window, C.4A overlap_add_certificate, C.4A overlap_profile, C.4A window_metrics, C.4A WindowMetrics.

C.7.17 Nonlinear

komorebi_math.nonlinear. 2 research cards. Namespace counts: nonlinear 2. Cards: C.5B require, C.5A status.

komorebi_math.nonlinear.autodiff. 16 research cards. Namespace counts: nonlinear 8, root 8. Cards: C.1E autodiff_provider, C.1E automatic_derivative_provider, C.1E AutomaticDifferentiationProvider, C.1E available_ad_frameworks, C.1E available_autodiff_backends, C.1E DirectionalJVP, C.1E JaxDerivativeProvider, C.1E TorchDerivativeProvider, C.5A autodiff_provider, C.5A automatic_derivative_provider, C.5A AutomaticDifferentiationProvider, C.5A available_ad_frameworks, C.5A available_autodiff_backends, C.5A DirectionalJVP, C.5A JaxDerivativeProvider, C.5A TorchDerivativeProvider.

komorebi_math.nonlinear.composition. 11 research cards. Namespace counts: nonlinear 8, root 3. Cards: C.1E ComposedDerivativeProvider, C.1E faa_di_bruno, C.1E packet_faa_di_bruno, C.5A ComposedDerivativeProvider, C.5A faa_di_bruno, C.5A FaaDiBrunoResult, C.5A FaaDiBrunoTerm, C.5A labeled_composition_term_count, C.5A packet_faa_di_bruno, C.5A set_partitions, C.5A stirling_second.

komorebi_math.nonlinear.coordinates. 2 research cards. Namespace counts: nonlinear 1, root 1. Cards: C.1E NonlinearPacketMap, C.5A NonlinearPacketMap.

komorebi_math.nonlinear.correction. 10 research cards. Namespace counts: nonlinear 7, root 3. Cards: C.1E HilbertObstructionProjector, C.1E LyapunovSchmidtReduction, C.1E RightInverseCorrectionProblem, C.5A HilbertObstructionProjector, C.5A HilbertObstructionResult, C.5A LyapunovSchmidtDecomposition, C.5A LyapunovSchmidtPoint, C.5A LyapunovSchmidtReduction, C.5A RightInverseCorrectionProblem, C.5A RightInverseCorrectionResult.

komorebi_math.nonlinear.defects. 2 research cards. Namespace counts: nonlinear 1, root 1. Cards: C.1E NonlinearRefinementDefect, C.5A NonlinearRefinementDefect.

komorebi_math.nonlinear.derivatives. 9 research cards. Namespace counts: nonlinear 5, root 4. Cards: C.1E CallableDerivativeProvider, C.1E FiniteDifferenceDerivativeProvider, C.1E PolynomialDerivativeProvider, C.1E

SympyDerivativeProvider, C.5A CallableDerivativeProvider, C.5A DerivativeProvider, C.5A FiniteDifferenceDerivativeProvider, C.5A PolynomialDerivativeProvider, C.5A SympyDerivativeProvider.

komorebi_math.nonlinear.elimination. 5 research cards. Namespace counts: nonlinear 4, root 1. Cards: C.1E NonlinearSchurElimination, C.5A HiddenSolveResult, C.5A NonlinearSchurElimination, C.5A SchurDerivativeResult, C.5A SchurSecondDerivativeResult.

komorebi_math.nonlinear.execution. 22 research cards. Namespace counts: nonlinear 12, root 10. Cards: C.1E compile_packet_jet_plan, C.1E CuPyDeviceDerivativeProvider, C.1E CuPyPacketJetExecutor, C.1E CuPyPolynomialDerivativeProvider, C.1E execute_packet_jet_plan, C.1E execute_packet_jets, C.1E nonlinear_cupy_available, C.1E packet_jet_benchmark_contract, C.1E PacketJetBatchResult, C.1E PacketJetExecutionPlan, C.5B compile_packet_jet_plan, C.5B CuPyDeviceDerivativeProvider, C.5B CuPyPacketJetExecutor, C.5B CuPyPolynomialDerivativeProvider, C.5B execute_packet_jet_plan, C.5B execute_packet_jets, C.5B nonlinear_cupy_available, C.5B packet_jet_benchmark_contract, C.5B PacketJetBatchResult, C.5B PacketJetEvaluation, C.5B PacketJetExecutionPlan, C.5B PacketJetInputGroup.

komorebi_math.nonlinear.filtered. 16 research cards. Namespace counts: nonlinear 11, root 5. Cards: C.1E conditional_projective_limit_completion, C.1E FilteredCorrectionProblem, C.1E FilteredVectorSpace, C.1E FiniteFilteredCochainComplex, C.1E verify_finite_filtered_branch, C.5A conditional_projective_limit_completion, C.5A DepthObstructionResult, C.5A FilteredCorrectionProblem, C.5A FilteredSpectralSequenceResult, C.5A FilteredVectorSpace, C.5A FiniteFilteredBranchResult, C.5A FiniteFilteredCochainComplex, C.5A ProjectiveLimitRecord, C.5A SpectralSequenceEntry, C.5A SpectralSequencePage, C.5A verify_finite_filtered_branch.

komorebi_math.nonlinear.gpu. 12 research cards. Namespace counts: nonlinear 6, root 6. Cards: C.1E cupy_runtime_status, C.1E CuPyPacketJetSnapshotExecutor, C.1E CuPyRuntimeStatus, C.1E CuPySnapshotExecutor, C.1E CuPyValidationResult, C.1E validate_cupy_snapshot, C.5B cupy_runtime_status, C.5B CuPyPacketJetSnapshotExecutor, C.5B CuPyRuntimeStatus, C.5B CuPySnapshotExecutor, C.5B CuPyValidationResult, C.5B validate_cupy_snapshot.

komorebi_math.nonlinear.graded. 16 research cards. Namespace counts: nonlinear 11, root 5. Cards: C.1E divided_square_packets, C.1E FiniteAbelianGroup, C.1E GradedPacketOperation, C.1E higher_maurer_cartan_packets, C.1E maurer_cartan_packets, C.5A divided_square_packets, C.5A DividedSquareResult, C.5A FiniteAbelianGroup, C.5A GradedConvolutionResult, C.5A GradedConvolutionTerm, C.5A GradedPacketOperation, C.5A GradingCertificate, C.5A higher_maurer_cartan_packets, C.5A HigherMaurerCartanResult, C.5A maurer_cartan_packets, C.5A MaurerCartanResult.

komorebi_math.nonlinear.holonomy. 6 research cards. Namespace counts: nonlinear 4, root 2. Cards: C.1E TransportEdge, C.1E TransportGraph, C.5A FundamentalHolonomy, C.5A IntertwiningResult, C.5A TransportEdge, C.5A TransportGraph.

komorebi_math.nonlinear.jets. 11 research cards. Namespace counts: nonlinear 7, root 4. Cards: C.1E packet_jet_support, C.1E packet_taylor, C.1E PacketJet, C.1E PacketJetFamily, C.5B packet_jet_support, C.5B packet_taylor, C.5B PacketJet, C.5B PacketJetAddress, C.5B PacketJetFamily, C.5B PacketJetSupport, C.5B PacketTaylorResult.

komorebi_math.nonlinear.lifting. 13 research cards. Namespace counts: nonlinear 8, root 5. Cards: C.1E build_lift_tree, C.1E FiniteLiftTree, C.1E LinearLiftProblem, C.1E PolynomialLiftProblem, C.1E solve_mod_prime, C.5A build_lift_tree, C.5A FiniteLiftTree, C.5A LiftStepResult, C.5A LiftTreeNode, C.5A LinearLiftProblem, C.5A ModularLinearSolution, C.5A PolynomialLiftProblem, C.5A solve_mod_prime.

komorebi_math.nonlinear.obstruction. 4 research cards. Namespace counts: nonlinear 3, root 1. Cards: C.1E LinearObstructionProblem, C.5A LinearObstructionProblem, C.5A ObstructionResult, C.5A ObstructionSquare.

komorebi_math.nonlinear.profiling. 14 research cards. Namespace counts: nonlinear 7, root 7. Cards: C.1E estimate_packet_jet_complexity, C.1E PacketJetComplexityEstimate, C.1E PacketJetProfileReport, C.1E profile_operation, C.1E profile_packet_jet_runtime, C.1E RuntimeProfileSample, C.1E RuntimeStageProfile, C.5B estimate_packet_jet_complexity, C.5B PacketJetComplexityEstimate, C.5B PacketJetProfileReport, C.5B profile_operation, C.5B profile_packet_jet_runtime, C.5B RuntimeProfileSample, C.5B RuntimeStageProfile.

komorebi_math.nonlinear.snapshots. 5 research cards. Namespace counts: nonlinear 3, root 2. Cards: C.1E PacketJetSnapshot, C.1E snapshot_packet_jet, C.5B PacketJetCoefficient, C.5B PacketJetSnapshot, C.5B snapshot_packet_jet.

komorebi_math.nonlinear.sparse. 6 research cards. Namespace counts: nonlinear 3, root 3. Cards: C.1E SparsePolynomialDerivativeProvider, C.1E SparseSymmetricTensor, C.1E SparseTensorEntry, C.5B SparsePolynomialDerivativeProvider, C.5B SparseSymmetricTensor, C.5B SparseTensorEntry.

komorebi_math.nonlinear.streaming. 20 research cards. Namespace counts: nonlinear 10, root 10. Cards: C.1E capture_packet_jet_stream, C.1E load_packet_jet_snapshot_stream, C.1E open_packet_jet_snapshot_stream, C.1E PacketJetSnapshotStreamReader, C.1E PacketJetStreamChunkRecord, C.1E PacketJetStreamManifest, C.1E PacketJetStreamSelection, C.1E PacketJetStreamWriteResult, C.1E save_packet_jet_snapshot_stream, C.1E StreamedPacketJetEvaluation, C.5B capture_packet_jet_stream, C.5B load_packet_jet_snapshot_stream, C.5B open_packet_jet_snapshot_stream, C.5B PacketJetSnapshotStreamReader, C.5B PacketJetStreamChunkRecord, C.5B PacketJetStreamManifest, C.5B PacketJetStreamSelection, C.5B PacketJetStreamWriteResult, C.5B save_packet_jet_snapshot_stream, C.5B StreamedPacketJetEvaluation.

komorebi_math.nonlinear.transport. 9 research cards. Namespace counts: nonlinear 6, root 3. Cards: C.1E direct_packet_rotation, C.1E KatoTransport, C.1E MovingPacketSystem, C.5A direct_packet_rotation, C.5A DirectRotationResult, C.5A KatoTransport, C.5A MovingPacketSystem, C.5A PacketDerivativeResult, C.5A TransportRefinementResult.

komorebi_math.nonlinear.trees. 18 research cards. Namespace counts: nonlinear 13, root 5. Cards: C.1E majorant_convergence, C.1E OrderedRootedTree, C.1E packet_tree_reconstruction, C.1E PolynomialFixedPointProblem, C.1E quadratic_catalan_majorant, C.5B catalan_number, C.5B majorant_convergence, C.5B MajorantConvergence, C.5B ordered_rooted_trees, C.5B ordered_tree_count, C.5B ordered_trees_with_leaves, C.5B OrderedRootedTree, C.5B packet_tree_reconstruction, C.5B PacketTreeResult, C.5B PolynomialFixedPointProblem, C.5B quadratic_catalan_majorant, C.5B TreeExpansionResult, C.5B TreeTerm.

C.7.18 Integration

komorebi_math.integration.adapters. 6 research cards. Namespace counts: root 6. Cards: C.1D analysis_synthesis_integration_certificate, C.1D AtomicIntegratedDerivativeProvider, C.1D integrate_formal_series, C.1D integrate_polynomial_coordinates, C.1D polynomial_from_family_coordinates, C.1D polynomial_from_formal_series.

komorebi_math.integration.coordinates. 4 research cards. Namespace counts: root 4. Cards: C.1D coordinate_fundamental_theorem, C.1D coordinate_transport_identity, C.1D polynomial_integration_covector, C.1D PolynomialIntegrationCovector.

komorebi_math.integration.identities. 7 research cards. Namespace counts: root 7. Cards: C.1D affine_interval_change_of_variables, C.1D all_fubini_orders, C.1D fubini_identity, C.1D fundamental_theorem, C.1D IntegralIdentity, C.1D integration_by_parts, C.1D pushforward_identity.

komorebi_math.integration.measures. 8 research cards. Namespace counts: root 8. Cards: C.1D AtomicMeasure, C.1D ExactAffineMap, C.1D IntervalMeasure, C.1D Measure, C.1D product_measure, C.1D ProductMeasure, C.1D pushforward_measure, C.1D PushforwardMeasure.

komorebi_math.integration.polynomial. 1 research card. Namespace counts: root 1. Cards: C.1D ExactPolynomial.

komorebi_math.integration.quadrature. 9 research cards. Namespace counts: root 9. Cards: C.1D CompositeSimpson, C.1D DerivativeBound, C.1D ErrorGuarantee, C.1D IntegralResult, C.1D integrate, C.1D integrate_derivative_provider, C.1D integrate_polynomial_oriented, C.1D IntegrationError, C.1D polynomial_derivative_bound.

komorebi_math.integration.rules. 3 research cards. Namespace counts: root 3. Cards: C.1D ExactQuadratureRule, C.1D QuadratureExactness, C.1D QuadratureRule.

C.7.19 Dynamics

komorebi_math.dynamics.bayes. 1 research card. Namespace counts: root 1. Cards: C.1G BayesianUpdate.

komorebi_math.dynamics.feshbach. 1 research card. Namespace counts: root 1. Cards: C.1G FeshbachReduction.

komorebi_math.dynamics.fractional. 1 research card. Namespace counts: root 1. Cards: C.1G fractional_power.

komorebi_math.dynamics.markov. 1 research card. Namespace counts: root 1. Cards: C.1G MarkovLumping.

komorebi_math.dynamics.memory. 1 research card. Namespace counts: root 1. Cards: C.1G MemoryKernel.

komorebi_math.dynamics.semigroups. 1 research card. Namespace counts: root 1. Cards: C.1G MatrixSemigroup.

komorebi_math.dynamics.survival. 1 research card. Namespace counts: root 1. Cards: C.1G PhaseTypeSurvival.

C.7.20 Quantum

komorebi_math.quantum.channels. 1 research card. Namespace counts: root 1. Cards: C.1G QuantumChannel.

komorebi_math.quantum.circuits. 1 research card. Namespace counts: root 1. Cards: C.1G CircuitPacketExpansion.

komorebi_math.quantum.constraints. 1 research card. Namespace counts: root 1. Cards: C.1G constraint_closure.

komorebi_math.quantum.effective. 1 research card. Namespace counts: root 1. Cards: C.1G QuantumFeshbachReduction.

komorebi_math.quantum.error_correction. 1 research card. Namespace counts: root 1. Cards: C.1G QuantumCode.

komorebi_math.quantum.euclidean. 1 research card. Namespace counts: root 1. Cards: C.1G EuclideanTransfer.

komorebi_math.quantum.leakage. 1 research card. Namespace counts: root 1. Cards: C.1G fixed_packet_leakage.

komorebi_math.quantum.lindblad. 1 research card. Namespace counts: root 1. Cards: C.1G LindbladGenerator.

komorebi_math.quantum.seeds. 1 research card. Namespace counts: root 1. Cards: C.1G QuantumSeedSystem.

komorebi_math.quantum.spectral. 2 research cards. Namespace counts: root 2. Cards: C.1G periodic_laplacian, C.1G spectral_dimension.

komorebi_math.quantum.symmetry. 1 research card. Namespace counts: root 1. Cards: C.1G cyclic_symmetry_projectors.

C.7.21 Deformation

komorebi_math.deformation.companions. 2 research cards. Namespace counts: root 2. Cards: C.1G finite_frobenius_separator, C.1G FrobeniusSpine.

komorebi_math.deformation.complexes. 1 research card. Namespace counts: root 1. Cards: C.1G FiniteCochainComplex.

komorebi_math.deformation.forests. 1 research card. Namespace counts: root 1. Cards: C.1G FiniteLiftForest.

komorebi_math.deformation.support. 1 research card. Namespace counts: root 1. Cards: C.1G PresentedModule.

komorebi_math.deformation.visibility. 1 research card. Namespace counts: root 1. Cards: C.1G VisibilityTree.

C.7.22 Langlands

komorebi_math.langlands.completion.gates. 4 research cards. Namespace counts: root 4. Cards: C.1G AutomorphicCompletionReport, C.1G CompatiblePropagationReport, C.1G CompletionGate, C.1G GateStatus.

komorebi_math.langlands.finite_image.characters. 2 research cards. Namespace counts: root 2. Cards: C.1G InducedRepresentation, C.1G LinearCharacter.

komorebi_math.langlands.finite_image.clifford. 2 research cards. Namespace counts: root 2. Cards: C.1G CliffordStep, C.1G CliffordTower.

komorebi_math.langlands.finite_image.groups. 2 research cards. Namespace counts: root 2. Cards: C.1G cyclic_group, C.1G FiniteGroup.

komorebi_math.langlands.finite_image.mackey. 1 research card. Namespace counts: root 1. Cards: C.1G mackey_tensor_packets.

komorebi_math.langlands.finite_image.orbits. 1 research card. Namespace counts: root 1. Cards: C.1G MonomialAction.

komorebi_math.langlands.finite_image.plans. 1 research card. Namespace counts: root 1. Cards: C.1G AutomorphicInductionPlan.

komorebi_math.langlands.global_.dyadic. 1 research card. Namespace counts: root 1. Cards: C.1G dyadic_sign_diagnostic.

komorebi_math.langlands.global_.hecke. 2 research cards. Namespace counts: root 2. Cards: C.1G FiniteHeckePackets, C.1G SupportComparison.

komorebi_math.langlands.global_.patching. 1 research card. Namespace counts: root 1. Cards: C.1G PatchingSupportReport.

komorebi_math.langlands.local.envelopes. 1 research card. Namespace counts: root 1. Cards: C.1G ProjectiveIntertwinerEnvelope.

komorebi_math.langlands.local.finite_fields. 1 research card. Namespace counts: root 1. Cards: C.1G FiniteField.

komorebi_math.langlands.local.gauss. 1 research card. Namespace counts: root 1. Cards: C.1G gauss_sum.

komorebi_math.langlands.local.heisenberg. 1 research card. Namespace counts: root 1. Cards: C.1G HeisenbergModel.

komorebi_math.langlands.local.symplectic. 2 research cards. Namespace counts: root 2. Cards: C.1G AlternatingForm, C.1G QuadraticRefinement.

komorebi_math.langlands.local.tame. 2 research cards. Namespace counts: root 2. Cards: C.1G FrobeniusOrbit, C.1G TameWeilPacket.

komorebi_math.langlands.ramification.towers. 3 research cards. Namespace counts: root 3. Cards: C.1G ProjectiveMultiplicityPacket, C.1G RamificationCliffordTower, C.1G RamificationStage.

C.7.23 Expression

komorebi_math.expression.certification. 7 research cards. Namespace counts: root 7. Cards: C.1B compose_certificates, C.1B exact_internal_certificate, C.1B exactness_strength, C.1B ExpressionBinding, C.1B NormalForm, C.1B RewriteStep, C.1B weakest_exactness.

komorebi_math.expression.engine. 15 research cards. Namespace counts: root 15. Cards: C.1B check_expression, C.1B CheckedExpression, C.1B compile_expression, C.1B EquivalenceResult, C.1B equivalent, C.1B evaluate_expression, C.1B exact_binding, C.1B execute_plan, C.1B ExpressionPlan, C.1B ExpressionResult, C.1B normal_form_digest, C.1B normalize_expression, C.1B PlanInstruction, C.1B SimplificationResult, C.1B simplify_expression.

komorebi_math.expression.model. 28 research cards. Namespace counts: root 28. Cards: C.1B add, C.1B Apply, C.1B apply, C.1B Compose, C.1B compose, C.1B exact_map, C.1B exact_value, C.1B ExactMapLiteral, C.1B ExactValueLiteral, C.1B Expression, C.1B ExpressionBudget, C.1B ExpressionStats, C.1B identity, C.1B IdentityMap, C.1B Let, C.1B let, C.1B LinearMapType, C.1B PolynomialCoordinateSpace, C.1B RATIONAL_SPACE, C.1B RationalSpace, C.1B Scale, C.1B scale, C.1B Sum, C.1B Symbol, C.1B symbol, C.1B then, C.1B zero_map, C.1B ZeroMap.

komorebi_math.expression.planning. 5 research cards. Namespace counts: root 5. Cards: C.1B matrix_chain_multiply, C.1B matrix_chain_parenthesization, C.1B matrix_chain_plan, C.1B MatrixChainPlan, C.1B MatrixChainTree.

komorebi_math.expression.polynomial. 15 research cards. Namespace counts: root 15. Cards: C.1B affine_substitution, C.1B antiderivative, C.1B boundary_functional, C.1B constant_injection, C.1B coordinate_change, C.1B derivative, C.1B evaluation, C.1B finite_difference, C.1B interval_integration, C.1B PolynomialPrimitive, C.1B primitive_certificate, C.1B primitive_matrix_equal, C.1B PrimitiveKind, C.1B replay, C.1B replay_matrix.

komorebi_math.expression.portable. 7 research cards. Namespace counts: root 7. Cards: C.1B expression_digest, C.1B expression_from_dict, C.1B expression_from_json, C.1B expression_to_dict, C.1B expression_to_json, C.1B type_from_dict, C.1B type_to_dict.

C.7.24 Export

komorebi_math.export.latex. 10 research cards. Namespace counts: export 6, root 4. Cards: C.1F available_latex_engines, C.1F compile_latex, C.1F LatexCompileOptions, C.1F LatexEngine, C.6 available_latex_engines, C.6 compile_latex, C.6 LatexCompilation, C.6 LatexCompileOptions, C.6 LatexEngine, C.6 resolve_latex_engine.

komorebi_math.export.model. 14 research cards. Namespace counts: export 10, root 4. Cards: C.1F DocumentMetadata, C.1F Equation, C.1F MathDocument, C.1F Table, C.6 CodeBlock, C.6 DocumentMetadata, C.6 Equation, C.6 Figure, C.6 Heading, C.6 ListBlock, C.6 MathDocument, C.6 Paragraph, C.6 RawLatex, C.6 Table.

komorebi_math.export.persistence. 24 research cards. Namespace counts: export 13, root 11. Cards: C.1F dumps_portable, C.1F load_portable, C.1F loads_portable, C.1F portable_codecs, C.1F portable_digest, C.1F portable_migrations, C.1F PortableCodec, C.1F PortableMigration, C.1F register_portable_codec, C.1F register_portable_

migration, C.1F save_portable, C.6 dumps_portable, C.6 from_portable_data, C.6 load_portable, C.6 loads_portable, C.6 portable_codecs, C.6 portable_digest, C.6 portable_migrations, C.6 PortableCodec, C.6 PortableMigration, C.6 register_portable_codec, C.6 register_portable_migration, C.6 save_portable, C.6 to_portable_data.

komorebi_math.export.renderers. 10 research cards. Namespace counts: export 8, root 2. Cards: C.1F LatexRenderOptions, C.1F render_latex, C.6 HtmlRenderOptions, C.6 latex_escape, C.6 latex_label, C.6 LatexRenderOptions, C.6 render_html, C.6 render_latex, C.6 render_markdown, C.6 render_text.

komorebi_math.export.report. 5 research cards. Namespace counts: export 3, root 2. Cards: C.1F document_from_data, C.1F sequence_document, C.6 certificate_document, C.6 document_from_data, C.6 sequence_document.

komorebi_math.export.serialization. 8 research cards. Namespace counts: export 6, root 2. Cards: C.1F from_serializable, C.1F to_serializable, C.6 export_adapters, C.6 Exportable, C.6 from_serializable, C.6 register_export_adapter, C.6 table_rows, C.6 to_serializable.

komorebi_math.export.writers. 19 research cards. Namespace counts: export 10, root 9. Cards: C.1F available_export_formats, C.1F export_bundle, C.1F export_data, C.1F export_document, C.1F export_many, C.1F ExportBundleResult, C.1F ExportFormat, C.1F ExportOptions, C.1F ExportResult, C.6 available_export_formats, C.6 export_bundle, C.6 export_data, C.6 export_document, C.6 export_many, C.6 ExportBundleResult, C.6 ExportFormat, C.6 ExportOptions, C.6 ExportResult, C.6 infer_export_format.

C.7.25 External Python and typing owners

builtins. 29 research cards. Namespace counts: coordinates 5, export 2, nonlinear 6, root 15, signals 1. Cards: C.1A **version**, C.1A API_STABILITY_LEVEL, C.1A BEHAVIORAL_GOLDEN_SCHEMA, C.1A BEHAVIORAL_GOLDEN_SCHEMA_VERSION, C.1A BETA_API_STABILITY_LEVEL, C.1A BETA_PUBLIC_NAMESPACES, C.1A EXPRESSION_NODE_VERSION, C.1A EXPRESSION_SCHEMA, C.1A EXPRESSION_SCHEMA_VERSION, C.1A EXPRESSION_TYPE_VERSION, C.1A PACKET_JET_CHUNK_SCHEMA, C.1A PACKET_JET_CHUNK_SCHEMA_VERSION, C.1A PACKET_JET_STREAM_SCHEMA, C.1A PACKET_JET_STREAM_SCHEMA_VERSION, C.1A STAGES, C.2C Matrix, C.2C ModularMatrix, C.2C ModularVector, C.2C Polynomial, C.2C Vector, C.6 PORTABLE_SCHEMA, C.6 PORTABLE_SCHEMA_VERSION, C.5B FEATURE_KEY, C.5B PACKET_JET_CHUNK_SCHEMA, C.5B PACKET_JET_CHUNK_SCHEMA_VERSION, C.5B PACKET_JET_STREAM_SCHEMA, C.5B PACKET_JET_STREAM_SCHEMA_VERSION, C.5A Partition, C.4A FEATURE_KEY.

collections.abc. 3 research cards. Namespace counts: nonlinear 2, root 1. Cards: C.1E MultilinearOperation, C.5A DirectionalDerivative, C.5B MultilinearOperation.

pathlib. 2 research cards. Namespace counts: root 2. Cards: C.1G DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE, C.1G DEFAULT_BETA_API_MANIFEST.

types. 5 research cards. Namespace counts: coordinates 1, nonlinear 1, root 2, signals 1. Cards: C.1A CoordinateSpace, C.1A ExpressionType, C.2C Scalar, C.5B PacketLabel, C.4A PacketPath.

typing. 16 research cards. Namespace counts: coordinates 2, signals 14. Cards: C.2C RecurrenceLike, C.2C Variance, C.4A AdaptiveMethod, C.4A BiquadKind, C.4A BoundaryMode, C.4A ConvolutionMode, C.4A DetrendMode, C.4A FIRKind, C.4A FIRMode, C.4A SpectralAverage, C.4A SpectralScaling, C.4A SpectrogramScaling, C.4A ThresholdMode, C.4A ThresholdRule, C.4A WindowName, C.4A WindowSpec.

C.8 Alphabetical research exported-name index

The research manifest contains 1,093 distinct exported names across 1,312 namespace and name pairs. A name can occur in as many as three research namespaces. The 217 repeated-name groups below retain every route instead of collapsing a domain export into its root facade.

Quantity	Count
Distinct research exported names	1,093
Research namespace and name pairs	1,312
Names present in more than one research namespace	217
Maximum research namespaces for one name	3

C.8.1 Names beginning with A

`AdaptiveFilterResult`. 1 research route: signals. `AdaptiveMethod`. 1 research route: signals. `add`. 1 research route: root. `additive_series`. 1 research route: generating. `affine_basis_transform`. 1 research route: coordinates. `affine_interval_change_of_variables`. 1 research route: root. `affine_mahler_kernel`. 1 research route: root. `affine_polynomial`. 1 research route: coordinates. `affine_substitution`. 1 research route: root. `affine_substitution_coordinate_operator`. 1 research route: coordinates. `affine_substitution_transform`. 1 research route: coordinates. `AffineCoordinateTransform`. 2 research routes: root, coordinates. `AlgebraBasisResult`. 1 research route: root. `algebraic_function`. 1 research route: generating. `AlgebraicGFGuess`. 1 research route: generating. `all_fubini_orders`. 1 research route: root. `AlternatingForm`. 1 research route: root. `analysis_synthesis_integration_certificate`. 1 research route: root. `AnalysisSynthesisBlocks`. 2 research routes: root, coordinates. `AnalysisSynthesisCoefficientBlocks`. 2 research routes: root, coordinates. `AnalysisSynthesisGauge`. 2 research routes: root, coordinates. `AnalysisSynthesisMap`. 2 research routes: root, coordinates. `AnalysisSynthesisSystem`. 2 research routes: root, coordinates. `analytic_mahler_product`. 1 research route: generating. `AnalyticMaskApproximation`. 1 research route: generating. `analyze_recurrence_coordinates`. 2 research routes: root, coordinates. `antiderivative`. 1 research route: root. `apery_numbers`. 1 research route: generating. `apery_sequence`. 1 research route: root. `API_STABILITY_LEVEL`. 1 research route: root. `ApiCompatibilityReport`. 1 research route: root. `appell_polynomial`. 2 research routes: root, coordinates. `appell_polynomial_family`. 1 research route: coordinates. `Apply`. 1 research route: root. `apply`. 1 research route: root. `apply_lowering_polynomial`. 1 research route: coordinates. `apply_recurrence_defect`. 1 research route: coordinates. `Arrow`. 1 research route: root. `as_matrix`. 1 research route: coordinates. `as_vector`. 1 research route: coordinates. `assign_discrete_precisions`. 1 research route: root. `AtlasPath`. 1 research route: coordinates. `AtomicIntegratedDerivativeProvider`. 1 research route: root. `AtomicMeasure`. 1 research route: root. `audit_apery_supercongruence`. 1 research route: generating. `audit_factorial_power_digit_algebra`. 1 research route: generating. `audit_factorial_power_packet_convolution`. 1 research route: generating. `audit_generalized_bell_digit_sum`. 1 research route: generating. `audit_generalized_lucas`. 1 research route: generating. `audit_partition_lane`. 1 research route: generating. `audit_q_lucas`. 1 research route: generating. `audit_section_cycle`. 1 research route: generating. `audit_touchard`. 1 research route: generating. `audit_weighted_generalized_bell_digit_sum`. 1 research route: generating. `autodiff_provider`. 2 research routes: root, nonlinear. `automatic_derivative_provider`. 2 research routes: root, nonlinear. `AutomaticDifferentiationProvider`. 2 research routes: root, nonlinear. `AutomaticSequence`. 1 research route: root. `AutomatonCertificate`. 1 research route: generating. `AutomorphicCompletionReport`. 1 research route: root. `AutomorphicInductionPlan`. 1 research route: root. `available_ad_frameworks`. 2 research routes: root, nonlinear. `available_autodiff_backends`. 2 research routes: root, nonlinear. `available_export_formats`. 2 research routes: root, export. `available_latex_engines`. 2 research routes: root, export.

C.8.2 Names beginning with B

`BarycentricCoordinateSystem`. 1 research route: coordinates. `base_digit_sum`. 1 research route: generating. `base_digits`. 1 research route: generating. `basis_from_descriptor`. 1 research route: generating. `basis_from_matrix`. 2 research routes: root, coordinates. `basis_from_values`. 1 research route: generating. `BasisCertificate`. 1 research route: generating. `BasisDescriptor`. 1 research route: generating. `BayesianUpdate`. 1 research route: root. `BEHAVIORAL_GOLDEN_SCHEMA`. 1 research route: root. `BEHAVIORAL_GOLDEN_SCHEMA_VERSION`. 1 research route: root. `BehavioralGoldenCaseResult`. 1 research route: root. `BehavioralGoldenReport`. 1 research route: root. `bell_numbers`. 1 research route: generating. `bell_period_bound`. 1 research route: generating. `BellDigitReduction`. 1 research route: generating. `BellParityAutomaton`. 2 research routes: root, generating. `BellResidueAutomaton`. 2 research routes: root, generating. `berlekamp_massey`. 1 research route: generating. `bernoulli_number`. 1 research route: coordinates. `bernoulli_numbers`. 1 research route: generating. `bernoulli_polynomial`. 1 research route: coordinates. `bernoulli_polynomial_family`. 1 research route: coordinates. `bernstein_basis`. 1 research route: coordinates. `bernstein_polynomial`. 1 research route: coordinates. `best_basis`. 1 research route: signals. `BestBasisResult`. 1 research route: signals. `BETA_API_STABILITY_LEVEL`. 1 research route: root. `BETA_PUBLIC_NAMESPACES`. 1 research route: root. `bezout_defect_identity`. 2 research routes: root, coordinates. `BezoutDefectIdentity`. 2 research routes: root, coordinates. `binomial_polynomial`. 1 research route: coordinates. `binomial_polynomial_family`. 1 research route: coordinates. `binomial_transform`. 2 research routes: root, coordinates. `binomial_valuation`. 1 research route: generating. `BiquadKind`. 1 research route: signals. `block_from_paths`. 1 research route: root. `BlockDiagonalLowRankOperator`. 1 research route: root. `BlockDiagonalOperator`. 1 research route: root. `borrow_count`. 1 research route: generating. `boundary_functional`. 1 research route: root. `BoundaryMode`. 1 research route: signals. `BreakpointBandResult`. 1 research route: signals. `build_lift_tree`. 2 research routes: root, nonlinear.

C.8.3 Names beginning with C

`CallableDerivativeProvider`. 2 research routes: root, nonlinear. `canonical_dual_window`. 1 research route: signals. `capture_packet_jet_stream`. 2 research routes: root, nonlinear. dinates. `cyclic_project_coefficients`. 1 research route: root. `cyclic_span`. 1 research route: root. `cyclic_symmetry_projectors`. 1 research route: root. `CyclicDenominator`. 1 research route: root. `CyclicSectionFamily`. 1 research route: root. `cyclotomic_coboundary`. 1 research route: generating. `CyclotomicCollapse`. 1 research route: generating.

C.8.4 Names beginning with D

`decimate`. 1 research route: signals. `DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE`. 1 research route: root. `DEFAULT_BETA_API_MANIFEST`. 1 research route: root. `DEFAULT_COORDINATE_BUDGET`. 1 research route: coordinates. `DEFAULT_GENERATING_BUDGET`. 1 research route: generating. `defect_green_weights`. 1 research route: coordinates. `denoising_risk_certificate`. 1 research route: signals. `denominator`. 1 research route: root. `DenseOperator`. 1 research route: root. `deprecated`. 1 research route: root. `DepthObstructionResult`. 1 research route: nonlinear. `derivative`. 1 research route: root. `derivative_coordinate_operator`. 1 research route: coordinates. `derivative_operator_in_family`. 1 research route: coordinates. `DerivativeBound`. 1 research route: root. `DerivativeProvider`. 1 research route: nonlinear. `describe`. 1 research route: root. `design_bandpass`. 1 research route: signals. `design_bandstop`. 1 research route: signals. `design_biquad`. 1 research route: signals. `design_fir`. 1 research route: signals. `design_highpass`. 1 research route: signals. `design_lowpass`. 1 research route: signals. `design_resample_filter`. 1 research route: signals. `detect_piecewise_polynomial_breaks`. 1 research route: signals. `determinant`. 1 research route: coordinates. `DetrendMode`. 1 research route: signals. `difference_noise_bound`. 1 research route: signals. `difference_valuation_profile`. 1 research route: generating. `digit_factorized_normalized_kernel`. 1 research route: generating. `digit_reversal_order`. 1 research route: coordinates. `digit_reversal_transform`. 1 research route: coordinates. `digit_unit`. 1 research route: generating. `DigitAlgebraAudit`. 1 research route: generating. `DigitCauchyProductPlan`. 1 research route: generating. `DigitKernel`. 1 research route: generating. `direct_packet_rotation`. 2 research routes: root, nonlinear. `direct_sum_basis`. 1 research route: coordinates. `direct_sum_transform`. 1 research route: coordinates. `DirectionalDerivative`. 1 research route: nonlinear. `DirectionalJVP`. 2 research routes: root, nonlinear. `DirectRotationResult`. 1 research route: nonlinear. `dirichlet_convolution`. 1 research route: generating. `discover_block_diagonal_low_rank`. 1 research route: root. `discover_packet_support`. 1 research route: root. `discrete_cosine_transform`. 1 research route: coordinates. `discrete_fourier_transform`. 2 research routes: root, coordinates. `divided_square_packets`. 2 research routes: root, nonlinear. `DividedSquareResult`. 1 research route: nonlinear. `divisor_zeta_transform`. 1 research route: coordinates. `document_from_data`. 2 research routes: root, export. `DocumentMetadata`. 2 research routes: root, export. `domain_from_descriptor`. 1 research route: generating. `downsample`. 1 research route: signals. `DTypeChoice`. 1 research route: root. `dumps_portable`. 2 research routes: root, export. `dyadic_sign_diagnostic`. 1 research route: root.

C.8.5 Names beginning with E

`entropy_cost`. 1 research route: signals. `Equation`. 2 research routes: root, export. `EquivalenceResult`. 1 research route: root. `equivalent`. 1 research route: root. `ErrorGuarantee`. 1 research route: root. `estimate_packet_jet_complexity`. 2 research routes: root, nonlinear. `estimate_positive_packet_1d`. 1 research route: signals. `estimate_white_noise_sigma`. 1 research route: signals. `estimated_packet_reconstruct`. 1 research route: signals. `EuclideanTransfer`. 1 research route: root. `euler_fibonacci_coordinates`. 2 research routes: root, coordinates. `euler_polynomial`. 1 research route: coordinates. `euler_polynomial_at_zero`. 1 research route: coordinates. `euler_polynomial_family`. 1 research route: coordinates. `euler_product_collapse`. 1 research route: generating. `euler_product_function`. 1 research route: generating. `euler_to_fibonacci_coefficient`. 1 research route: coordinates. `euler_to_fibonacci_transform`. 2 research routes: root, coordinates. `EulerLocalCoordinates`. 1 research route: root. `EulerProductCollapse`. 1 research route: generating. `evaluate_expression`. 1 research route: root. `evaluation`. 1 research route: root. `evaluation_transform`. 1 research route: coordinates. `exact_binding`. 1 research route: root. `exact_internal_certificate`. 1 research route: root. `exact_map`. 1 research route: root. `exact_value`. 1 research route: root. `ExactAffineMap`. 1 research route: root. `ExactAnalysisSynthesisMap`. 2 research routes: root, coordinates. `ExactAnalysisSynthesisSystem`. 2 research routes: root, coordinates. `ExactCoordinateTransform`. 1 research route: coordinates. `ExactLinearSystem`. 1 research route: coordinates. `ExactMapLiteral`. 1 research route: root. `Exactness`. 1 research route: root. `exactness_strength`. 1 research route: root. `ExactPolynomial`. 1 research route: root. `ExactQuadratureRule`. 1 research route: root. `ExactValueLiteral`. 1 research route: root. `execute_packet_jet_plan`. 2 research routes: root, nonlinear. `execute_packet_jets`. 2 research routes: root, nonlinear. `execute_plan`. 1 research route: root. `explicit_function`. 1 research route: generating. `exponential_basis`. 2 research routes: coordinates, generating. `export_adapters`. 1 research route: export. `export_bundle`. 2 research routes: root, export. `export_data`. 2 research routes: root, export. `export_document`. 2 research routes: root, export. `export_many`. 2 research routes: root, export. `Exportable`. 1 research route: export. `ExportBundleResult`. 2 research routes:

root, export. `ExportFormat`. 2 research routes: root, export. `ExportOptions`. 2 research routes: root, export. `ExportResult`. 2 research routes: root, export. `Expression`. 1 research route: root. `expression_digest`. 1 research route: root. `expression_from_dict`. 1 research route: root. `expression_from_json`. 1 research route: root. `EXPRESSION_NODE_VERSION`. 1 research route: root. `EXPRESSION_SCHEMA`. 1 research route: root. `EXPRESSION_SCHEMA_VERSION`. 1 research route: root. `expression_to_dict`. 1 research route: root. `expression_to_json`. 1 research route: root. `EXPRESSION_TYPE_VERSION`. 1 research route: root. `ExpressionBinding`. 1 research route: root. `ExpressionBudget`. 1 research route: root. `ExpressionPlan`. 1 research route: root. `ExpressionResult`. 1 research route: root. `ExpressionStats`. 1 research route: root. `ExpressionType`. 1 research route: root.

C.8.6 Names beginning with F

`faa_di_bruno`. 2 research routes: root, nonlinear. `FaaDiBrunoResult`. 1 research route: nonlinear. `FaaDiBrunoTerm`. 1 research route: nonlinear. `factorial_power_basis`. 2 research routes: root, generating. `factorial_power_bell_function`. 1 research route: generating. `factorial_power_convolution_layers`. 1 research route: generating. `factorial_power_digit_kernel`. 1 research route: generating. `factorial_power_support_count`. 1 research route: generating. `factorial_power_support_indices`. 1 research route: generating. `factorial_valuation`. 1 research route: generating. `falling_factorial_polynomial`. 1 research route: coordinates. `falling_factorial_polynomial_family`. 1 research route: coordinates. `falling_factorial_to_monomial_transform`. 1 research route: coordinates. `feature`. 1 research route: root. `FEATURE_KEY`. 2 research routes: nonlinear, signals. `features`. 1 research route: root. `FeatureSpec`. 1 research route: root. `FeatureStatus`. 1 research route: root. `FeshbachReduction`. 1 research route: root. `fft_convolve`. 1 research route: signals. `fft_lowpass_1d`. 1 research route: signals. `fft_lowpass_2d`. 1 research route: signals. `fibonacci_companion_power`. 1 research route: coordinates. `fibonacci_factorial_basis`. 2 research routes: coordinates, generating. `fibonacci_numbers`. 2 research routes: coordinates, generating. `fibonacci_polynomial`. 1 research route: coordinates. `fibonacci_polynomial_family`. 1 research route: coordinates. `fibonacci_recurrence`. 1 research route: root. `fibonacci_recurrence_model`. 1 research route: coordinates. `fibonacci_sequence`. 1 research route: root. `Figure`. 1 research route: export. `FilterBankReport`. 1 research route: signals. `FilteredCorrectionProblem`. 2 research routes: root, nonlinear. `FilteredSpectralSequenceResult`. 1 research route: nonlinear. `FilteredVectorSpace`. 2 research routes: root, nonlinear. `FilterOutput`. 1 research route: signals. `finite_difference`. 2 research routes: root, signals. `finite_difference_coordinate_operator`. 1 research route: coordinates. `finite_frobenius_separator`. 1 research route: root. `finite_mask_carry_matrices`. 1 research route: generating. `finite_polyphase_blocks`. 1 research route: signals. `finite_polyphase_filter_kernels`. 1 research route: signals. `FiniteAbelianGroup`. 2 research routes: root, nonlinear. `FiniteBasis`. 2 research routes: root, coordinates. `FiniteCochainComplex`. 1 research route: root. `FiniteDifferenceDerivativeProvider`. 2 research routes: root, nonlinear. `FiniteField`. 1 research route: root. `FiniteFieldCoordinateTransform`. 2 research routes: root, coordinates. `FiniteFilterBank`. 1 research route: signals. `FiniteFilteredBranchResult`. 1 research route: nonlinear. `FiniteFilteredCochainComplex`. 2 research routes: root, nonlinear. `FiniteGroup`. 1 research route: root. `FiniteHeckePackets`. 1 research route: root. `FiniteLiftForest`. 1 research route: root. `FiniteLiftTree`. 2 research routes: root, nonlinear. `FiniteMaskCarryPlan`. 2 research routes: root, generating. `FiniteMonoidSeries`. 1 research route: generating. `FiniteNormalizedSeries`. 2 research routes: root, generating. `FinitePolyphaseKernel`. 1 research route: signals. `fir_filter`. 1 research route: signals. `fir_frequency_response`. 1 research route: signals. `fir_taps_to_series`. 1 research route: generating. `FIRFilter`. 1 research route: signals. `FIRKind`. 1 research route: signals. `FIRMode`. 1 research route: signals. `FIRSeriesAdapter`. 1 research route: generating. `first_frobenius_lift`. 1 research route: generating. `fixed_packet_leakage`. 1 research route: root. `formal_coordinate_from_iterable`. 1 research route: coordinates. `FormalCoordinateChange`. 2 research routes: root, coordinates. `FormalSeries`. 2 research routes: root, generating. `forward_difference_transform`. 2 research routes: root, coordinates. `fractional_power`. 1 research route: root. `frame_signal`. 1 research route: signals. `FrameBatch`. 1 research route: signals. `freeze_custom_function`. 2 research routes: root, generating. `FrequencyResponse`. 1 research route: signals. `frobenius_defect_mask`. 1 research route: generating. `FrobeniusOrbit`. 1 research route: root. `FrobeniusSpine`. 1 research route: root. `from_portable_data`. 1 research route: export. `from_serializable`. 2 research routes: root, export. `FrozenGeneratingFunction`. 2 research routes: root, generating. `fubini_identity`. 1 research route: root. `FunctionRegistry`. 2 research routes: root, generating. `fundamental_theorem`. 1 research route: root. `FundamentalHolonomy`. 1 research route: nonlinear.

C.8.7 Names beginning with G

`gamma_from_impedance`. 1 research route: signals. `GateStatus`. 1 research route: root. `gauss_sum`. 1 research route: root. `gaussian_binomial`. 1 research route: generating. `generalized_bell_digit_reduction`. 2 research routes: root, generating. `generalized_bell_numbers`. 1 research route: generating. `generalized_bell_parity`. 1 research route: generating. `generalized_bell_polynomials`. 1 research route: generating. `GeneratingBudget`. 2 research routes: root, generating. `get_polynomial_family`. 2 research routes: root, coordinates. `get_recurrence_model`. 2 research routes: root, coordinates. `get_sequence`. 1 research route: root. `get_settings`. 1 research route: root. `get_window`. 1 research route: signals. `GradedConvolutionResult`. 1 research route: nonlinear. `GradedConvolutionTerm`. 1 research route: nonlinear. `GradedPacketOperation`. 2 research routes: root, nonlinear. `GradingCertificate`. 1 research route: nonlinear. `guess_algebraic_gf`. 1 research route: generating. `guess_hypergeometric_ratio`. 1 research route: generating. `guess_linear_recurrence`. 1 research route: generating. `guess_p_recursive`. 1 research route: generating. `guess_quasipolynomial`. 1 research route: generating.

C.8.8 Names beginning with H

`haar_analyze`. 1 research route: signals. `haar_decompose`. 1 research route: signals. `haar_filter_bank`. 1 research route: signals. `haar_lipschitz_bound`. 1 research route: signals. `haar_matrix`. 1 research route: signals. `haar_packet_analyze`. 1 research route: signals. `haar_packet_synthesize`. 1 research route: signals. `haar_step_coefficient`. 1 research route: signals. `haar_synthesize`. 1 research route: signals. `haar_wavelet_transform`. 1 research route: coordinates. `HaarDecomposition`. 1 research route: signals. `HaarFilterBank`. 1 research route: signals. `HaarPacketTree`. 2 research routes: root, signals. `half_shift_distance`. 1 research route: signals. `Heading`. 1 research route: export. `HeisenbergModel`. 1 research route: root. `hermite_physicists_polynomial`. 1 research route: coordinates. `hermite_physicists_polynomial_family`. 1 research route: coordinates. `hermite_probabilists_polynomial`. 1 research route: coordinates. `hermite_probabilists_polynomial_family`. 1 research route: coordinates. `HiddenSolveResult`. 1 research route: nonlinear. `higher_maurer_cartan_packets`. 2 research routes: root, nonlinear. `HigherMaurerCartanResult`. 1 research route: nonlinear. `HilbertObstructionProjector`. 2 research routes: root, nonlinear. `HilbertObstructionResult`. 1 research route: nonlinear. `HolonomicRecurrence`. 1 research route: root. `HtmlRenderOptions`. 1 research route: export. `HurwitzSeries`. 1 research route: root. `hypergeometric_function`. 1 research route: generating. `HypergeometricGuess`. 1 research route: generating.

C.8.9 Names beginning with I

`identity`. 1 research route: root. `identity_formal_coordinate`. 1 research route: coordinates. `identity_matrix`. 1 research route: coordinates. `IdentityMap`. 1 research route: root. `impedance_from_gamma`. 1 research route: signals. `independent_direct_sum_seed_rank`. 1 research route: root. `InducedRepresentation`. 1 research route: root. `infer_export_format`. 1 research route: export. `INTEGER_DOMAIN`. 1 research route: generating. `integer_valuation`. 1 research route: generating. `IntegerDomain`. 1 research route: generating. `integral_coordinate_operator`. 1 research route: coordinates. `IntegralIdentity`. 1 research route: root. `IntegralResult`. 1 research route: root. `integrate`. 1 research route: root. `integrate_derivative_provider`. 1 research route: root. `integrate_formal_series`. 1 research route: root. `integrate_polynomial_coordinates`. 1 research route: root. `integrate_polynomial_oriented`. 1 research route: root. `integration_by_parts`. 1 research route: root. `IntegrationError`. 1 research route: root. `interpolate`. 1 research route: signals. `interpolation_transform`. 1 research route: coordinates. `intertwiner_space`. 2 research routes: root, coordinates. `IntertwinerSpace`. 2 research routes: root, coordinates. `IntertwiningResult`. 1 research route: nonlinear. `interval_integration`. 1 research route: root. `IntervalMeasure`. 1 research route: root. `inverse_matrix`. 1 research route: coordinates. `istft`. 1 research route: signals.

C.8.10 Names beginning with J

`jacobsthal_recurrence_model`. 1 research route: coordinates. `JaxDerivativeProvider`. 2 research routes: root, nonlinear. `JumpDetection`. 1 research route: signals. `JumpRecoveryResult`. 1 research route: signals.

C.8.11 Names beginning with K

`KatoTransport`. 2 research routes: root, nonlinear. `KomorebiDeprecationWarning`. 1 research route: root. `kummer_layer_distribution`. 1 research route: generating. `KummerLayerDistribution`. 1 research route: generating.

C.8.12 Names beginning with L

`labeled_composition_term_count`. 1 research route: nonlinear. `lagrange_interpolation_basis`. 1 research route: coordinates. `laguerre_polynomial`. 1 research route: coordinates. `laguerre_polynomial_family`. 1 research route: coordinates. `lah_number`. 1 research route: coordinates. `latex_escape`. 1 research route: export. `latex_label`. 1 research route: export. `LatexCompilation`. 1 research route: export. `LatexCompileOptions`. 2 research routes: root, export. `LatexEngine`. 2 research routes: root, export. `LatexRenderOptions`. 2 research routes: root, export. `lattice_polyphase_analyze`. 1 research route: signals. `lattice_polyphase_synthesize`. 1 research route: signals. `LatticePacketData`. 1 research route: root. `LatticePolyphaseCoordinates`. 1 research route: signals. `legendre_polynomial`. 1 research route: coordinates. `legendre_polynomial_family`. 1 research route: coordinates. `Let`. 1 research route: root. `let`. 1 research route: root. `lfilter`. 1 research route: signals. `lift_digit_sequence`. 1 research route: generating. `LiftStepResult`. 1 research route: nonlinear. `LiftTreeNode`. 1 research route: nonlinear. `LindbladGenerator`. 1 research route: root. `linear_recurrence_function`. 1 research route: generating. `LinearCharacter`. 1 research route: root. `LinearFilter`. 1 research route: signals. `LinearLiftProblem`. 2 research routes: root, nonlinear. `LinearMapType`. 1 research route: root. `LinearObstructionProblem`. 2 research routes: root, nonlinear. `LinearRealization`. 2 research routes: root, coordinates. `LinearRecurrence`. 1 research route: root. `LinearRecurrenceGuess`. 1 research route: generating. `LinearRefinementDefect`. 1 research route: root. `ListBlock`. 1 research route: export. `lms_filter`. 1 research route: signals. `load_behavioral_golden_fixture`. 1 research route: root. `load_beta_api_manifest`. 1 research route: root. `load_coordinate_object`. 2 research routes: root, coordinates. `load_coordinate_record`. 1 research route: coordinates. `load_packet_jet_snapshot_stream`. 2 research routes: root, nonlinear. `load_portable`. 2 research routes: root, export. `load_public_api_manifest`. 1 research route: root. `load_transform`. 1 research route: coordinates. `loads_portable`. 2 research routes: root, export. `local_normalized_kernel`. 1 research route: generating. `LowRankOperator`. 1 research route: root. `lp_cost`. 1 research route: signals. `lucas_polynomial`. 1 research route: coordinates. `lucas_polynomial_family`. 1 research route: coordinates. `lucas_recurrence_model`. 1 research route: coordinates. `LyapunovSchmidtDecomposition`. 1 research route: nonlinear. `LyapunovSchmidtPoint`. 1 research route: nonlinear. `LyapunovSchmidtReduction`. 2 research routes: root, nonlinear.

C.8.13 Names beginning with M

`mackey_tensor_packets`. 1 research route: root. `mahler_coefficients`. 1 research route: generating. `mahler_mask_inverse`. 2 research routes: root, generating. `mahler_mask_product`. 2 research routes: root, generating. `MahlerSeries`. 1 research route: root. `majorant_convergence`. 2 research routes: root, nonlinear. `MajorantConvergence`. 1 research route: nonlinear. `MarkovLumping`. 1 research route: root. `MathDocument`. 2 research routes: root, export. `Matrix`. 1 research route: coordinates. `matrix_add`. 1 research route: coordinates. `matrix_chain_multiply`. 1 research route: root. `matrix_chain_parenthesization`. 1 research route: root. `matrix_chain_plan`. 1 research route: root. `matrix_from_columns`. 1 research route: coordinates. `matrix_multiply`. 1 research route: coordinates. `matrix_power`. 1 research route: coordinates. `matrix_rank`. 1 research route: coordinates. `matrix_shape`. 1 research route: coordinates. `matrix_subtract`. 1 research route: coordinates. `matrix_units`. 1 research route: root. `matrix_vector_multiply`. 1 research route: coordinates. `MatrixChainPlan`. 1 research route: root. `MatrixChainTree`. 1 research route: root. `MatrixSemigroup`. 1 research route: root. `maurer_cartan_packets`. 2 research routes: root, nonlinear. `MaurerCartanResult`. 1 research route: nonlinear. `Measure`. 1 research route: root. `median_absolute_deviation`. 1 research route: signals. `MemoryKernel`. 1 research route: root. `minimal_prefix_period`. 1 research route: generating. `minimize_cartier_automaton`. 1 research route: generating. `mixed_radix_address`. 1 research route: signals. `mobius_integer`. 1 research route: coordinates. `modal_coordinate_system`. 1 research route: coordinates. `ModalCoordinateSystem`. 1 research route: coordinates. `ModularLinearSolution`. 1 research route: nonlinear. `ModularMatrix`. 1 research route: coordinates. `ModularVector`. 1 research route: coordinates. `monomial_polynomial_family`. 1 research route: coordinates. `monomial_to_falling_factorial_transform`. 1 research route: coordinates. `monomial_to_fibonacci_coefficient`. 1 research route: coordinates. `monomial_to_rising_factorial_transform`. 1 research route: coordinates. `MonomialAction`. 1 research route: root. `motzkin_sequence`. 1 research route: root. `MovingPacketSystem`. 2 research routes: root, nonlinear. `MultilinearOperation`. 2 research routes: root, nonlinear. `multiplication_coordinate_operator`. 1 research route: coordinates. `multiplicative_order_mod_prime`. 1 research route: generating. `multiplicative_series`. 1 research route: generating.

C.8.14 Names beginning with N

`newton_evaluation_transform`. 1 research route: coordinates. `newton_interpolation_basis`. 1 research route: coordinates. `nlms_filter`. 1 research route: signals. `nonlinear_cupy_available`. 2 research routes: root, nonlinear. `nonlinear_shift_filter`. 1 research route: signals. `NonlinearPacketMap`. 2 research routes: root, nonlinear. `NonlinearRefinementDefect`. 2 research routes: root, nonlinear. `NonlinearSchurElimination`. 2 research routes: root, nonlinear. `normal_form_digest`. 1 research route: root. `NormalForm`. 1 research route: root. `normalization_change_transform`. 2 research routes: root, coordinates. `normalize_expression`. 1 research route: root. `normalized_cyclotomic_expression`. 1 research route: generating. `NormalizedBasis`. 3 research routes: root, coordinates, generating. `NormalizedKernelResidue`. 1 research route: generating. `NormalizedMaskPlan`. 1 research route: generating. `NormalizedMonomialBasis`. 1 research route: generating. `nullspace`. 1 research route: coordinates. `NumericCoordinateTransform`. 2 research routes: root, coordinates.

C.8.15 Names beginning with O

`observability_block_matrix`. 1 research route: coordinates. `observability_coordinate_transform`. 1 research route: coordinates. `observability_matrix`. 2 research routes: root, coordinates. `ObstructionResult`. 1 research route: nonlinear. `ObstructionSquare`. 1 research route: nonlinear. `one_borrow_count`. 1 research route: generating. `open_packet_jet_snapshot_stream`. 2 research routes: root, nonlinear. `operator_change_of_coordinates`. 2 research routes: root, coordinates. `operator_commutator`. 1 research route: coordinates. `operator_matrix_between_families`. 1 research route: coordinates. `OperatorAlgebra`. 1 research route: root. `OperatorGrammar`. 1 research route: root. `OperatorMorphism`. 1 research route: root. `OperatorRealization`. 1 research route: root. `OperatorRelation`. 1 research route: root. `OperatorWord`. 1 research route: root. `ordered_rooted_trees`. 1 research route: nonlinear. `ordered_tree_count`. 1 research route: nonlinear. `ordered_trees_with_leaves`. 1 research route: nonlinear. `OrderedRootedTree`. 2 research routes: root, nonlinear. `ordinary_basis`. 3 research routes: root, coordinates, generating. `otsu_threshold`. 1 research route: signals. `overlap_add`. 1 research route: signals. `overlap_add_certificate`. 1 research route: signals. `overlap_add_convolve`. 1 research route: signals. `overlap_matrix_error`. 1 research route: signals. `overlap_partition_lp_error`. 1 research route: signals. `overlap_profile`. 1 research route: signals. `OverlapAddConvolver`. 1 research route: signals.

C.8.16 Names beginning with P

`p_adic_valuation_fraction`. 1 research route: generating. `p_free_orbit`. 1 research route: generating. `packet_energy`. 1 research route: signals. `packet_faa_di_bruno`. 2 research routes: root, nonlinear. `packet_jet_benchmark_contract`. 2 research routes: root, nonlinear. `PACKET_JET_CHUNK_SCHEMA`. 2 research routes: root, nonlinear. `PACKET_JET_CHUNK_SCHEMA_VERSION`. 2 research routes: root, nonlinear. `PACKET_JET_STREAM_SCHEMA`. 2 research routes: root, nonlinear. `PACKET_JET_STREAM_SCHEMA_VERSION`. 2 research routes: root, nonlinear. `packet_jet_support`. 2 research routes: root, nonlinear. `packet_product`. 1 research route: signals. `packet_taylor`. 2 research routes: root, nonlinear. `packet_tree_reconstruction`. 2 research routes: root, nonlinear. `PacketCoordinates`. 1 research route: root. `PacketDerivativeResult`. 1 research route: nonlinear. `PacketEstimate1D`. 1 research route: signals. `PacketIdentity`. 1 research route: generating. `PacketIR`. 1 research route: root. `PacketJet`. 2 research routes: root, nonlinear. `PacketJetAddress`. 1 research route: nonlinear. `PacketJetBatchResult`. 2 research routes: root, nonlinear. `PacketJetCoefficient`. 1 research route: nonlinear. `PacketJetComplexityEstimate`. 2 research routes: root, nonlinear. `PacketJetEvaluation`. 1 research route: nonlinear. `PacketJetExecutionPlan`. 2 research routes: root, nonlinear. `PacketJetFamily`. 2 research routes: root, nonlinear. `PacketJetInputGroup`. 1 research route: nonlinear. `PacketJetProfileReport`. 2 research routes: root, nonlinear. `PacketJetSnapshot`. 2 research routes: root, nonlinear. `PacketJetSnapshotStreamReader`. 2 research routes: root, nonlinear. `PacketJetStreamChunkRecord`. 2 research routes: root, nonlinear. `PacketJetStreamManifest`. 2 research routes: root, nonlinear. `PacketJetStreamSelection`. 2 research routes: root, nonlinear. `PacketJetStreamWriteResult`. 2 research routes: root, nonlinear. `PacketJetSupport`. 1 research route: nonlinear. `PacketLabel`. 1 research route: nonlinear. `PacketLayout`. 1 research route: root. `PacketMorphism`. 1 research route: root. `PacketOperator`. 1 research route: root. `PacketPath`. 1 research route: signals. `PacketRefinement`. 1 research route: root. `PacketSystem`. 1 research route: root. `PacketTaylorResult`. 1 research route: nonlinear. `PacketTreeResult`. 1 research route: nonlinear. `padic_valuation`. 1 research route: root. `padovan_recurrence_model`. 1 research route: coordinates. `pairing_invariant`. 1 research route: coordinates. `Paragraph`. 1 research route: export. `parseval_certificate`. 1 research route: signals. `Partition`. 1 research route: nonlinear. `partition_numbers`. 1 research route: generating. `partition_sequence`. 1 research route: root. `PatchingSupportReport`. 1 research route: root. `path_contributions`. 1 research route: root. `pell_polynomial`. 1 research route: coordinates. `pell_polynomial_family`. 1 research route: coordinates. `pell_recurrence_model`. 1 research route:

coordinates. `periodic_five_three_lifting`. 1 research route: signals. `periodic_laplacian`. 1 research route: root. `PeriodicFilterBank`. 2 research routes: root, signals. `PeriodicLiftingScheme`. 1 research route: signals. `periodogram`. 1 research route: signals. `permutation_transform`. 1 research route: coordinates. `phase_mobius`. 1 research route: signals. `PhaseTypeSurvival`. 1 research route: root. `PlanInstruction`. 1 research route: root. `pochhammer_basis`. 1 research route: generating. `pointed_subindex_polynomial`. 1 research route: generating. `PointedSubindexCertificate`. 1 research route: generating. `Polynomial`. 1 research route: coordinates. `polynomial_add`. 1 research route: coordinates. `polynomial_cartier`. 1 research route: generating. `polynomial_compose_affine`. 1 research route: coordinates. `polynomial_derivative`. 1 research route: coordinates. `polynomial_derivative_bound`. 1 research route: root. `polynomial_evaluate`. 1 research route: coordinates. `polynomial_extended_gcd`. 1 research route: coordinates. `polynomial_from_family_coordinates`. 1 research route: root. `polynomial_from_formal_series`. 1 research route: root. `polynomial_integral`. 1 research route: coordinates. `polynomial_integration_covector`. 1 research route: root. `polynomial_mask_coboundary`. 1 research route: generating. `polynomial_multiply`. 1 research route: coordinates. `polynomial_multiply_mod`. 1 research route: generating. `polynomial_operator`. 1 research route: coordinates. `polynomial_power_mod`. 1 research route: generating. `polynomial_scale`. 1 research route: coordinates. `polynomial_shift`. 1 research route: coordinates. `polynomial_subtract`. 1 research route: coordinates. `PolynomialCoboundaryResult`. 1 research route: generating. `PolynomialCoordinateOperator`. 2 research routes: root, coordinates. `PolynomialCoordinateSpace`. 1 research route: root. `PolynomialDerivativeProvider`. 2 research routes: root, nonlinear. `PolynomialFamily`. 2 research routes: root, coordinates. `PolynomialFamilyCatalog`. 1 research route: coordinates. `PolynomialFixedPointProblem`. 2 research routes: root, nonlinear. `PolynomialIntegrationCovector`. 1 research route: root. `PolynomialLiftProblem`. 2 research routes: root, nonlinear. `PolynomialPrimitive`. 1 research route: root. `polyphase_analyze`. 2 research routes: root, signals. `polyphase_convolution`. 1 research route: signals. `polyphase_filter_kernels`. 1 research route: signals. `polyphase_roundtrip_certificate`. 1 research route: signals. `polyphase_synthesize`. 1 research route: signals. `PolyphaseBlockMatrix`. 1 research route: signals. `PolyphaseConvolution`. 1 research route: signals. `PolyphaseCoordinates`. 1 research route: signals. `PolyphaseKernel`. 1 research route: signals. `PolyphaseSystem`. 2 research routes: root, signals. `portable_codecs`. 2 research routes: root, export. `portable_digest`. 2 research routes: root, export. `portable_migrations`. 2 research routes: root, export. `PORTABLE_SCHEMA`. 1 research route: export. `PORTABLE_SCHEMA_VERSION`. 1 research route: export. `PortableCodec`. 2 research routes: root, export. `PortableMigration`. 2 research routes: root, export. `positive_zero_string`. 1 research route: root. `PowerSpectrum`. 1 research route: signals. `PRecursiveGuess`. 1 research route: generating. `PresentedModule`. 1 research route: root. `prime_valuation_packets`. 1 research route: generating. `PrimeFieldDomain`. 1 research route: generating. `PrimePowerBinomial`. 1 research route: generating. `PrimePowerKernelCompiler`. 2 research routes: root, generating. `PrimePowerUnitCompiler`. 1 research route: generating. `primitive_certificate`. 1 research route: root. `primitive_matrix_equal`. 1 research route: root. `PrimitiveKind`. 1 research route: root. `product_measure`. 1 research route: root. `ProductMeasure`. 1 research route: root. `profile_operation`. 2 research routes: root, nonlinear. `profile_packet_jet_runtime`. 2 research routes: root, nonlinear. `ProjectiveIntertwinerEnvelope`. 1 research route: root. `ProjectiveLimitRecord`. 1 research route: nonlinear. `ProjectiveMultiplicityPacket`. 1 research route: root. `ProvenanceRecord`. 1 research route: root. `PrunedPacketCoefficients`. 1 research route: signals. `PublicApiManifest`. 1 research route: root. `PublicApiSymbol`. 1 research route: root. `pushforward_identity`. 1 research route: root. `pushforward_measure`. 1 research route: root. `PushforwardMeasure`. 1 research route: root.

C.8.17 Names beginning with Q

`q_binomial_support`. 1 research route: generating. `q_binomial_valuation_decomposition`. 2 research routes: root, generating. `q_binomial_valuation_direct`. 1 research route: generating. `q_factorial`. 1 research route: generating. `q_factorial_basis`. 1 research route: generating. `q_integer`. 1 research route: generating. `QKummerDecomposition`. 1 research route: generating. `quadratic_catalan_majorant`. 2 research routes: root, nonlinear. `QuadraticRefinement`. 1 research route: root. `QuadratureExactness`. 1 research route: root. `QuadratureRule`. 1 research route: root. `QuantumChannel`. 1 research route: root. `QuantumCode`. 1 research route: root. `QuantumFeshbachReduction`. 1 research route: root. `QuantumSeedSystem`. 1 research route: root. `QuasiPolynomialGuess`. 1 research route: generating.

C.8.18 Names beginning with R

`RamificationCliffordTower`. 1 research route: root. `RamificationStage`. 1 research route: root. `RATIONAL_DOMAIN`. 1 research route: generating. `rational_function`. 1 research route: generating. `rational_gf_from_recurrence`. 1 research route: generating. `rational_mask_coefficients_mod_prime`. 1 research route: generating. `RATIONAL_SPACE`. 1 research route: root. `RationalDomain`. 1 research route: generating. `RationalMaskAlgebraicCertificate`. 1 research route: generating. `RationalResamplingPlan`. 1 research route: signals. `RationalSpace`. 1 research route: root. `RawLatex`. 1 research route: export. `realization_defect`. 1 research route: coordinates. `reciprocal_coefficients`. 1 research route: root. `recompress_factors`. 1 research route: root. `reconstruction_error`. 1 research route: signals. `recover_initial_state`. 2 research routes: root, coordinates. `recover_jumps_subgaussian`. 1 research route: signals. `recover_separated_jumps`. 2 research routes: root, signals. `recover_vector_jumps`. 1 research route: signals. `recover_vector_jumps_subgaussian`. 1 research route: signals. `recurrence_analysis_transform`. 1 research route: coordinates. `recurrence_model_catalog`. 2 research routes: root, coordinates. `recurrence_polynomial`. 1 research route: coordinates. `recurrence_synthesis_transform`. 1 research route: coordinates. `RecurrenceCoordinateRecord`. 2 research routes: root, coordinates. `RecurrenceLike`. 1 research route: coordinates. `RecurrenceModel`. 2 research routes: root, coordinates. `reduce_exact_transform_mod_prime`. 1 research route: coordinates. `refinement_children`. 1 research route: signals. `RefinementTower`. 1 research route: root. `register_coordinate_codecs`. 1 research route: coordinates. `register_export_adapter`. 1 research route: export. `register_generating_codecs`. 1 research route: generating. `register_portable_codec`. 2 research routes: root, export. `register_portable_migration`. 2 research routes: root, export. `render_html`. 1 research route: export. `render_latex`. 2 research routes: root, export. `render_markdown`. 1 research route: export. `render_text`. 1 research route: export. `replay`. 1 research route: root. `replay_matrix`. 1 research route: root. `require`. 1 research route: nonlinear. `resample_poly`. 1 research route: signals. `resample_poly_result`. 1 research route: signals. `resampled_length`. 1 research route: signals. `ResamplingResult`. 1 research route: signals. `residue_analyze`. 1 research route: root. `residue_class_order`. 1 research route: coordinates. `residue_class_transform`. 2 research routes: root, coordinates. `residue_packet_system`. 1 research route: root. `residue_project`. 1 research route: signals. `ResidueRingDomain`. 1 research route: generating. `resolve_latex_engine`. 1 research route: export. `retained_packet_reconstruct`. 2 research routes: root, signals. `retained_packet_reconstruction`. 1 research route: signals. `RetainedPacketReconstruction`. 1 research route: signals. `RetainedPacketResult`. 1 research route: signals. `RewriteStep`. 1 research route: root. `RightInverseCorrectionProblem`. 2 research routes: root, nonlinear. `RightInverseCorrectionResult`. 1 research route: nonlinear. `rising_factorial_polynomial`. 1 research route: coordinates. `rising_factorial_polynomial_family`. 1 research route: coordinates. `rising_factorial_to_monomial_transform`. 1 research route: coordinates. `rising_to_falling_factorial_transform`. 1 research route: coordinates. `rls_filter`. 1 research route: signals. `root_filter_value`. 1 research route: generating. `rref`. 1 research route: coordinates. `run_behavioral_golden_fixture`. 1 research route: root. `RuntimeProfileSample`. 2 research routes: root, nonlinear. `RuntimeStageProfile`. 2 research routes: root, nonlinear.

C.8.19 Names beginning with S

`save_coordinate_object`. 2 research routes: root, coordinates. `save_coordinate_record`. 1 research route: coordinates. `save_packet_jet_snapshot_stream`. 2 research routes: root, nonlinear. `save_portable`. 2 research routes: root, export. `save_public_api_manifest`. 1 research route: root. `save_transform`. 1 research route: coordinates. `Scalar`. 1 research route: coordinates. `scalar_region_error`. 1 research route: signals. `scalar_region_lp_error`. 1 research route: signals. `Scale`. 1 research route: root. `scale`. 1 research route: root. `scaling_transform`. 1 research route: coordinates. `scan_residue_lanes`. 1 research route: generating. `schedule_unlimited`. 1 research route: root. `SchurDerivativeResult`. 1 research route: nonlinear. `SchurSecondDerivativeResult`. 1 research route: nonlinear. `search_decimation_relation`. 1 research route: generating. `secant_euler_from_fibonacci_coordinates`. 1 research route: coordinates. `SectionCycleAudit`. 1 research route: generating. `SeedMorphism`. 1 research route: root. `SeedSystem`. 1 research route: root. `semisimple_seed_rank`. 1 research route: root. `Sequence`. 1 research route: root. `sequence_coordinates_between_models`. 1 research route: coordinates. `sequence_document`. 2 research routes: root, export. `series_to_fir_adapter`. 1 research route: generating. `series_to_fir_taps`. 1 research route: generating. `SeriesTransferCertificate`. 1 research route: generating. `set_partitions`. 1 research route: nonlinear. `Settings`. 1 research route: root. `settings_context`. 1 research route: root. `shannon_entropy_cost`. 1 research route: signals. `shared_direct_sum_seed_bounds`. 1 research route: root. `ShiftPolynomial`. 2 research routes: root, coordinates. `signed_euler_number`. 1 research route: root. `signed_euler_numbers`. 1 research route: generating. `signed_secant_euler_numbers`. 1 research route: coordinates. `signed_section`. 1 research route: root. `similarity_from_cyclic_vectors`. 1 research route: coordinates. `SimplificationResult`. 1 research route: root. `simplify_expression`. 1 research route: root. `single_operator_seed_rank`. 1 research route: root.

`SingularPacket1D`. 2 research routes: root, signals. `siso_state_space`. 1 research route: coordinates. `smith_sensitivity`. 1 research route: signals. `SmithCongruenceProblem`. 1 research route: root. `smooth_haar_coefficient_bound`. 1 research route: signals. `snapshot_packet_jet`. 2 research routes: root, nonlinear. `solve_linear_system`. 1 research route: coordinates. `solve_mod_prime`. 2 research routes: root, nonlinear. `solve_polynomial_coboundary`. 1 research route: generating. `sorted_coordinate_transform`. 1 research route: coordinates. `SparsePolynomialDerivativeProvider`. 2 research routes: root, nonlinear. `SparseSymmetricTensor`. 2 research routes: root, nonlinear. `SparseTensorEntry`. 2 research routes: root, nonlinear. `spectral_dimension`. 1 research route: root. `SpectralAverage`. 1 research route: signals. `SpectralScaling`. 1 research route: signals. `SpectralSequenceEntry`. 1 research route: nonlinear. `SpectralSequencePage`. 1 research route: nonlinear. `spectrogram`. 1 research route: signals. `SpectrogramResult`. 1 research route: signals. `SpectrogramScaling`. 1 research route: signals. `split_mixed_radix_address`. 1 research route: signals. `STAGES`. 1 research route: root. `StageSpec`. 1 research route: root. `standard_basis`. 2 research routes: root, coordinates. `StandardWindow`. 1 research route: root. `StateRecovery`. 2 research routes: root, coordinates. `StateSpaceCoordinateCertificate`. 1 research route: coordinates. `StateSpaceModel`. 2 research routes: root, coordinates. `status`. 2 research routes: nonlinear, signals. `step_haar_coefficient`. 1 research route: signals. `step_location_lp_error`. 1 research route: signals. `stft`. 1 research route: signals. `STFTResult`. 1 research route: signals. `stirling_first_signed`. 1 research route: coordinates. `stirling_first_unsigned`. 1 research route: coordinates. `stirling_second`. 2 research routes: coordinates, nonlinear. `stream_fir_filter`. 1 research route: signals. `stream_lfilter`. 1 research route: signals. `stream_stft`. 1 research route: signals. `StreamedPacketJetEvaluation`. 2 research routes: root, nonlinear. `StreamingFIR`. 1 research route: signals. `StreamingLinearFilter`. 1 research route: signals. `StreamingSTFT`. 1 research route: signals. `StreamingSTFTBatch`. 1 research route: signals. `subgaussian_noise_bound`. 1 research route: signals. `subset_zeta_transform`. 1 research route: coordinates. `Sum`. 1 research route: root. `SupportComparison`. 1 research route: root. `SupportPreorder`. 1 research route: root. `sure_threshold`. 1 research route: signals. `Symbol`. 1 research route: root. `symbol`. 1 research route: root. `SympyDerivativeProvider`. 2 research routes: root, nonlinear. `synthesize_recurrence_coordinates`. 1 research route: coordinates.

C.8.20 Names beginning with T

`Table`. 2 research routes: root, export. `table_rows`. 1 research route: export. `TameWeilPacket`. 1 research route: root. `Task`. 1 research route: root. `tensor_axis_permutation_order`. 1 research route: coordinates. `tensor_axis_permutation_transform`. 1 research route: coordinates. `tensor_coordinate_transform`. 2 research routes: root, coordinates. `tensor_product_basis`. 1 research route: coordinates. `tensor_product_transform`. 1 research route: coordinates. `tensor_seed_rank_upper_bound`. 1 research route: root. `then`. 1 research route: root. `theta_polynomial`. 1 research route: root. `threshold_coefficients`. 1 research route: signals. `ThresholdMode`. 1 research route: signals. `ThresholdRule`. 1 research route: signals. `thue_morse_sequence`. 1 research route: root. `to_portable_data`. 1 research route: export. `to_serializable`. 2 research routes: root, export. `TorchDerivativeProvider`. 2 research routes: root, nonlinear. `transfer_section`. 1 research route: root. `transfer_tangent`. 1 research route: root. `TransferGraph`. 1 research route: root. `transform_sequence`. 1 research route: coordinates. `translation_transform`. 1 research route: coordinates. `transport_bilinear_form`. 1 research route: coordinates. `transport_covector`. 1 research route: coordinates. `transport_operator`. 1 research route: coordinates. `transport_polynomial_operator`. 1 research route: coordinates. `transport_rectangular_operator`. 1 research route: coordinates. `transport_tensor_components`. 1 research route: coordinates. `TransportEdge`. 2 research routes: root, nonlinear. `TransportGraph`. 2 research routes: root, nonlinear. `TransportRefinementResult`. 1 research route: nonlinear. `transpose`. 1 research route: coordinates. `TreeExpansionResult`. 1 research route: nonlinear. `TreeNode`. 1 research route: root. `TreeTerm`. 1 research route: nonlinear. `tribonacci_recurrence_model`. 1 research route: coordinates. `TruncatedPadic`. 1 research route: root. `TruncatedPadicDomain`. 1 research route: generating. `TruncatedPowerPacket`. 1 research route: signals. `TruncatedPowerTerm`. 1 research route: signals. `type_from_dict`. 1 research route: root. `type_to_dict`. 1 research route: root.

C.8.21 Names beginning with U

`UnifiedStage`. 1 research route: root. `UnifiedSystem`. 1 research route: root. `universal_threshold`. 1 research route: signals. `upsample`. 1 research route: signals.

C.8.22 Names beginning with V

validate_cupy_snapshot. 2 research routes: root, nonlinear. **Variance**. 1 research route: coordinates. **variation_of_constants_prefix**. 2 research routes: root, coordinates. **Vector**. 1 research route: coordinates. **VectorJumpRecoveryResult**. 1 research route: signals. **verify_cyclotomic_coboundary**. 1 research route: generating. **verify_cyclotomic_exponent_relation**. 1 research route: generating. **verify_finite_filtered_branch**. 2 research routes: root, nonlinear. **VisibilityTree**. 1 research route: root.

C.8.23 Names beginning with W

walsh_hadamard_transform. 1 research route: coordinates. **WalshHadamardOperator**. 1 research route: root. **warn_deprecated**. 1 research route: root. **wavelet_denoise**. 1 research route: signals. **WaveletDenoiseResult**. 1 research route: signals. **weakest_exactness**. 1 research route: root. **weighted_bell_digit_reduction**. 1 research route: generating. **weighted_factorial_power_bell_function**. 1 research route: generating. **weighted_generalized_bell_numbers**. 1 research route: generating. **weighted_generalized_bell_polynomials**. 1 research route: generating. **WeightedMonomialBasis**. 2 research routes: root, generating. **WeightedTransferEdge**. 1 research route: root. **WeightedTransferGraph**. 1 research route: root. **welch_psd**. 1 research route: signals. **window_metrics**. 1 research route: signals. **WindowMetrics**. 1 research route: signals. **WindowName**. 1 research route: signals. **WindowSpec**. 1 research route: signals.

C.8.24 Names beginning with Z

zero_borrow_count. 1 research route: generating. **zero_map**. 1 research route: root. **zero_matrix**. 1 research route: coordinates. **ZeroMap**. 1 research route: root.

C.8.25 Names beginning with Symbols and underscores

__version__. 1 research route: root.

C.9 Exact research signature index

The 1,312 research cards contain 923 exact manifest-signature values. The index treats literal `null` as one recorded value and preserves every quote, default, annotation, positional marker, and return annotation in the non-null signatures. Signature equality is textual manifest equality. It is not a claim that two implementations share behavior.

Signature class	Groups	Research cards
Literal `null`	1	36
Shared non-null signatures	244	598
Non-null signatures used by one card	678	678
Total	**923**	**1,312**

C.9.1 Literal null signature

SIG-NULL. 36 research cards. Kinds: `class` and `data`.

```
null

C.10 Alias and stability-tier crosswalk

This crosswalk joins all 1,526 card routes to the additional public routes named by their affirmative card identities. Callable cards that resolve to the same implementation object are placed in one alias group. Data exports are joined only when a card explicitly records the route relation. Negative same-spelling statements are excluded. This prevents distinct functions and equal or interned immutable values from becoming accidental aliases.

The strongest tier shown for a group applies only to the routes that carry that tier. A stable route does not promote a root, beta, or research route merely because both names resolve to the same Python object. The route-specific contract remains controlling.

Tier pattern in alias group	Groups	Card routes	All listed public routes
`stable+beta+research`	22	75	119
`stable+beta`	6	12	24
`stable+research`	51	126	230
`stable`	47	51	153
`beta+research`	55	149	149
`research`	959	1113	1113
Total	**1140**	**1,526**	**1,788**

C.10.1 Stable + Beta + Research route groups

AG-0001 `__version__`. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 **version**. Beta cards: B.1 **version**. Research cards: C.1A **version**. Additional public routes: `komorebi_math.api.v1.__version__`, `komorebi_math.v1.__version__`.

AG-0004 `ApiCompatibilityReport`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.compatibility`. Stable cards: A.9 ApiCompatibilityReport. Beta cards: B.1 ApiCompatibilityReport. Research cards: C.1A ApiCompatibilityReport. Additional public routes: `komorebi_math.api.v1.ApiCompatibilityReport`, `komorebi_math.v1.ApiCompatibilityReport`.

AG-0015 `Certificate`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.certificates`. Stable cards: A.2 Certificate. Beta cards: B.1 Certificate. Research cards: C.1A Certificate. Additional public routes: `komorebi_math.api.v1.Certificate`, `komorebi_math.v1.Certificate`.

AG-0023 `ComputationResult`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.certificates`. Stable cards: A.2 ComputationResult. Beta cards: B.1 ComputationResult. Research cards: C.1A ComputationResult. Additional public routes: `komorebi_math.api.v1.ComputationResult`, `komorebi_math.v1.ComputationResult`.

AG-0024 `ConditionalResult`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.certificates`. Stable cards: A.2 ConditionalResult. Beta cards: B.1 ConditionalResult. Research cards: C.1A ConditionalResult. Additional public routes: `komorebi_math.api.v1.ConditionalResult`, `komorebi_math.v1.ConditionalResult`.

AG-0035 `dumps_portable`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 dumps_portable. Beta cards: B.4 dumps_portable. Research cards: C.1F dumps_portable, C.6 dumps_portable. Additional public routes: `komorebi_math.api.v1.dumps_portable`, `komorebi_math.v1.dumps_portable`.

AG-0037 `Exactness`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.certificates`. Stable cards: A.2 Exactness. Beta cards: B.1 Exactness. Research cards: C.1A Exactness. Additional public routes: `komorebi_math.api.v1.Exactness`, `komorebi_math.v1.Exactness`.

AG-0045 `from_portable_data`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 from_portable_data. Beta cards: B.4 from_portable_data. Research cards: C.6 from_portable_data. Additional public routes: `komorebi_math.api.v1.from_portable_data`, `komorebi_math.v1.from_portable_data`.

AG-0054 `load_portable`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 load_portable. Beta cards: B.4 load_portable. Research cards: C.6 load_portable, C.1F load_portable. Additional public routes: `komorebi_math.api.v1.load_portable`, `komorebi_math.v1.load_portable`.

AG-0058 `loads_portable`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 loads_portable. Beta cards: B.4 loads_portable. Research cards: C.6 loads_portable, C.1F loads_portable. Additional public routes: `komorebi_math.api.v1.loads_portable`, `komorebi_math.v1.loads_portable`.

AG-0072 `PacketSystem`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.packets`. Stable cards: A.3 PacketSystem. Beta cards: B.1 PacketSystem. Research cards: C.1D PacketSystem. Additional public routes: `komorebi_math.api.v1.PacketSystem`, `komorebi_math.v1.PacketSystem`.

AG-0085 `portable_codecs`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 portable_codecs. Beta cards: B.4 portable_codecs. Research cards: C.6 portable_codecs, C.1F portable_codecs. Additional public routes: `komorebi_math.api.v1.portable_codecs`, `komorebi_math.v1.portable_codecs`.

AG-0086 `portable_digest`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 portable_digest. Beta cards: B.4 portable_digest. Research cards: C.6 portable_digest, C.1F portable_digest. Additional public routes: `komorebi_math.api.v1.portable_digest`, `komorebi_math.v1.portable_digest`.

AG-0087 `portable_migrations`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 portable_migrations. Beta cards: B.4 portable_migrations. Research cards: C.6 portable_migrations, C.1F portable_migrations. Additional public routes: `komorebi_math.api.v1.portable_migrations`, `komorebi_math.v1.portable_migrations`.

AG-0088 `PORTABLE_SCHEMA`. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 PORTABLE_SCHEMA. Beta cards: B.4 PORTABLE_SCHEMA. Research cards: C.6 PORTABLE_SCHEMA. Additional public routes: `komorebi_math.api.v1.PORTABLE_SCHEMA`, `komorebi_math.v1.PORTABLE_SCHEMA`.

AG-0089 **`PORTABLE_SCHEMA_VERSION`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 PORTABLE_SCHEMA_VERSION. Beta cards: B.4 PORTABLE_SCHEMA_VERSION. Research cards: C.6 PORTABLE_SCHEMA_VERSION. Additional public routes: `komorebi_math.api.v1.PORTABLE_SCHEMA_VERSION`, `komorebi_math.v1.PORTABLE_SCHEMA_VERSION`.

AG-0090 **`PortableCodec`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 PortableCodec. Beta cards: B.4 PortableCodec. Research cards: C.1F PortableCodec, C.6 PortableCodec. Additional public routes: `komorebi_math.api.v1.PortableCodec`, `komorebi_math.v1.PortableCodec`.

AG-0094 **`PortableMigration`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 PortableMigration. Beta cards: B.4 PortableMigration. Research cards: C.1F PortableMigration, C.6 PortableMigration. Additional public routes: `komorebi_math.api.v1.PortableMigration`, `komorebi_math.v1.PortableMigration`.

AG-0095 **`PublicApiManifest`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.compatibility`. Stable cards: A.9 PublicApiManifest. Beta cards: B.1 PublicApiManifest. Research cards: C.1A PublicApiManifest. Additional public routes: `komorebi_math.api.v1.PublicApiManifest`, `komorebi_math.v1.PublicApiManifest`.

AG-0096 **`PublicApiSymbol`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.compatibility`. Stable cards: A.9 PublicApiSymbol. Beta cards: B.1 PublicApiSymbol. Research cards: C.1A PublicApiSymbol. Additional public routes: `komorebi_math.api.v1.PublicApiSymbol`, `komorebi_math.v1.PublicApiSymbol`.

AG-0108 **`save_portable`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 save_portable. Beta cards: B.4 save_portable. Research cards: C.6 save_portable, C.1F save_portable. Additional public routes: `komorebi_math.api.v1.save_portable`, `komorebi_math.v1.save_portable`.

AG-0123 **`to_portable_data`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Stable cards: A.8 to_portable_data. Beta cards: B.4 to_portable_data. Research cards: C.6 to_portable_data. Additional public routes: `komorebi_math.api.v1.to_portable_data`, `komorebi_math.v1.to_portable_data`.

C.10.2 Stable + Beta route groups

AG-0011 **`AssumptionError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 AssumptionError. Beta cards: B.1 AssumptionError. Additional public routes: `komorebi_math.api.v1.AssumptionError`, `komorebi_math.v1.AssumptionError`.

AG-0012 **`BackendUnavailableError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 BackendUnavailableError. Beta cards: B.1 BackendUnavailableError. Additional public routes: `komorebi_math.api.v1.BackendUnavailableError`, `komorebi_math.v1.BackendUnavailableError`.

AG-0033 **`DimensionError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 DimensionError. Beta cards: B.1 DimensionError. Additional public routes: `komorebi_math.api.v1.DimensionError`, `komorebi_math.v1.DimensionError`.

AG-0038 **`ExactnessError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 ExactnessError. Beta cards: B.1 ExactnessError. Additional public routes: `komorebi_math.api.v1.ExactnessError`, `komorebi_math.v1.ExactnessError`.

AG-0048 **`KomorebiMathError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 KomorebiMathError. Beta cards: B.1 KomorebiMathError. Additional public routes: `komorebi_math.api.v1.KomorebiMathError`, `komorebi_math.v1.KomorebiMathError`.

AG-0126 **`ValidationError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 ValidationError. Beta cards: B.1 ValidationError. Additional public routes: `komorebi_math.api.v1.ValidationError`, `komorebi_math.v1.ValidationError`.

C.10.3 Stable + Research route groups

AG-0002 `AnalysisSynthesisBlocks`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.analysis_synthesis`. Stable cards: A.4 AnalysisSynthesisBlocks. Research cards: C.1C AnalysisSynthesisBlocks, C.2C AnalysisSynthesisBlocks. Additional public routes: `komorebi_math.api.v1.AnalysisSynthesisBlocks`, `komorebi_math.v1.AnalysisSynthesisBlocks`.

AG-0003 `AnalysisSynthesisSystem`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.analysis_synthesis`. Stable cards: A.4 AnalysisSynthesisSystem. Research cards: C.1C AnalysisSynthesisSystem, C.2C AnalysisSynthesisSystem. Additional public routes: `komorebi_math.api.v1.AnalysisSynthesisSystem`, `komorebi_math.v1.AnalysisSynthesisSystem`.

AG-0010 `Arrow`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.grammar`. Stable cards: A.3 Arrow. Research cards: C.1D Arrow. Additional public routes: `komorebi_math.api.v1.Arrow`, `komorebi_math.v1.Arrow`.

AG-0013 `basis_from_matrix`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.coordinates.basis`. Stable cards: A.4 basis_from_matrix. Research cards: C.1C basis_from_matrix, C.2C basis_from_matrix. Additional public routes: `komorebi_math.api.v1.basis_from_matrix`, `komorebi_math.v1.basis_from_matrix`.

AG-0014 `block_from_paths`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.core.transfer`. Stable cards: A.3 block_from_paths. Research cards: C.1D block_from_paths. Additional public routes: `komorebi_math.api.v1.block_from_paths`, `komorebi_math.v1.block_from_paths`.

AG-0021 `common_refinement`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.towers`. Stable cards: A.5 common_refinement. Research cards: C.1G common_refinement. Additional public routes: `komorebi_math.api.v1.common_refinement`, `komorebi_math.v1.common_refinement`.

AG-0025 `configure`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.config`. Stable cards: A.2 configure. Research cards: C.1A configure. Additional public routes: `komorebi_math.api.v1.configure`, `komorebi_math.v1.configure`.

AG-0026 `connection_transform`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Stable cards: A.4 connection_transform. Research cards: C.1C connection_transform, C.2B connection_transform. Additional public routes: `komorebi_math.api.v1.connection_transform`, `komorebi_math.v1.connection_transform`.

AG-0027 `CoordinateAtlas`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.basis`. Stable cards: A.4 CoordinateAtlas. Research cards: C.1C CoordinateAtlas, C.2C CoordinateAtlas. Additional public routes: `komorebi_math.api.v1.CoordinateAtlas`, `komorebi_math.v1.CoordinateAtlas`.

AG-0028 `CoordinateTransform`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.transform`. Stable cards: A.4 CoordinateTransform, A.4 ExactCoordinateTransform. Research cards: C.1C CoordinateTransform, C.2C CoordinateTransform, C.2C ExactCoordinateTransform. Additional public routes: `komorebi_math.api.v1.CoordinateTransform`, `komorebi_math.api.v1.ExactCoordinateTransform`, `komorebi_math.v1.CoordinateTransform`, `komorebi_math.v1.ExactCoordinateTransform`.

AG-0034 `DocumentMetadata`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Stable cards: A.8 DocumentMetadata. Research cards: C.1F DocumentMetadata, C.6 DocumentMetadata. Additional public routes: `komorebi_math.api.v1.DocumentMetadata`, `komorebi_math.v1.DocumentMetadata`.

AG-0036 `Equation`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Stable cards: A.8 Equation. Research cards: C.1F Equation, C.6 Equation. Additional public routes: `komorebi_math.api.v1.Equation`, `komorebi_math.v1.Equation`.

AG-0039 `factorial_power_basis`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Stable cards: A.6 factorial_power_basis. Research cards: C.1F factorial_power_basis, C.3A factorial_power_basis. Additional public routes: `komorebi_math.api.v1.factorial_power_basis`, `komorebi_math.v1.factorial_power_basis`.

AG-0040 `FiniteBasis`. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.basis`. Stable cards: A.4 FiniteBasis. Research cards: C.1C FiniteBasis, C.2C FiniteBasis. Additional public routes: `komorebi_math.api.v1.FiniteBasis`, `komorebi_math.v1.FiniteBasis`.

AG-0041 `formal_coordinate_from_iterable`. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.coordinates.formal`. Stable cards: A.4 formal_coordinate_from_iterable. Research cards: C.2C formal_coordinate_

from_iterable. Additional public routes: `komorebi_math.api.v1.formal_coordinate_from_iterable`, `komorebi_math.v1.formal_coordinate_from_iterable`.

AG-0042 **`FormalCoordinateChange`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.formal`. Stable cards: A.4 FormalCoordinateChange. Research cards: C.1C FormalCoordinateChange, C.2C FormalCoordinateChange. Additional public routes: `komorebi_math.api.v1.FormalCoordinateChange`, `komorebi_math.v1.FormalCoordinateChange`.

AG-0043 **`FormalSeries`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.generating.series`. Stable cards: A.6 FormalSeries. Research cards: C.1F FormalSeries, C.3A FormalSeries. Additional public routes: `komorebi_math.api.v1.FormalSeries`, `komorebi_math.v1.FormalSeries`.

AG-0044 **`forward_difference_transform`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Stable cards: A.4 forward_difference_transform. Research cards: C.2A forward_difference_transform, C.1C forward_difference_transform. Additional public routes: `komorebi_math.api.v1.forward_difference_transform`, `komorebi_math.v1.forward_difference_transform`.

AG-0046 **`get_polynomial_family`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Stable cards: A.4 get_polynomial_family. Research cards: C.2B get_polynomial_family, C.1C get_polynomial_family. Additional public routes: `komorebi_math.api.v1.get_polynomial_family`, `komorebi_math.v1.get_polynomial_family`.

AG-0047 **`get_settings`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.config`. Stable cards: A.2 get_settings. Research cards: C.1A get_settings. Additional public routes: `komorebi_math.api.v1.get_settings`, `komorebi_math.v1.get_settings`.

AG-0049 **`lattice_polyphase_analyze`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 lattice_polyphase_analyze. Research cards: C.4B lattice_polyphase_analyze. Additional public routes: `komorebi_math.api.v1.lattice_polyphase_analyze`, `komorebi_math.v1.lattice_polyphase_analyze`.

AG-0051 **`lattice_polyphase_synthesize`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 lattice_polyphase_synthesize. Research cards: C.4B lattice_polyphase_synthesize. Additional public routes: `komorebi_math.api.v1.lattice_polyphase_synthesize`, `komorebi_math.v1.lattice_polyphase_synthesize`.

AG-0052 **`LatticePolyphaseCoordinates`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 LatticePolyphaseCoordinates. Research cards: C.4B LatticePolyphaseCoordinates. Additional public routes: `komorebi_math.api.v1.LatticePolyphaseCoordinates`, `komorebi_math.v1.LatticePolyphaseCoordinates`.

AG-0060 **`MathDocument`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Stable cards: A.8 MathDocument. Research cards: C.1F MathDocument, C.6 MathDocument. Additional public routes: `komorebi_math.api.v1.MathDocument`, `komorebi_math.v1.MathDocument`.

AG-0063 **`NumericCoordinateTransform`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.coordinates.numeric`. Stable cards: A.4 NumericCoordinateTransform. Research cards: C.1C NumericCoordinateTransform, C.2C NumericCoordinateTransform. Additional public routes: `komorebi_math.api.v1.NumericCoordinateTransform`, `komorebi_math.v1.NumericCoordinateTransform`.

AG-0064 **`OperatorGrammar`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.grammar`. Stable cards: A.3 OperatorGrammar. Research cards: C.1D OperatorGrammar. Additional public routes: `komorebi_math.api.v1.OperatorGrammar`, `komorebi_math.v1.OperatorGrammar`.

AG-0065 **`OperatorRealization`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.realization`. Stable cards: A.3 OperatorRealization. Research cards: C.1D OperatorRealization. Additional public routes: `komorebi_math.api.v1.OperatorRealization`, `komorebi_math.v1.OperatorRealization`.

AG-0066 **`OperatorRelation`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.grammar`. Stable cards: A.3 OperatorRelation. Research cards: C.1D OperatorRelation. Additional public routes: `komorebi_math.api.v1.OperatorRelation`, `komorebi_math.v1.OperatorRelation`.

AG-0067 **`OperatorWord`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.grammar`. Stable cards: A.3 OperatorWord. Research cards: C.1D OperatorWord. Additional public routes: `komorebi_math.api.v1.OperatorWord`, `komorebi_math.v1.OperatorWord`.

AG-0068 **`ordinary_generating_basis`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Stable cards: A.6 ordinary_generating_basis. Research cards: C.2C ordinary_basis, C.3A ordinary_basis, C.1F ordinary_basis. Additional public routes: `komorebi_math.api.v1.ordinary_generating_basis`, `komorebi_math.v1.ordinary_generating_basis`.

AG-0069 **`PacketCoordinates`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.packets`. Stable cards: A.3 PacketCoordinates. Research cards: C.1D PacketCoordinates. Additional public routes: `komorebi_math.api.v1.PacketCoordinates`, `komorebi_math.v1.PacketCoordinates`.

AG-0070 **`PacketOperator`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.operators`. Stable cards: A.3 PacketOperator. Research cards: C.1D PacketOperator. Additional public routes: `komorebi_math.api.v1.PacketOperator`, `komorebi_math.v1.PacketOperator`.

AG-0071 **`PacketRefinement`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.refinement.towers`. Stable cards: A.5 PacketRefinement. Research cards: C.1G PacketRefinement. Additional public routes: `komorebi_math.api.v1.PacketRefinement`, `komorebi_math.v1.PacketRefinement`.

AG-0073 **`Paragraph`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Stable cards: A.8 Paragraph. Research cards: C.6 Paragraph. Additional public routes: `komorebi_math.api.v1.Paragraph`, `komorebi_math.v1.Paragraph`.

AG-0074 **`path_contributions`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.core.transfer`. Stable cards: A.3 path_contributions. Research cards: C.1D path_contributions. Additional public routes: `komorebi_math.api.v1.path_contributions`, `komorebi_math.v1.path_contributions`.

AG-0077 **`polyphase_roundtrip_certificate`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 polyphase_roundtrip_certificate. Research cards: C.4B polyphase_roundtrip_certificate. Additional public routes: `komorebi_math.api.v1.polyphase_roundtrip_certificate`, `komorebi_math.v1.polyphase_roundtrip_certificate`.

AG-0079 **`PolyphaseCoordinates`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 PolyphaseCoordinates. Research cards: C.4B PolyphaseCoordinates. Additional public routes: `komorebi_math.api.v1.PolyphaseCoordinates`, `komorebi_math.v1.PolyphaseCoordinates`.

AG-0082 **`PolyphaseSystem`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 PolyphaseSystem. Research cards: C.1F PolyphaseSystem, C.4B PolyphaseSystem. Additional public routes: `komorebi_math.api.v1.PolyphaseSystem`, `komorebi_math.v1.PolyphaseSystem`.

AG-0097 **`refinement_children`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 refinement_children. Research cards: C.4B refinement_children. Additional public routes: `komorebi_math.api.v1.refinement_children`, `komorebi_math.v1.refinement_children`.

AG-0098 **`RefinementTower`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.refinement.towers`. Stable cards: A.5 RefinementTower. Research cards: C.1G RefinementTower. Additional public routes: `komorebi_math.api.v1.RefinementTower`, `komorebi_math.v1.RefinementTower`.

AG-0100 **`render_latex`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.renderers`. Stable cards: A.8 render_latex. Research cards: C.6 render_latex, C.1F render_latex. Additional public routes: `komorebi_math.api.v1.render_latex`, `komorebi_math.v1.render_latex`.

AG-0101 **`render_markdown`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.export.renderers`. Stable cards: A.8 render_markdown. Research cards: C.6 render_markdown. Additional public routes: `komorebi_math.api.v1.render_markdown`, `komorebi_math.v1.render_markdown`.

AG-0102 **`residue_analyze`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.residue`. Stable cards: A.5 residue_analyze. Research cards: C.1G residue_analyze. Additional public routes: `komorebi_math.api.v1.residue_analyze`, `komorebi_math.v1.residue_analyze`.

AG-0103 **`residue_project`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 residue_project. Research cards: C.4B residue_project. Additional public routes: `komorebi_math.api.v1.residue_project`, `komorebi_math.v1.residue_project`.

AG-0110 **`SeedSystem`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.seeds`. Stable cards: A.3 SeedSystem. Research cards: C.1D SeedSystem. Additional public routes: `komorebi_math.api.v1.SeedSystem`, `komorebi_math.v1.SeedSystem`.

AG-0111 **`Settings`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.config`. Stable cards: A.2 Settings. Research cards: C.1A Settings. Additional public routes: `komorebi_math.api.v1.Settings`, `komorebi_math.v1.Settings`.

AG-0112 **`settings_context`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.config`. Stable cards: A.2 settings_context. Research cards: C.1A settings_context. Additional public routes: `komorebi_math.api.v1.settings_context`, `komorebi_math.v1.settings_context`.

AG-0113 **`signal_polyphase_analyze`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 signal_polyphase_analyze. Research cards: C.1F polyphase_analyze, C.4B polyphase_analyze. Additional public routes: `komorebi_math.api.v1.signal_polyphase_analyze`, `komorebi_math.v1.signal_polyphase_analyze`.

AG-0114 **`signal_polyphase_synthesize`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Stable cards: A.7 signal_polyphase_synthesize. Research cards: C.4B polyphase_synthesize. Additional public routes: `komorebi_math.api.v1.signal_polyphase_synthesize`, `komorebi_math.v1.signal_polyphase_synthesize`.

AG-0122 **`standard_basis`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.coordinates.basis`. Stable cards: A.4 standard_basis. Research cards: C.2C standard_basis, C.1C standard_basis. Additional public routes: `komorebi_math.api.v1.standard_basis`, `komorebi_math.v1.standard_basis`.

AG-0124 **`TransferGraph`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.graphs`. Stable cards: A.3 TransferGraph. Research cards: C.1D TransferGraph. Additional public routes: `komorebi_math.api.v1.TransferGraph`, `komorebi_math.v1.TransferGraph`.

C.10.4 Stable route groups

AG-0005 **`arithmetic_mixed_radix_address`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.polyphase`. Stable cards: A.5 arithmetic_mixed_radix_address. Additional public routes: `komorebi_math.api.v1.arithmetic_mixed_radix_address`, `komorebi_math.v1.arithmetic_mixed_radix_address`.

AG-0006 **`arithmetic_mixed_radix_digits`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.polyphase`. Stable cards: A.5 arithmetic_mixed_radix_digits. Additional public routes: `komorebi_math.api.v1.arithmetic_mixed_radix_digits`, `komorebi_math.v1.arithmetic_mixed_radix_digits`.

AG-0007 **`arithmetic_polyphase_analyze`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.polyphase`. Stable cards: A.5 arithmetic_polyphase_analyze. Additional public routes: `komorebi_math.api.v1.arithmetic_polyphase_analyze`, `komorebi_math.v1.arithmetic_polyphase_analyze`.

AG-0008 **`arithmetic_polyphase_synthesize`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.polyphase`. Stable cards: A.5 arithmetic_polyphase_synthesize. Additional public routes: `komorebi_math.api.v1.arithmetic_polyphase_synthesize`, `komorebi_math.v1.arithmetic_polyphase_synthesize`.

AG-0009 **`ArithmeticPolyphase`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.polyphase`. Stable cards: A.5 ArithmeticPolyphase. Additional public routes: `komorebi_math.api.v1.ArithmeticPolyphase`, `komorebi_math.v1.ArithmeticPolyphase`.

AG-0016 **`check_portable_codec_contract`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 check_portable_codec_contract. Additional public routes: `komorebi_math.api.v1.check_portable_codec_contract`, `komorebi_math.v1.check_portable_codec_contract`.

AG-0017 **`check_stable_api`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Stable cards: A.9 check_stable_api. Additional public routes: `komorebi_math.api.v1.check_stable_api`, `komorebi_math.v1.check_stable_api`.

AG-0018 **`check_stable_contract`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.stable_contract`. Stable cards: A.9 check_stable_contract. Additional public routes: `komorebi_math.api.v1.check_stable_contract`, `komorebi_math.v1.check_stable_contract`.

AG-0019 **`coarsen_lattice_polyphase`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 coarsen_lattice_polyphase, A.5 lattice_polyphase_coarsen. Additional public routes: `komorebi_math.api.v1.coarsen_lattice_polyphase`, `komorebi_math.api.v1.lattice_polyphase_coarsen`, `komorebi_math.v1.coarsen_lattice_polyphase`, `komorebi_math.v1.lattice_polyphase_coarsen`.

AG-0020 **`coarsen_polyphase`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 coarsen_polyphase, A.5 polyphase_coarsen. Additional public routes: `komorebi_math.api.v1.coarsen_polyphase`, `komorebi_math.api.v1.polyphase_coarsen`, `komorebi_math.v1.coarsen_polyphase`, `komorebi_math.v1.polyphase_coarsen`.

AG-0022 **`compare_portable_codec_contract`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 compare_portable_codec_contract. Additional public routes: `komorebi_math.api.v1.compare_portable_codec_contract`, `komorebi_math.v1.compare_portable_codec_contract`.

AG-0029 **`create_portable_codec_contract`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 create_portable_codec_contract. Additional public routes: `komorebi_math.api.v1.create_portable_codec_contract`, `komorebi_math.v1.create_portable_codec_contract`.

AG-0030 **`create_stable_api_manifest`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Stable cards: A.9 create_stable_api_manifest. Additional public routes: `komorebi_math.api.v1.create_stable_api_manifest`, `komorebi_math.v1.create_stable_api_manifest`.

AG-0031 **`DEFAULT_PORTABLE_CODEC_CONTRACT`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `pathlib`. Stable cards: A.1 DEFAULT_PORTABLE_CODEC_CONTRACT. Additional public routes: `komorebi_math.api.v1.DEFAULT_PORTABLE_CODEC_CONTRACT`, `komorebi_math.v1.DEFAULT_PORTABLE_CODEC_CONTRACT`.

AG-0032 **`DEFAULT_STABLE_SEMANTICS_FIXTURE`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `pathlib`. Stable cards: A.1 DEFAULT_STABLE_SEMANTICS_FIXTURE. Additional public routes: `komorebi_math.api.v1.DEFAULT_STABLE_SEMANTICS_FIXTURE`, `komorebi_math.v1.DEFAULT_STABLE_SEMANTICS_FIXTURE`.

AG-0050 **`lattice_polyphase_refine`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 lattice_polyphase_refine, A.5 refine_lattice_polyphase. Additional public routes: `komorebi_math.api.v1.lattice_polyphase_refine`, `komorebi_math.api.v1.refine_lattice_polyphase`, `komorebi_math.v1.lattice_polyphase_refine`, `komorebi_math.v1.refine_lattice_polyphase`.

AG-0053 **`LatticePolyphaseRefinement`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 LatticePolyphaseRefinement. Additional public routes: `komorebi_math.api.v1.LatticePolyphaseRefinement`, `komorebi_math.v1.LatticePolyphaseRefinement`.

AG-0055 **`load_portable_codec_contract`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 load_portable_codec_contract. Additional public routes: `komorebi_math.api.v1.load_portable_codec_contract`, `komorebi_math.v1.load_portable_codec_contract`.

AG-0056 **`load_stable_api_manifest`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Stable cards: A.9 load_stable_api_manifest. Additional public routes: `komorebi_math.api.v1.load_stable_api_manifest`, `komorebi_math.v1.load_stable_api_manifest`.

AG-0057 **`load_stable_semantics_fixture`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.stable_semantics`. Stable cards: A.9 load_stable_semantics_fixture. Additional public routes: `komorebi_math.api.v1.load_stable_semantics_fixture`, `komorebi_math.v1.load_stable_semantics_fixture`.

AG-0059 **`mahler_polyphase`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.polyphase`. Stable cards: A.5 mahler_polyphase. Additional public routes: `komorebi_math.api.v1.mahler_polyphase`, `komorebi_math.v1.mahler_polyphase`.

AG-0061 **`nested_residue_address`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.residue`. Stable cards: A.5 nested_residue_address. Additional public routes: `komorebi_math.api.v1.nested_residue_address`, `komorebi_math.v1.nested_residue_address`.

AG-0062 **`nested_residue_analysis`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.residue`. Stable cards: A.5 nested_residue_analysis. Additional public routes: `komorebi_math.api.v1.nested_residue_analysis`, `komorebi_math.v1.nested_residue_analysis`.

AG-0075 **`polyphase_refine`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 polyphase_refine, A.5 refine_polyphase. Additional public routes: `komorebi_math.api.v1.polyphase_refine`, `komorebi_math.api.v1.refine_polyphase`, `komorebi_math.v1.polyphase_refine`, `komorebi_math.v1.refine_polyphase`.

AG-0076 **`polyphase_refinement_certificate`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 polyphase_refinement_certificate. Additional public routes: `komorebi_math.api.v1.polyphase_refinement_certificate`, `komorebi_math.v1.polyphase_refinement_certificate`.

AG-0078 **`PolyphaseCoordinateRecord`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `types`. Stable cards: A.5 PolyphaseCoordinateRecord. Additional public routes: `komorebi_math.api.v1.PolyphaseCoordinateRecord`, `komorebi_math.v1.PolyphaseCoordinateRecord`.

AG-0080 **`PolyphaseRefinement`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 PolyphaseRefinement. Additional public routes: `komorebi_math.api.v1.PolyphaseRefinement`, `komorebi_math.v1.PolyphaseRefinement`.

AG-0081 **`PolyphaseRefinementTower`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.refinement.polyphase`. Stable cards: A.5 PolyphaseRefinementTower. Additional public routes: `komorebi_math.api.v1.PolyphaseRefinementTower`, `komorebi_math.v1.PolyphaseRefinementTower`.

AG-0083 **`PORTABLE_CODEC_CONTRACT_SCHEMA`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 PORTABLE_CODEC_CONTRACT_SCHEMA. Additional public routes: `komorebi_math.api.v1.PORTABLE_CODEC_CONTRACT_SCHEMA`, `komorebi_math.v1.PORTABLE_CODEC_CONTRACT_SCHEMA`.

AG-0084 **`PORTABLE_CODEC_CONTRACT_SCHEMA_VERSION`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 PORTABLE_CODEC_CONTRACT_SCHEMA_VERSION. Additional public routes: `komorebi_math.api.v1.PORTABLE_CODEC_CONTRACT_SCHEMA_VERSION`, `komorebi_math.v1.PORTABLE_CODEC_CONTRACT_SCHEMA_VERSION`.

AG-0091 **`PortableCodecCompatibilityReport`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 PortableCodecCompatibilityReport. Additional public routes: `komorebi_math.api.v1.PortableCodecCompatibilityReport`, `komorebi_math.v1.PortableCodecCompatibilityReport`.

AG-0092 **`PortableCodecContract`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 PortableCodecContract. Additional public routes: `komorebi_math.api.v1.PortableCodecContract`, `komorebi_math.v1.PortableCodecContract`.

AG-0093 **`PortableCodecContractEntry`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 PortableCodecContractEntry. Additional public routes: `komorebi_math.api.v1.PortableCodecContractEntry`, `komorebi_math.v1.PortableCodecContractEntry`.

AG-0099 **`RelationResidual`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.realization`. Stable cards: A.3 RelationResidual. Additional public routes: `komorebi_math.api.v1.RelationResidual`, `komorebi_math.v1.RelationResidual`.

AG-0104 **`residue_synthesize`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.refinement.residue`. Stable cards: A.5 residue_synthesize. Additional public routes: `komorebi_math.api.v1.residue_synthesize`, `komorebi_math.v1.residue_synthesize`.

AG-0105 **`ResidueCoordinates`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.refinement.residue`. Stable cards: A.5 ResidueCoordinates. Additional public routes: `komorebi_math.api.v1.ResidueCoordinates`, `komorebi_math.v1.ResidueCoordinates`.

AG-0106 **`ResourceLimitError`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.exceptions`. Stable cards: A.2 ResourceLimitError. Additional public routes: `komorebi_math.api.v1.ResourceLimitError`, `komorebi_math.v1.ResourceLimitError`.

AG-0107 **`run_stable_semantics_fixture`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.stable_semantics`. Stable cards: A.9 run_stable_semantics_fixture. Additional public routes: `komorebi_math.api.v1.run_stable_semantics_fixture`, `komorebi_math.v1.run_stable_semantics_fixture`.

AG-0109 **`save_portable_codec_contract`**. Strongest listed tier `[STABLE]`. Kinds: `function`. Owners: `komorebi_math.persistence_contract`. Stable cards: A.9 save_portable_codec_contract. Additional public routes: `komorebi_math.api.v1.save_portable_codec_contract`, `komorebi_math.v1.save_portable_codec_contract`.

AG-0115 **`STABLE_API_STABILITY_LEVEL`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 STABLE_API_STABILITY_LEVEL. Additional public routes: `komorebi_math.api.v1.STABLE_API_STABILITY_LEVEL`, `komorebi_math.v1.STABLE_API_STABILITY_LEVEL`.

AG-0116 **`STABLE_PUBLIC_NAMESPACES`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 STABLE_PUBLIC_NAMESPACES. Additional public routes: `komorebi_math.api.v1.STABLE_PUBLIC_NAMESPACES`, `komorebi_math.v1.STABLE_PUBLIC_NAMESPACES`.

AG-0117 **`STABLE_SEMANTICS_SCHEMA`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 STABLE_SEMANTICS_SCHEMA. Additional public routes: `komorebi_math.api.v1.STABLE_SEMANTICS_SCHEMA`, `komorebi_math.v1.STABLE_SEMANTICS_SCHEMA`.

AG-0118 **`STABLE_SEMANTICS_SCHEMA_VERSION`**. Strongest listed tier `[STABLE]`. Kinds: `data`. Owners: `builtins`. Stable cards: A.1 STABLE_SEMANTICS_SCHEMA_VERSION. Additional public routes: `komorebi_math.api.v1.STABLE_SEMANTICS_SCHEMA_VERSION`, `komorebi_math.v1.STABLE_SEMANTICS_SCHEMA_VERSION`.

AG-0119 **`StableContractReport`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.stable_contract`. Stable cards: A.9 StableContractReport. Additional public routes: `komorebi_math.api.v1.StableContractReport`, `komorebi_math.v1.StableContractReport`.

AG-0120 **`StableSemanticCaseResult`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.stable_semantics`. Stable cards: A.9 StableSemanticCaseResult. Additional public routes: `komorebi_math.api.v1.StableSemanticCaseResult`, `komorebi_math.v1.StableSemanticCaseResult`.

AG-0121 **`StableSemanticReport`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.stable_semantics`. Stable cards: A.9 StableSemanticReport. Additional public routes: `komorebi_math.api.v1.StableSemanticReport`, `komorebi_math.v1.StableSemanticReport`.

AG-0125 **`TransferPath`**. Strongest listed tier `[STABLE]`. Kinds: `class`. Owners: `komorebi_math.core.transfer`. Stable cards: A.3 TransferPath. Additional public routes: `komorebi_math.api.v1.TransferPath`, `komorebi_math.v1.TransferPath`.

C.10.5 Beta + Research route groups

AG-0127 **`BEHAVIORAL_GOLDEN_SCHEMA`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.1 BEHAVIORAL_GOLDEN_SCHEMA. Research cards: C.1A BEHAVIORAL_GOLDEN_SCHEMA.

AG-0128 **`BEHAVIORAL_GOLDEN_SCHEMA_VERSION`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.1 BEHAVIORAL_GOLDEN_SCHEMA_VERSION. Research cards: C.1A BEHAVIORAL_GOLDEN_SCHEMA_VERSION.

AG-0129 **`BehavioralGoldenCaseResult`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.golden`. Beta cards: B.1 BehavioralGoldenCaseResult. Research cards: C.1A BehavioralGoldenCaseResult.

AG-0130 **`BehavioralGoldenReport`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.golden`. Beta cards: B.1 BehavioralGoldenReport. Research cards: C.1A BehavioralGoldenReport.

AG-0131 **`BETA_API_STABILITY_LEVEL`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.1 BETA_API_STABILITY_LEVEL. Research cards: C.1A BETA_API_STABILITY_LEVEL.

AG-0132 **`CallableDerivativeProvider`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.derivatives`. Beta cards: B.2 CallableDerivativeProvider. Research cards: C.1E CallableDerivativeProvider, C.5A CallableDerivativeProvider.

AG-0133 **`capture_packet_jet_stream`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 capture_packet_jet_stream. Research cards: C.1E capture_packet_jet_stream, C.5B capture_packet_jet_stream.

AG-0134 **`check_beta_api`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Beta cards: B.1 check_beta_api. Research cards: C.1A check_beta_api.

AG-0135 **`compile_packet_jet_plan`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 compile_packet_jet_plan. Research cards: C.1E compile_packet_jet_plan, C.5B compile_packet_jet_plan.

AG-0136 **`create_beta_api_manifest`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Beta cards: B.1 create_beta_api_manifest. Research cards: C.1A create_beta_api_manifest.

AG-0137 **`DerivativeProvider`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.derivatives`. Beta cards: B.2 DerivativeProvider. Research cards: C.5A DerivativeProvider.

AG-0138 **`estimate_packet_jet_complexity`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 estimate_packet_jet_complexity. Research cards: C.1E estimate_packet_jet_complexity, C.5B estimate_packet_jet_complexity.

AG-0139 **`execute_packet_jet_plan`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 execute_packet_jet_plan. Research cards: C.1E execute_packet_jet_plan, C.5B execute_packet_jet_plan.

AG-0140 **`execute_packet_jets`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 execute_packet_jets. Research cards: C.1E execute_packet_jets, C.5B execute_packet_jets.

AG-0141 **`FiniteDifferenceDerivativeProvider`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.derivatives`. Beta cards: B.2 FiniteDifferenceDerivativeProvider. Research cards: C.1E FiniteDifferenceDerivativeProvider, C.5A FiniteDifferenceDerivativeProvider.

AG-0142 **`load_behavioral_golden_fixture`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.golden`. Beta cards: B.1 load_behavioral_golden_fixture. Research cards: C.1A load_behavioral_golden_fixture.

AG-0143 **`load_beta_api_manifest`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Beta cards: B.1 load_beta_api_manifest. Research cards: C.1A load_beta_api_manifest.

AG-0144 **`load_packet_jet_snapshot_stream`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 load_packet_jet_snapshot_stream. Research cards: C.1E load_packet_jet_snapshot_stream, C.5B load_packet_jet_snapshot_stream.

AG-0145 **`open_packet_jet_snapshot_stream`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 open_packet_jet_snapshot_stream. Research cards: C.5B open_packet_jet_snapshot_stream, C.1E open_packet_jet_snapshot_stream.

AG-0146 **`PACKET_JET_CHUNK_SCHEMA`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.3 PACKET_JET_CHUNK_SCHEMA. Research cards: C.1A PACKET_JET_CHUNK_SCHEMA, C.5B PACKET_JET_CHUNK_SCHEMA.

AG-0147 **`PACKET_JET_CHUNK_SCHEMA_VERSION`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.3 PACKET_JET_CHUNK_SCHEMA_VERSION. Research cards: C.1A PACKET_JET_CHUNK_SCHEMA_VERSION, C.5B PACKET_JET_CHUNK_SCHEMA_VERSION.

AG-0148 **`PACKET_JET_STREAM_SCHEMA`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.3 PACKET_JET_STREAM_SCHEMA. Research cards: C.1A PACKET_JET_STREAM_SCHEMA, C.5B PACKET_JET_STREAM_SCHEMA.

AG-0149 **`PACKET_JET_STREAM_SCHEMA_VERSION`**. Strongest listed tier `[BETA]`. Kinds: `data`. Owners: `builtins`. Beta cards: B.3 PACKET_JET_STREAM_SCHEMA_VERSION. Research cards: C.1A PACKET_JET_STREAM_SCHEMA_VERSION, C.5B PACKET_JET_STREAM_SCHEMA_VERSION.

AG-0150 **`packet_jet_support`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.jets`. Beta cards: B.2 packet_jet_support. Research cards: C.5B packet_jet_support, C.1E packet_jet_support.

AG-0151 **`PacketJet`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.jets`. Beta cards: B.2 PacketJet. Research cards: C.1E PacketJet, C.5B PacketJet.

AG-0152 **`PacketJetAddress`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.jets`. Beta cards: B.2 PacketJetAddress. Research cards: C.5B PacketJetAddress.

AG-0153 **`PacketJetBatchResult`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 PacketJetBatchResult. Research cards: C.1E PacketJetBatchResult, C.5B PacketJetBatchResult.

AG-0154 **`PacketJetCoefficient`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.snapshots`. Beta cards: B.3 PacketJetCoefficient. Research cards: C.5B PacketJetCoefficient.

AG-0155 **`PacketJetComplexityEstimate`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 PacketJetComplexityEstimate. Research cards: C.1E PacketJetComplexityEstimate, C.5B PacketJetComplexityEstimate.

AG-0156 **`PacketJetEvaluation`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 PacketJetEvaluation. Research cards: C.5B PacketJetEvaluation.

AG-0157 `PacketJetExecutionPlan`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 PacketJetExecutionPlan. Research cards: C.1E PacketJetExecutionPlan, C.5B PacketJetExecutionPlan.

AG-0158 `PacketJetFamily`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.jets`. Beta cards: B.2 PacketJetFamily. Research cards: C.1E PacketJetFamily, C.5B PacketJetFamily.

AG-0159 `PacketJetInputGroup`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Beta cards: B.2 PacketJetInputGroup. Research cards: C.5B PacketJetInputGroup.

AG-0160 `PacketJetProfileReport`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 PacketJetProfileReport. Research cards: C.1E PacketJetProfileReport, C.5B PacketJetProfileReport.

AG-0161 `PacketJetSnapshot`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.snapshots`. Beta cards: B.3 PacketJetSnapshot. Research cards: C.1E PacketJetSnapshot, C.5B PacketJetSnapshot.

AG-0162 `PacketJetSnapshotStreamReader`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 PacketJetSnapshotStreamReader. Research cards: C.1E PacketJetSnapshotStreamReader, C.5B PacketJetSnapshotStreamReader.

AG-0163 `PacketJetStreamChunkRecord`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 PacketJetStreamChunkRecord. Research cards: C.1E PacketJetStreamChunkRecord, C.5B PacketJetStreamChunkRecord.

AG-0164 `PacketJetStreamManifest`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 PacketJetStreamManifest. Research cards: C.1E PacketJetStreamManifest, C.5B PacketJetStreamManifest.

AG-0165 `PacketJetStreamSelection`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 PacketJetStreamSelection. Research cards: C.1E PacketJetStreamSelection, C.5B PacketJetStreamSelection.

AG-0166 `PacketJetStreamWriteResult`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 PacketJetStreamWriteResult. Research cards: C.1E PacketJetStreamWriteResult, C.5B PacketJetStreamWriteResult.

AG-0167 `PacketJetSupport`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.jets`. Beta cards: B.2 PacketJetSupport. Research cards: C.5B PacketJetSupport.

AG-0168 `PolynomialDerivativeProvider`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.derivatives`. Beta cards: B.2 PolynomialDerivativeProvider. Research cards: C.1E PolynomialDerivativeProvider, C.5A PolynomialDerivativeProvider.

AG-0169 `profile_operation`. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 profile_operation. Research cards: C.5B profile_operation, C.1E profile_operation.

AG-0170 `profile_packet_jet_runtime`. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 profile_packet_jet_runtime. Research cards: C.5B profile_packet_jet_runtime, C.1E profile_packet_jet_runtime.

AG-0171 `register_portable_codec`. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Beta cards: B.4 register_portable_codec. Research cards: C.6 register_portable_codec, C.1F register_portable_codec.

AG-0172 `register_portable_migration`. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.export.persistence`. Beta cards: B.4 register_portable_migration. Research cards: C.6 register_portable_migration, C.1F register_portable_migration.

AG-0173 `run_behavioral_golden_fixture`. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.golden`. Beta cards: B.1 run_behavioral_golden_fixture. Research cards: C.1A run_behavioral_golden_fixture.

AG-0174 `RuntimeProfileSample`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 RuntimeProfileSample. Research cards: C.1E RuntimeProfileSample, C.5B RuntimeProfileSample.

AG-0175 `RuntimeStageProfile`. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.profiling`. Beta cards: B.2 RuntimeStageProfile. Research cards: C.1E RuntimeStageProfile, C.5B RuntimeStageProfile.

AG-0176 **`save_packet_jet_snapshot_stream`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 save_packet_jet_snapshot_stream. Research cards: C.5B save_packet_jet_snapshot_stream, C.1E save_packet_jet_snapshot_stream.

AG-0177 **`snapshot_packet_jet`**. Strongest listed tier `[BETA]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.snapshots`. Beta cards: B.3 snapshot_packet_jet. Research cards: C.5B snapshot_packet_jet, C.1E snapshot_packet_jet.

AG-0178 **`SparsePolynomialDerivativeProvider`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.sparse`. Beta cards: B.2 SparsePolynomialDerivativeProvider. Research cards: C.1E SparsePolynomialDerivativeProvider, C.5B SparsePolynomialDerivativeProvider.

AG-0179 **`SparseSymmetricTensor`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.sparse`. Beta cards: B.2 SparseSymmetricTensor. Research cards: C.1E SparseSymmetricTensor, C.5B SparseSymmetricTensor.

AG-0180 **`SparseTensorEntry`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.sparse`. Beta cards: B.2 SparseTensorEntry. Research cards: C.1E SparseTensorEntry, C.5B SparseTensorEntry.

AG-0181 **`StreamedPacketJetEvaluation`**. Strongest listed tier `[BETA]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.streaming`. Beta cards: B.3 StreamedPacketJetEvaluation. Research cards: C.1E StreamedPacketJetEvaluation, C.5B StreamedPacketJetEvaluation.

C.10.6 Research route groups

AG-0182 **`AdaptiveFilterResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.adaptive`. Research cards: C.4B AdaptiveFilterResult.

AG-0183 **`AdaptiveMethod`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A AdaptiveMethod.

AG-0184 **`add`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B add.

AG-0185 **`additive_series`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.monoid`. Research cards: C.3A additive_series.

AG-0186 **`affine_basis_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.affine`. Research cards: C.2C affine_basis_transform.

AG-0187 **`affine_interval_change_of_variables`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D affine_interval_change_of_variables.

AG-0188 **`affine_mahler_kernel`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.mahler`. Research cards: C.1G affine_mahler_kernel.

AG-0189 **`affine_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B affine_polynomial.

AG-0190 **`affine_substitution`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B affine_substitution.

AG-0191 **`affine_substitution_coordinate_operator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B affine_substitution_coordinate_operator.

AG-0192 **`affine_substitution_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B affine_substitution_transform.

AG-0193 **`AffineCoordinateTransform`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.affine`. Research cards: C.1C AffineCoordinateTransform, C.2C AffineCoordinateTransform.

AG-0194 **`AlgebraBasisResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.core.algebra`. Research cards: C.1D AlgebraBasisResult.

AG-0195 **`algebraic_function`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A algebraic_function.

AG-0196 **`AlgebraicGFGuess`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A AlgebraicGFGuess.

AG-0197 `all_fubini_orders`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D all_fubini_orders.

AG-0198 `AlternatingForm`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.symplectic`. Research cards: C.1G AlternatingForm.

AG-0199 `analysis_synthesis_integration_certificate`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.adapters`. Research cards: C.1D analysis_synthesis_integration_certificate.

AG-0200 `AnalysisSynthesisCoefficientBlocks`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.frame_algebra`. Research cards: C.1C AnalysisSynthesisCoefficientBlocks, C.2C AnalysisSynthesisCoefficientBlocks.

AG-0201 `AnalysisSynthesisGauge`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.frame_algebra`. Research cards: C.1C AnalysisSynthesisGauge, C.2C AnalysisSynthesisGauge.

AG-0202 `AnalysisSynthesisMap`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.frame_algebra`. Research cards: C.1C AnalysisSynthesisMap, C.2C AnalysisSynthesisMap.

AG-0203 `analytic_mahler_product`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B analytic_mahler_product.

AG-0204 `AnalyticMaskApproximation`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B AnalyticMaskApproximation.

AG-0205 `analyze_recurrence_coordinates`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.1C analyze_recurrence_coordinates, C.2C analyze_recurrence_coordinates.

AG-0206 `antiderivative`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B antiderivative.

AG-0207 `apery_numbers`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A apery_numbers.

AG-0208 `apery_sequence`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.catalog`. Research cards: C.1G apery_sequence.

AG-0209 `API_STABILITY_LEVEL`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A API_STABILITY_LEVEL.

AG-0210 `appell_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.appell`. Research cards: C.1G appell_polynomial.

AG-0211 `appell_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B appell_polynomial.

AG-0212 `appell_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B appell_polynomial_family.

AG-0213 `Apply`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Apply.

AG-0214 `apply`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B apply.

AG-0215 `apply_lowering_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.normalized`. Research cards: C.2A apply_lowering_polynomial.

AG-0216 `apply_recurrence_defect`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C apply_recurrence_defect.

AG-0217 `as_matrix`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A as_matrix.

AG-0218 `as_vector`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A as_vector.

AG-0219 `assign_discrete_precisions`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.precision`. Research cards: C.1D assign_discrete_precisions.

AG-0220 **`AtlasPath`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.2C AtlasPath.

AG-0221 **`AtomicIntegratedDerivativeProvider`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.adapters`. Research cards: C.1D AtomicIntegratedDerivativeProvider.

AG-0222 **`AtomicMeasure`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D AtomicMeasure.

AG-0223 **`audit_apery_supercongruence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_apery_supercongruence.

AG-0224 **`audit_factorial_power_digit_algebra`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.digit_algebra`. Research cards: C.3B audit_factorial_power_digit_algebra.

AG-0225 **`audit_factorial_power_packet_convolution`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_factorial_power_packet_convolution.

AG-0226 **`audit_generalized_bell_digit_sum`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_generalized_bell_digit_sum.

AG-0227 **`audit_generalized_lucas`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_generalized_lucas.

AG-0228 **`audit_partition_lane`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_partition_lane.

AG-0229 **`audit_q_lucas`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_q_lucas.

AG-0230 **`audit_section_cycle`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sections`. Research cards: C.3A audit_section_cycle.

AG-0231 **`audit_touchard`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_touchard.

AG-0232 **`audit_weighted_generalized_bell_digit_sum`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B audit_weighted_generalized_bell_digit_sum.

AG-0233 **`autodiff_provider`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.autodiff`. Research cards: C.1E autodiff_provider, C.1E automatic_derivative_provider, C.5A autodiff_provider, C.5A automatic_derivative_provider.

AG-0234 **`AutomaticDifferentiationProvider`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.autodiff`. Research cards: C.1E AutomaticDifferentiationProvider, C.5A AutomaticDifferentiationProvider.

AG-0235 **`AutomaticSequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.sequences.automatic`. Research cards: C.1G AutomaticSequence.

AG-0236 **`AutomatonCertificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B AutomatonCertificate.

AG-0237 **`AutomorphicCompletionReport`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.completion.gates`. Research cards: C.1G AutomorphicCompletionReport.

AG-0238 **`AutomorphicInductionPlan`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.plans`. Research cards: C.1G AutomorphicInductionPlan.

AG-0239 **`available_ad_frameworks`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.autodiff`. Research cards: C.1E available_ad_frameworks, C.1E available_autodiff_backends, C.5A available_ad_frameworks, C.5A available_autodiff_backends.

AG-0240 **`available_export_formats`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.writers`. Research cards: C.1F available_export_formats, C.6 available_export_formats.

AG-0241 **`available_latex_engines`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.latex`. Research cards: C.1F available_latex_engines, C.6 available_latex_engines.

AG-0242 **`BarycentricCoordinateSystem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.affine`. Research cards: C.2C BarycentricCoordinateSystem.

AG-0243 **`base_digit_sum`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B base_digit_sum.

AG-0244 **`base_digits`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.digit_algebra`. Research cards: C.3B base_digits.

AG-0245 **`basis_from_descriptor`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Research cards: C.3A basis_from_descriptor.

AG-0246 **`basis_from_values`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Research cards: C.3A basis_from_values.

AG-0247 **`BasisCertificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.basis`. Research cards: C.3A BasisCertificate.

AG-0248 **`BasisDescriptor`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.basis`. Research cards: C.3A BasisDescriptor.

AG-0249 **`BayesianUpdate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.dynamics.bayes`. Research cards: C.1G BayesianUpdate.

AG-0250 **`bell_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A bell_numbers.

AG-0251 **`bell_period_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B bell_period_bound.

AG-0252 **`BellDigitReduction`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B BellDigitReduction.

AG-0253 **`BellParityAutomaton`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.bell`. Research cards: C.1F BellParityAutomaton, C.3B BellParityAutomaton.

AG-0254 **`BellResidueAutomaton`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.bell`. Research cards: C.1F BellResidueAutomaton, C.3B BellResidueAutomaton.

AG-0255 **`berlekamp_massey`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B berlekamp_massey.

AG-0256 **`bernoulli_number`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B bernoulli_number.

AG-0257 **`bernoulli_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A bernoulli_numbers.

AG-0258 **`bernoulli_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B bernoulli_polynomial.

AG-0259 **`bernoulli_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B bernoulli_polynomial_family.

AG-0260 **`bernstein_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B bernstein_basis.

AG-0261 **`bernstein_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B bernstein_polynomial.

AG-0262 **`best_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B best_basis.

AG-0263 **`BestBasisResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B BestBasisResult.

AG-0264 **`BETA_PUBLIC_NAMESPACES`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A BETA_PUBLIC_NAMESPACES.

AG-0265 **`bezout_defect_identity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.operators`. Research cards: C.1C bezout_defect_identity, C.2C bezout_defect_identity.

AG-0266 **`BezoutDefectIdentity`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.operators`. Research cards: C.1C BezoutDefectIdentity, C.2C BezoutDefectIdentity.

AG-0267 **`binomial_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B binomial_polynomial.

AG-0268 **`binomial_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B binomial_polynomial_family.

AG-0269 **`binomial_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.1C binomial_transform, C.2A binomial_transform.

AG-0270 **`binomial_valuation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B binomial_valuation.

AG-0271 **`BiquadKind`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A BiquadKind.

AG-0272 **`BlockDiagonalLowRankOperator`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.low_rank`. Research cards: C.1D BlockDiagonalLowRankOperator.

AG-0273 **`BlockDiagonalOperator`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.structured`. Research cards: C.1D BlockDiagonalOperator.

AG-0274 **`borrow_count`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B borrow_count.

AG-0275 **`boundary_functional`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B boundary_functional.

AG-0276 **`BoundaryMode`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A BoundaryMode.

AG-0277 **`BreakpointBandResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B BreakpointBandResult.

AG-0278 **`build_lift_tree`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.1E build_lift_tree, C.5A build_lift_tree.

AG-0279 **`canonical_dual_window`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.windows`. Research cards: C.4A canonical_dual_window.

AG-0280 **`CarryLayerConvolution`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B CarryLayerConvolution.

AG-0281 **`CarryLinearCertificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.normalization`. Research cards: C.3B CarryLinearCertificate.

AG-0282 **`CarryLinearValuation`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.normalization`. Research cards: C.3B CarryLinearValuation.

AG-0283 **`cartier_degree_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B cartier_degree_bound.

AG-0284 **`CartierAutomaton`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B CartierAutomaton.

AG-0285 **`CartierCarryEquivalence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B CartierCarryEquivalence.

AG-0286 **`CartierLinearRepresentation`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B CartierLinearRepresentation.

AG-0287 **`catalan_number`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B catalan_number.

AG-0288 **`catalan_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A catalan_numbers.

AG-0289 **`central_binomial_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A central_binomial_numbers.

AG-0290 `certificate_document`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.report`. Research cards: C.6 certificate_document.

AG-0291 `certified_overlap_add_convolve`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.fft_convolution`. Research cards: C.4A certified_overlap_add_convolve.

AG-0292 `certify_cartier_carry_equivalence`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B certify_cartier_carry_equivalence.

AG-0293 `certify_mahler_functional_equation`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B certify_mahler_functional_equation.

AG-0294 `certify_pointed_subindex_identity`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B certify_pointed_subindex_identity.

AG-0295 `certify_rational_mask_algebraic_relation`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B certify_rational_mask_algebraic_relation.

AG-0296 `certify_state_coordinate_change`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C certify_state_coordinate_change.

AG-0297 `characteristic_closed_form`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A characteristic_closed_form.

AG-0298 `chebyshev_t_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B chebyshev_t_polynomial.

AG-0299 `chebyshev_t_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B chebyshev_t_polynomial_family.

AG-0300 `chebyshev_u_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B chebyshev_u_polynomial.

AG-0301 `chebyshev_u_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B chebyshev_u_polynomial_family.

AG-0302 `check_expression`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B check_expression.

AG-0303 `check_public_api`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A check_public_api.

AG-0304 `CheckedExpression`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B CheckedExpression.

AG-0305 `chinese_remainder_order`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A chinese_remainder_order.

AG-0306 `chinese_remainder_transform`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A chinese_remainder_transform.

AG-0307 `CircuitPacketExpansion`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.circuits`. Research cards: C.1G CircuitPacketExpansion.

AG-0308 `CirculantOperator`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.structured`. Research cards: C.1D CirculantOperator.

AG-0309 `ClaimStatus`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.provenance`. Research cards: C.1A ClaimStatus.

AG-0310 `classical_polynomial_catalog`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.1C classical_polynomial_catalog, C.2B classical_polynomial_catalog.

AG-0311 `classify_carry_linear_valuation`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.normalization`. Research cards: C.3B classify_carry_linear_valuation.

AG-0312 `CliffordStep`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.clifford`. Research cards: C.1G CliffordStep.

AG-0313 `CliffordTower`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.clifford`. Research cards: C.1G CliffordTower.

AG-0314 **`CodeBlock`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Research cards: C.6 CodeBlock.

AG-0315 **`coefficient_packets`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.nonlinear`. Research cards: C.4B coefficient_packets.

AG-0316 **`CoefficientDomain`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A CoefficientDomain.

AG-0317 **`CoefficientPartition`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.frame_algebra`. Research cards: C.1C CoefficientPartition, C.2C CoefficientPartition.

AG-0318 **`CommutingDiagramCheck`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.2C CommutingDiagramCheck.

AG-0319 **`companion_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.1C companion_matrix, C.2C companion_matrix.

AG-0320 **`compare_public_api`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A compare_public_api.

AG-0321 **`CompatiblePropagationReport`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.completion.gates`. Research cards: C.1G CompatiblePropagationReport.

AG-0322 **`compile_cartier_linear_representation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B compile_cartier_linear_representation.

AG-0323 **`compile_digit_cauchy_product`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B compile_digit_cauchy_product.

AG-0324 **`compile_expression`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B compile_expression.

AG-0325 **`compile_finite_mask_carry_plan`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.1F compile_finite_mask_carry_plan, C.3B compile_finite_mask_carry_plan.

AG-0326 **`compile_latex`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.latex`. Research cards: C.1F compile_latex, C.6 compile_latex.

AG-0327 **`compile_rational_mask_automaton`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.1F compile_rational_mask_automaton, C.3B compile_rational_mask_automaton.

AG-0328 **`compile_sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.compiler`. Research cards: C.1G compile_sequence.

AG-0329 **`compile_tree_budget`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.compiler`. Research cards: C.1D compile_tree_budget.

AG-0330 **`compile_tree_lagrangian`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.compiler`. Research cards: C.1D compile_tree_lagrangian.

AG-0331 **`CompiledSequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.sequences.compiler`. Research cards: C.1G CompiledSequence.

AG-0332 **`CompletionGate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.completion.gates`. Research cards: C.1G CompletionGate.

AG-0333 **`Compose`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Compose.

AG-0334 **`compose`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B compose.

AG-0335 **`compose_certificates`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B compose_certificates.

AG-0336 **`compose_functions`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A compose_functions.

AG-0337 **`compose_ordinary_series`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.formal`. Research cards: C.2C compose_ordinary_series.

AG-0338 **`ComposedDerivativeProvider`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.1E ComposedDerivativeProvider, C.5A ComposedDerivativeProvider.

AG-0339 **`CompositeSimpson`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D CompositeSimpson.

AG-0340 **`conditional_projective_limit_completion`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.1E conditional_projective_limit_completion, C.5A conditional_projective_limit_completion.

AG-0341 **`conjugate_gradient`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.krylov`. Research cards: C.1D conjugate_gradient.

AG-0342 **`constant_injection`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B constant_injection.

AG-0343 **`constant_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B constant_polynomial.

AG-0344 **`constraint_closure`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.quantum.constraints`. Research cards: C.1G constraint_closure.

AG-0345 **`contragredient_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A contragredient_transform.

AG-0346 **`controllability_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C controllability_basis.

AG-0347 **`controllability_coordinate_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C controllability_coordinate_transform.

AG-0348 **`controllability_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C controllability_matrix.

AG-0349 **`convert_normalized_coefficients`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.normalized`. Research cards: C.2A convert_normalized_coefficients.

AG-0350 **`convolution_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A convolution_matrix.

AG-0351 **`convolution_output_length`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A convolution_output_length.

AG-0352 **`ConvolutionMode`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A ConvolutionMode.

AG-0353 **`convolve_signal`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A convolve_signal.

AG-0354 **`coordinate_change`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B coordinate_change.

AG-0355 **`coordinate_change_between_recurrences`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.1C coordinate_change_between_recurrences, C.2C coordinate_change_between_recurrences.

AG-0356 **`coordinate_fundamental_theorem`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.coordinates`. Research cards: C.1D coordinate_fundamental_theorem.

AG-0357 **`coordinate_pairing`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A coordinate_pairing.

AG-0358 **`coordinate_transport_identity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.coordinates`. Research cards: C.1D coordinate_transport_identity.

AG-0359 **`CoordinateBudget`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.budget`. Research cards: C.1C CoordinateBudget, C.2C CoordinateBudget.

AG-0360 `CoordinateSpace`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `types`. Research cards: C.1A CoordinateSpace.

AG-0361 `CoordinateSystem`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.1C CoordinateSystem, C.2C CoordinateSystem.

AG-0362 `create_public_api_manifest`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A create_public_api_manifest.

AG-0363 `cross_spectrum`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.spectral`. Research cards: C.4A cross_spectrum.

AG-0364 `CrossSpectrum`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.spectral`. Research cards: C.4A CrossSpectrum.

AG-0365 `crt_many`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.refinement.crt`. Research cards: C.1G crt_many.

AG-0366 `crt_pair`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.refinement.crt`. Research cards: C.1G crt_pair.

AG-0367 `cupy_runtime_status`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.gpu`. Research cards: C.1E cupy_runtime_status, C.5B cupy_runtime_status.

AG-0368 `CuPyDeviceDerivativeProvider`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Research cards: C.1E CuPyDeviceDerivativeProvider, C.5B CuPyDeviceDerivativeProvider.

AG-0369 `CuPyPacketJetExecutor`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Research cards: C.1E CuPyPacketJetExecutor, C.5B CuPyPacketJetExecutor.

AG-0370 `CuPyPacketJetSnapshotExecutor`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.gpu`. Research cards: C.1E CuPyPacketJetSnapshotExecutor, C.1E CuPySnapshotExecutor, C.5B CuPyPacketJetSnapshotExecutor, C.5B CuPySnapshotExecutor.

AG-0371 `CuPyPolynomialDerivativeProvider`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.execution`. Research cards: C.1E CuPyPolynomialDerivativeProvider, C.5B CuPyPolynomialDerivativeProvider.

AG-0372 `CuPyRuntimeStatus`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.gpu`. Research cards: C.1E CuPyRuntimeStatus, C.5B CuPyRuntimeStatus.

AG-0373 `CuPyValidationResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.gpu`. Research cards: C.1E CuPyValidationResult, C.5B CuPyValidationResult.

AG-0374 `custom_exponential`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sections`. Research cards: C.3A custom_exponential.

AG-0375 `custom_recurrence_model`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C custom_recurrence_model.

AG-0376 `custom_section`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sections`. Research cards: C.3A custom_section.

AG-0377 `CustomFunctionSpec`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.functions`. Research cards: C.1F CustomFunctionSpec, C.3A CustomFunctionSpec.

AG-0378 `cyclic_group`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.langlands.finite_image.groups`. Research cards: C.1G cyclic_group.

AG-0379 `cyclic_krylov_matrix`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.2C cyclic_krylov_matrix.

AG-0380 `cyclic_project_coefficients`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.cyclic`. Research cards: C.1G cyclic_project_coefficients.

AG-0381 `cyclic_span`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.seeds`. Research cards: C.1D cyclic_span.

AG-0382 `cyclic_symmetry_projectors`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.quantum.symmetry`. Research cards: C.1G cyclic_symmetry_projectors.

AG-0383 `CyclicDenominator`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.analytic.zeros`. Research cards: C.1G CyclicDenominator.

AG-0384 `CyclicSectionFamily`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.analytic.sections`. Research cards: C.1G CyclicSectionFamily.

AG-0385 `cyclotomic_coboundary`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cyclotomic`. Research cards: C.3B cyclotomic_coboundary.

AG-0386 `CyclotomicCollapse`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.cyclotomic`. Research cards: C.3B CyclotomicCollapse.

AG-0387 `decimate`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A decimate.

AG-0388 `DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `pathlib`. Research cards: C.1G DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE.

AG-0389 `DEFAULT_BETA_API_MANIFEST`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `pathlib`. Research cards: C.1G DEFAULT_BETA_API_MANIFEST.

AG-0390 `DEFAULT_COORDINATE_BUDGET`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `komorebi_math.coordinates.budget`. Research cards: C.2C DEFAULT_COORDINATE_BUDGET.

AG-0391 `DEFAULT_GENERATING_BUDGET`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `komorebi_math.generating.budget`. Research cards: C.3A DEFAULT_GENERATING_BUDGET.

AG-0392 `defect_green_weights`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C defect_green_weights.

AG-0393 `denoising_risk_certificate`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B denoising_risk_certificate.

AG-0394 `denominator`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.sections`. Research cards: C.1G denominator.

AG-0395 `DenseOperator`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.structured`. Research cards: C.1D DenseOperator.

AG-0396 `deprecated`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A deprecated.

AG-0397 `DepthObstructionResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A DepthObstructionResult.

AG-0398 `derivative`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B derivative.

AG-0399 `derivative_coordinate_operator`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B derivative_coordinate_operator.

AG-0400 `derivative_operator_in_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B derivative_operator_in_family.

AG-0401 `DerivativeBound`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D DerivativeBound.

AG-0402 `describe`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.provenance`. Research cards: C.1A describe.

AG-0403 `design_bandpass`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A design_bandpass.

AG-0404 `design_bandstop`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A design_bandstop.

AG-0405 `design_biquad`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recursive`. Research cards: C.4A design_biquad.

AG-0406 `design_fir`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A design_fir.

AG-0407 **`design_highpass`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A design_highpass.

AG-0408 **`design_lowpass`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A design_lowpass.

AG-0409 **`design_resample_filter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A design_resample_filter.

AG-0410 **`detect_piecewise_polynomial_breaks`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B detect_piecewise_polynomial_breaks.

AG-0411 **`determinant`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A determinant.

AG-0412 **`DetrendMode`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A DetrendMode.

AG-0413 **`difference_noise_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B difference_noise_bound.

AG-0414 **`difference_valuation_profile`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B difference_valuation_profile.

AG-0415 **`digit_factorized_normalized_kernel`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.normalization`. Research cards: C.3B digit_factorized_normalized_kernel.

AG-0416 **`digit_reversal_order`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A digit_reversal_order.

AG-0417 **`digit_reversal_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A digit_reversal_transform.

AG-0418 **`digit_unit`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.normalization`. Research cards: C.3B digit_unit.

AG-0419 **`DigitAlgebraAudit`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.digit_algebra`. Research cards: C.3B DigitAlgebraAudit.

AG-0420 **`DigitCauchyProductPlan`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B DigitCauchyProductPlan.

AG-0421 **`DigitKernel`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.digit_algebra`. Research cards: C.3B DigitKernel.

AG-0422 **`direct_packet_rotation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.transport`. Research cards: C.1E direct_packet_rotation, C.5A direct_packet_rotation.

AG-0423 **`direct_sum_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.2C direct_sum_basis.

AG-0424 **`direct_sum_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A direct_sum_transform.

AG-0425 **`DirectionalDerivative`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `collections.abc`. Research cards: C.5A DirectionalDerivative.

AG-0426 **`DirectionalJVP`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.autodiff`. Research cards: C.1E DirectionalJVP, C.5A DirectionalJVP.

AG-0427 **`DirectRotationResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.transport`. Research cards: C.5A DirectRotationResult.

AG-0428 **`dirichlet_convolution`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.monoid`. Research cards: C.3A dirichlet_convolution.

AG-0429 **`discover_block_diagonal_low_rank`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.discovery`. Research cards: C.1D discover_block_diagonal_low_rank.

AG-0430 **`discover_packet_support`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.discovery`. Research cards: C.1D discover_packet_support.

AG-0431 `discrete_cosine_transform`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.numeric`. Research cards: C.2C discrete_cosine_transform.

AG-0432 `discrete_fourier_transform`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.numeric`. Research cards: C.2C discrete_fourier_transform, C.1C discrete_fourier_transform.

AG-0433 `divided_square_packets`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.1E divided_square_packets, C.5A divided_square_packets.

AG-0434 `DividedSquareResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.5A DividedSquareResult.

AG-0435 `divisor_zeta_transform`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A divisor_zeta_transform.

AG-0436 `document_from_data`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.report`. Research cards: C.1F document_from_data, C.6 document_from_data.

AG-0437 `domain_from_descriptor`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A domain_from_descriptor.

AG-0438 `downsample`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A downsample.

AG-0439 `DTypeChoice`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.precision`. Research cards: C.1D DTypeChoice.

AG-0440 `dyadic_sign_diagnostic`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.langlands.global_.dyadic`. Research cards: C.1G dyadic_sign_diagnostic.

AG-0441 `entropy_cost`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B entropy_cost.

AG-0442 `EquivalenceResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B EquivalenceResult.

AG-0443 `equivalent`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B equivalent.

AG-0444 `ErrorGuarantee`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D ErrorGuarantee.

AG-0445 `estimate_positive_packet_1d`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.approximation`. Research cards: C.4B estimate_positive_packet_1d.

AG-0446 `estimate_white_noise_sigma`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B estimate_white_noise_sigma.

AG-0447 `estimated_packet_reconstruct`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B estimated_packet_reconstruct.

AG-0448 `EuclideanTransfer`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.euclidean`. Research cards: C.1G EuclideanTransfer.

AG-0449 `euler_fibonacci_coordinates`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C euler_fibonacci_coordinates, C.1C euler_fibonacci_coordinates.

AG-0450 `euler_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B euler_polynomial.

AG-0451 `euler_polynomial_at_zero`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B euler_polynomial_at_zero.

AG-0452 `euler_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B euler_polynomial_family.

AG-0453 `euler_product_collapse`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B euler_product_collapse.

AG-0454 `euler_product_function`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A euler_product_function.

AG-0455 **`euler_to_fibonacci_coefficient`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B euler_to_fibonacci_coefficient.

AG-0456 **`euler_to_fibonacci_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B euler_to_fibonacci_transform, C.1C euler_to_fibonacci_transform.

AG-0457 **`EulerLocalCoordinates`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.euler`. Research cards: C.1G EulerLocalCoordinates.

AG-0458 **`EulerProductCollapse`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B EulerProductCollapse.

AG-0459 **`evaluate_expression`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B evaluate_expression.

AG-0460 **`evaluation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B evaluation.

AG-0461 **`evaluation_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B evaluation_transform.

AG-0462 **`exact_binding`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B exact_binding.

AG-0463 **`exact_internal_certificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B exact_internal_certificate.

AG-0464 **`exact_map`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B exact_map.

AG-0465 **`exact_value`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B exact_value.

AG-0466 **`ExactAffineMap`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D ExactAffineMap.

AG-0467 **`ExactAnalysisSynthesisMap`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.frame_algebra`. Research cards: C.1C ExactAnalysisSynthesisMap, C.2C ExactAnalysisSynthesisMap.

AG-0468 **`ExactAnalysisSynthesisSystem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.frame_algebra`. Research cards: C.1C ExactAnalysisSynthesisSystem, C.2C ExactAnalysisSynthesisSystem.

AG-0469 **`ExactLinearSystem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A ExactLinearSystem.

AG-0470 **`ExactMapLiteral`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B ExactMapLiteral.

AG-0471 **`exactness_strength`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B exactness_strength.

AG-0472 **`ExactPolynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.polynomial`. Research cards: C.1D ExactPolynomial.

AG-0473 **`ExactQuadratureRule`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.rules`. Research cards: C.1D ExactQuadratureRule.

AG-0474 **`ExactValueLiteral`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B ExactValueLiteral.

AG-0475 **`execute_plan`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B execute_plan.

AG-0476 **`explicit_function`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A explicit_function.

AG-0477 **`exponential_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Research cards: C.2C exponential_basis, C.3A exponential_basis.

AG-0478 **`export_adapters`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.serialization`. Research cards: C.6 export_adapters.

AG-0479 **`export_bundle`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.writers`. Research cards: C.6 export_bundle, C.1F export_bundle.

AG-0480 **`export_data`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.writers`. Research cards: C.6 export_data, C.1F export_data.

AG-0481 **`export_document`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.writers`. Research cards: C.6 export_document, C.1F export_document.

AG-0482 **`export_many`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.writers`. Research cards: C.6 export_many, C.1F export_many.

AG-0483 **`Exportable`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.serialization`. Research cards: C.6 Exportable.

AG-0484 **`ExportBundleResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.writers`. Research cards: C.1F ExportBundleResult, C.6 ExportBundleResult.

AG-0485 **`ExportFormat`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.writers`. Research cards: C.1F ExportFormat, C.6 ExportFormat.

AG-0486 **`ExportOptions`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.writers`. Research cards: C.1F ExportOptions, C.6 ExportOptions.

AG-0487 **`ExportResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.writers`. Research cards: C.1F ExportResult, C.6 ExportResult.

AG-0488 **`Expression`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Expression.

AG-0489 **`expression_digest`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B expression_digest.

AG-0490 **`expression_from_dict`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B expression_from_dict.

AG-0491 **`expression_from_json`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B expression_from_json.

AG-0492 **`EXPRESSION_NODE_VERSION`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A EXPRESSION_NODE_VERSION.

AG-0493 **`EXPRESSION_SCHEMA`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A EXPRESSION_SCHEMA.

AG-0494 **`EXPRESSION_SCHEMA_VERSION`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A EXPRESSION_SCHEMA_VERSION.

AG-0495 **`expression_to_dict`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B expression_to_dict.

AG-0496 **`expression_to_json`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B expression_to_json.

AG-0497 **`EXPRESSION_TYPE_VERSION`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A EXPRESSION_TYPE_VERSION.

AG-0498 **`ExpressionBinding`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B ExpressionBinding.

AG-0499 **`ExpressionBudget`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B ExpressionBudget.

AG-0500 **`ExpressionPlan`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B ExpressionPlan.

AG-0501 **`ExpressionResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B ExpressionResult.

AG-0502 `ExpressionStats`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B ExpressionStats.

AG-0503 `ExpressionType`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `types`. Research cards: C.1A ExpressionType.

AG-0504 `faa_di_bruno`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.1E faa_di_bruno, C.5A faa_di_bruno.

AG-0505 `FaaDiBrunoResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.5A FaaDiBrunoResult.

AG-0506 `FaaDiBrunoTerm`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.5A FaaDiBrunoTerm.

AG-0507 `factorial_power_bell_function`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A factorial_power_bell_function.

AG-0508 `factorial_power_convolution_layers`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B factorial_power_convolution_layers.

AG-0509 `factorial_power_digit_kernel`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.digit_algebra`. Research cards: C.3B factorial_power_digit_kernel.

AG-0510 `factorial_power_support_count`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B factorial_power_support_count.

AG-0511 `factorial_power_support_indices`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B factorial_power_support_indices.

AG-0512 `factorial_valuation`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B factorial_valuation.

AG-0513 `falling_factorial_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B falling_factorial_polynomial.

AG-0514 `falling_factorial_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B falling_factorial_polynomial_family.

AG-0515 `falling_factorial_to_monomial_transform`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A falling_factorial_to_monomial_transform.

AG-0516 `feature`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.registry`. Research cards: C.1G feature.

AG-0517 `FEATURE_KEY`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.5B FEATURE_KEY.

AG-0518 `FEATURE_KEY`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.4A FEATURE_KEY.

AG-0519 `features`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.registry`. Research cards: C.1G features.

AG-0520 `FeatureSpec`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.registry`. Research cards: C.1G FeatureSpec.

AG-0521 `FeatureStatus`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.registry`. Research cards: C.1G FeatureStatus.

AG-0522 `FeshbachReduction`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.dynamics.feshbach`. Research cards: C.1G FeshbachReduction.

AG-0523 `fft_convolve`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.fft_convolution`. Research cards: C.4A fft_convolve.

AG-0524 `fft_lowpass_1d`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.approximation`. Research cards: C.4B fft_lowpass_1d.

AG-0525 `fft_lowpass_2d`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.approximation`. Research cards: C.4B fft_lowpass_2d.

AG-0526 `fibonacci_companion_power`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B fibonacci_companion_power.

AG-0527 `fibonacci_factorial_basis`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Research cards: C.2C fibonacci_factorial_basis, C.3A fibonacci_factorial_basis.

AG-0528 `fibonacci_numbers`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C fibonacci_numbers.

AG-0529 `fibonacci_numbers`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A fibonacci_numbers.

AG-0530 `fibonacci_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B fibonacci_polynomial.

AG-0531 `fibonacci_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B fibonacci_polynomial_family.

AG-0532 `fibonacci_recurrence`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.recurrence`. Research cards: C.1G fibonacci_recurrence.

AG-0533 `fibonacci_recurrence_model`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C fibonacci_recurrence_model.

AG-0534 `fibonacci_sequence`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.catalog`. Research cards: C.1G fibonacci_sequence.

AG-0535 `Figure`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Research cards: C.6 Figure.

AG-0536 `FilterBankReport`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B FilterBankReport.

AG-0537 `FilteredCorrectionProblem`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.1E FilteredCorrectionProblem, C.5A FilteredCorrectionProblem.

AG-0538 `FilteredSpectralSequenceResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A FilteredSpectralSequenceResult.

AG-0539 `FilteredVectorSpace`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.1E FilteredVectorSpace, C.5A FilteredVectorSpace.

AG-0540 `FilterOutput`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.recursive`. Research cards: C.4A FilterOutput.

AG-0541 `finite_difference`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B finite_difference.

AG-0542 `finite_difference`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B finite_difference.

AG-0543 `finite_difference_coordinate_operator`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B finite_difference_coordinate_operator.

AG-0544 `finite_frobenius_separator`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.deformation.companions`. Research cards: C.1G finite_frobenius_separator.

AG-0545 `finite_mask_carry_matrices`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B finite_mask_carry_matrices.

AG-0546 `finite_polyphase_blocks`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A finite_polyphase_blocks, C.4A finite_polyphase_filter_kernels.

AG-0547 `FiniteAbelianGroup`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.1E FiniteAbelianGroup, C.5A FiniteAbelianGroup.

AG-0548 `FiniteCochainComplex`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.deformation.complexes`. Research cards: C.1G FiniteCochainComplex.

AG-0549 `FiniteField`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.finite_fields`. Research cards: C.1G FiniteField.

AG-0550 **`FiniteFieldCoordinateTransform`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.modular`. Research cards: C.1C FiniteFieldCoordinateTransform, C.2A FiniteFieldCoordinateTransform.

AG-0551 **`FiniteFilterBank`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B FiniteFilterBank.

AG-0552 **`FiniteFilteredBranchResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A FiniteFilteredBranchResult.

AG-0553 **`FiniteFilteredCochainComplex`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.1E FiniteFilteredCochainComplex, C.5A FiniteFilteredCochainComplex.

AG-0554 **`FiniteGroup`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.groups`. Research cards: C.1G FiniteGroup.

AG-0555 **`FiniteHeckePackets`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.global_.hecke`. Research cards: C.1G FiniteHeckePackets.

AG-0556 **`FiniteLiftForest`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.deformation.forests`. Research cards: C.1G FiniteLiftForest.

AG-0557 **`FiniteLiftTree`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.1E FiniteLiftTree, C.5A FiniteLiftTree.

AG-0558 **`FiniteMaskCarryPlan`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.1F FiniteMaskCarryPlan, C.3B FiniteMaskCarryPlan, C.3B NormalizedMaskPlan.

AG-0559 **`FiniteMonoidSeries`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.monoid`. Research cards: C.3A FiniteMonoidSeries.

AG-0560 **`FiniteNormalizedSeries`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.finite_series`. Research cards: C.1F FiniteNormalizedSeries, C.3A FiniteNormalizedSeries.

AG-0561 **`FinitePolyphaseKernel`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A FinitePolyphaseKernel, C.4A PolyphaseBlockMatrix.

AG-0562 **`fir_filter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A fir_filter.

AG-0563 **`fir_frequency_response`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A fir_frequency_response.

AG-0564 **`fir_taps_to_series`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.adapters`. Research cards: C.3A fir_taps_to_series.

AG-0565 **`FIRFilter`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A FIRFilter.

AG-0566 **`FIRKind`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A FIRKind.

AG-0567 **`FIRMode`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A FIRMode.

AG-0568 **`FIRSeriesAdapter`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.adapters`. Research cards: C.3A FIRSeriesAdapter.

AG-0569 **`first_frobenius_lift`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B first_frobenius_lift.

AG-0570 **`fixed_packet_leakage`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.quantum.leakage`. Research cards: C.1G fixed_packet_leakage.

AG-0571 **`fractional_power`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.dynamics.fractional`. Research cards: C.1G fractional_power.

AG-0572 **`frame_signal`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A frame_signal.

AG-0573 **`FrameBatch`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A FrameBatch.

AG-0574 **`freeze_custom_function`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.portable`. Research cards: C.1F freeze_custom_function, C.3A freeze_custom_function.

AG-0575 **`FrequencyResponse`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A FrequencyResponse.

AG-0576 **`frobenius_defect_mask`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B frobenius_defect_mask.

AG-0577 **`FrobeniusOrbit`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.tame`. Research cards: C.1G FrobeniusOrbit.

AG-0578 **`FrobeniusSpine`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.deformation.companions`. Research cards: C.1G FrobeniusSpine.

AG-0579 **`from_serializable`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.serialization`. Research cards: C.6 from_serializable, C.1F from_serializable.

AG-0580 **`FrozenGeneratingFunction`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.portable`. Research cards: C.1F FrozenGeneratingFunction, C.3A FrozenGeneratingFunction.

AG-0581 **`fubini_identity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D fubini_identity.

AG-0582 **`FunctionRegistry`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.functions`. Research cards: C.1F FunctionRegistry, C.3A FunctionRegistry.

AG-0583 **`fundamental_theorem`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D fundamental_theorem.

AG-0584 **`FundamentalHolonomy`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.holonomy`. Research cards: C.5A FundamentalHolonomy.

AG-0585 **`gamma_from_impedance`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.smith`. Research cards: C.4B gamma_from_impedance.

AG-0586 **`GateStatus`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.completion.gates`. Research cards: C.1G GateStatus.

AG-0587 **`gauss_sum`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.langlands.local.gauss`. Research cards: C.1G gauss_sum.

AG-0588 **`gaussian_binomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B gaussian_binomial.

AG-0589 **`generalized_bell_digit_reduction`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.bell`. Research cards: C.1F generalized_bell_digit_reduction, C.3B generalized_bell_digit_reduction.

AG-0590 **`generalized_bell_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A generalized_bell_numbers.

AG-0591 **`generalized_bell_parity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B generalized_bell_parity.

AG-0592 **`generalized_bell_polynomials`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A generalized_bell_polynomials.

AG-0593 **`GeneratingBudget`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.budget`. Research cards: C.1F GeneratingBudget, C.3A GeneratingBudget.

AG-0594 **`get_recurrence_model`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C get_recurrence_model, C.1C get_recurrence_model.

AG-0595 **`get_sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.catalog`. Research cards: C.1G get_sequence.

AG-0596 **`get_window`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.windows`. Research cards: C.4A get_window.

AG-0597 **`GradedConvolutionResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.5A GradedConvolutionResult.

AG-0598 **`GradedConvolutionTerm`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.5A GradedConvolutionTerm.

AG-0599 **`GradedPacketOperation`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.1E GradedPacketOperation, C.5A GradedPacketOperation.

AG-0600 **`GradingCertificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.5A GradingCertificate.

AG-0601 **`guess_algebraic_gf`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A guess_algebraic_gf.

AG-0602 **`guess_hypergeometric_ratio`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A guess_hypergeometric_ratio.

AG-0603 **`guess_linear_recurrence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A guess_linear_recurrence.

AG-0604 **`guess_p_recursive`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A guess_p_recursive.

AG-0605 **`guess_quasipolynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A guess_quasipolynomial.

AG-0606 **`haar_analyze`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B haar_analyze.

AG-0607 **`haar_decompose`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B haar_decompose.

AG-0608 **`haar_filter_bank`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B haar_filter_bank.

AG-0609 **`haar_lipschitz_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B haar_lipschitz_bound.

AG-0610 **`haar_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B haar_matrix.

AG-0611 **`haar_packet_analyze`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B haar_packet_analyze.

AG-0612 **`haar_packet_synthesize`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B haar_packet_synthesize.

AG-0613 **`haar_step_coefficient`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B haar_step_coefficient.

AG-0614 **`haar_synthesize`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B haar_synthesize.

AG-0615 **`haar_wavelet_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.numeric`. Research cards: C.2C haar_wavelet_transform.

AG-0616 **`HaarDecomposition`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B HaarDecomposition.

AG-0617 **`HaarFilterBank`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B HaarFilterBank.

AG-0618 **`HaarPacketTree`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.1F HaarPacketTree, C.4B HaarPacketTree.

AG-0619 **`half_shift_distance`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.edge_recovery`. Research cards: C.4B half_shift_distance.

AG-0620 **`Heading`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Research cards: C.6 Heading.

AG-0621 **`HeisenbergModel`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.heisenberg`. Research cards: C.1G HeisenbergModel.

AG-0622 **`hermite_physicists_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B hermite_physicists_polynomial.

AG-0623 **`hermite_physicists_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B hermite_physicists_polynomial_family.

AG-0624 **`hermite_probabilists_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B hermite_probabilists_polynomial.

AG-0625 **`hermite_probabilists_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B hermite_probabilists_polynomial_family.

AG-0626 **`HiddenSolveResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.elimination`. Research cards: C.5A HiddenSolveResult.

AG-0627 **`higher_maurer_cartan_packets`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.1E higher_maurer_cartan_packets, C.5A higher_maurer_cartan_packets.

AG-0628 **`HigherMaurerCartanResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.5A HigherMaurerCartanResult.

AG-0629 **`HilbertObstructionProjector`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.1E HilbertObstructionProjector, C.5A HilbertObstructionProjector.

AG-0630 **`HilbertObstructionResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.5A HilbertObstructionResult.

AG-0631 **`HolonomicRecurrence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.sequences.holonomic`. Research cards: C.1G HolonomicRecurrence.

AG-0632 **`HtmlRenderOptions`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.renderers`. Research cards: C.6 HtmlRenderOptions.

AG-0633 **`HurwitzSeries`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.hurwitz`. Research cards: C.1G HurwitzSeries.

AG-0634 **`hypergeometric_function`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A hypergeometric_function.

AG-0635 **`HypergeometricGuess`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A HypergeometricGuess.

AG-0636 **`identity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B identity.

AG-0637 **`identity_formal_coordinate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.formal`. Research cards: C.2C identity_formal_coordinate.

AG-0638 **`identity_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A identity_matrix.

AG-0639 **`IdentityMap`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B IdentityMap.

AG-0640 **`impedance_from_gamma`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.smith`. Research cards: C.4B impedance_from_gamma.

AG-0641 **`independent_direct_sum_seed_rank`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.seeds`. Research cards: C.1D independent_direct_sum_seed_rank.

AG-0642 **`InducedRepresentation`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.characters`. Research cards: C.1G InducedRepresentation.

AG-0643 **`infer_export_format`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.writers`. Research cards: C.6 infer_export_format.

AG-0644 **`INTEGER_DOMAIN`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A INTEGER_DOMAIN.

AG-0645 **`integer_valuation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B integer_valuation.

AG-0646 **`IntegerDomain`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A IntegerDomain.

AG-0647 **`integral_coordinate_operator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B integral_coordinate_operator.

AG-0648 **`IntegralIdentity`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D IntegralIdentity.

AG-0649 **`IntegralResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D IntegralResult.

AG-0650 **`integrate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D integrate.

AG-0651 **`integrate_derivative_provider`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D integrate_derivative_provider.

AG-0652 **`integrate_formal_series`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.adapters`. Research cards: C.1D integrate_formal_series.

AG-0653 **`integrate_polynomial_coordinates`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.adapters`. Research cards: C.1D integrate_polynomial_coordinates.

AG-0654 **`integrate_polynomial_oriented`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D integrate_polynomial_oriented.

AG-0655 **`integration_by_parts`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D integration_by_parts.

AG-0656 **`IntegrationError`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D IntegrationError.

AG-0657 **`interpolate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A interpolate.

AG-0658 **`interpolation_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B interpolation_transform.

AG-0659 **`intertwiner_space`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.2C intertwiner_space, C.1C intertwiner_space.

AG-0660 **`IntertwinerSpace`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.1C IntertwinerSpace, C.2C IntertwinerSpace.

AG-0661 **`IntertwiningResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.holonomy`. Research cards: C.5A IntertwiningResult.

AG-0662 **`interval_integration`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B interval_integration.

AG-0663 **`IntervalMeasure`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D IntervalMeasure.

AG-0664 **`inverse_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A inverse_matrix.

AG-0665 **`istft`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A istft.

AG-0666 **`jacobsthal_recurrence_model`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C jacobsthal_recurrence_model.

AG-0667 **`JaxDerivativeProvider`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.autodiff`. Research cards: C.1E JaxDerivativeProvider, C.5A JaxDerivativeProvider.

AG-0668 **`JumpDetection`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B JumpDetection.

AG-0669 **`JumpRecoveryResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B JumpRecoveryResult.

AG-0670 **`KatoTransport`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.transport`. Research cards: C.1E KatoTransport, C.5A KatoTransport.

AG-0671 **`KomorebiDeprecationWarning`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.compatibility`. Research cards: C.1A KomorebiDeprecationWarning.

AG-0672 **`kummer_layer_distribution`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B kummer_layer_distribution.

AG-0673 **`KummerLayerDistribution`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B KummerLayerDistribution.

AG-0674 **`labeled_composition_term_count`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.5A labeled_composition_term_count.

AG-0675 **`lagrange_interpolation_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B lagrange_interpolation_basis.

AG-0676 **`laguerre_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B laguerre_polynomial.

AG-0677 **`laguerre_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B laguerre_polynomial_family.

AG-0678 **`lah_number`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A lah_number.

AG-0679 **`latex_escape`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.renderers`. Research cards: C.6 latex_escape.

AG-0680 **`latex_label`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.renderers`. Research cards: C.6 latex_label.

AG-0681 **`LatexCompilation`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.latex`. Research cards: C.6 LatexCompilation.

AG-0682 **`LatexCompileOptions`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.latex`. Research cards: C.1F LatexCompileOptions, C.6 LatexCompileOptions.

AG-0683 **`LatexEngine`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.latex`. Research cards: C.1F LatexEngine, C.6 LatexEngine.

AG-0684 **`LatexRenderOptions`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.renderers`. Research cards: C.1F LatexRenderOptions, C.6 LatexRenderOptions.

AG-0685 **`LatticePacketData`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.refinement.lattices`. Research cards: C.1G LatticePacketData.

AG-0686 **`legendre_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B legendre_polynomial.

AG-0687 **`legendre_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B legendre_polynomial_family.

AG-0688 **`Let`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Let.

AG-0689 **`let`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B let.

AG-0690 **`lfilter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recursive`. Research cards: C.4A lfilter.

AG-0691 **`lift_digit_sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.digit_algebra`. Research cards: C.3B lift_digit_sequence.

AG-0692 **`LiftStepResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.5A LiftStepResult.

AG-0693 **`LiftTreeNode`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.5A LiftTreeNode.

AG-0694 **`LindbladGenerator`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.lindblad`. Research cards: C.1G LindbladGenerator.

AG-0695 **`linear_recurrence_function`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A linear_recurrence_function.

AG-0696 **`LinearCharacter`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.characters`. Research cards: C.1G LinearCharacter.

AG-0697 **`LinearFilter`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.recursive`. Research cards: C.4A LinearFilter.

AG-0698 **`LinearLiftProblem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.1E LinearLiftProblem, C.5A LinearLiftProblem.

AG-0699 **`LinearMapType`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B LinearMapType.

AG-0700 **`LinearObstructionProblem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.obstruction`. Research cards: C.1E LinearObstructionProblem, C.5A LinearObstructionProblem.

AG-0701 **`LinearRealization`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.1C LinearRealization, C.2C LinearRealization.

AG-0702 **`LinearRecurrence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.recurrence`. Research cards: C.1G LinearRecurrence.

AG-0703 **`LinearRecurrenceGuess`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A LinearRecurrenceGuess.

AG-0704 **`LinearRefinementDefect`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.refinement.defects`. Research cards: C.1G LinearRefinementDefect.

AG-0705 **`ListBlock`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Research cards: C.6 ListBlock.

AG-0706 **`lms_filter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.adaptive`. Research cards: C.4B lms_filter.

AG-0707 **`load_coordinate_object`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.portable`. Research cards: C.2C load_coordinate_object, C.1C load_coordinate_object.

AG-0708 **`load_coordinate_record`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.portable`. Research cards: C.2C load_coordinate_record.

AG-0709 **`load_public_api_manifest`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A load_public_api_manifest.

AG-0710 **`load_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.portable`. Research cards: C.2C load_transform.

AG-0711 **`local_normalized_kernel`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.normalization`. Research cards: C.3B local_normalized_kernel.

AG-0712 **`LowRankOperator`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.low_rank`. Research cards: C.1D LowRankOperator.

AG-0713 **`lp_cost`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B lp_cost.

AG-0714 **`lucas_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B lucas_polynomial.

AG-0715 **`lucas_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B lucas_polynomial_family.

AG-0716 **`lucas_recurrence_model`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C lucas_recurrence_model.

AG-0717 **`LyapunovSchmidtDecomposition`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.5A LyapunovSchmidtDecomposition.

AG-0718 **`LyapunovSchmidtPoint`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.5A LyapunovSchmidtPoint.

AG-0719 **`LyapunovSchmidtReduction`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.1E LyapunovSchmidtReduction, C.5A LyapunovSchmidtReduction.

AG-0720 **`mackey_tensor_packets`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.langlands.finite_image.mackey`. Research cards: C.1G mackey_tensor_packets.

AG-0721 **`mahler_coefficients`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B mahler_coefficients.

AG-0722 **`mahler_mask_inverse`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B mahler_mask_inverse, C.1F mahler_mask_inverse.

AG-0723 **`mahler_mask_product`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B mahler_mask_product, C.1F mahler_mask_product.

AG-0724 **`MahlerSeries`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.mahler`. Research cards: C.1G MahlerSeries.

AG-0725 **`majorant_convergence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.1E majorant_convergence, C.5B majorant_convergence.

AG-0726 **`MajorantConvergence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B MajorantConvergence.

AG-0727 **`MarkovLumping`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.dynamics.markov`. Research cards: C.1G MarkovLumping.

AG-0728 **`Matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.2C Matrix.

AG-0729 **`matrix_add`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_add.

AG-0730 **`matrix_chain_multiply`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.planning`. Research cards: C.1B matrix_chain_multiply.

AG-0731 **`matrix_chain_parenthesization`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.planning`. Research cards: C.1B matrix_chain_parenthesization.

AG-0732 **`matrix_chain_plan`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.planning`. Research cards: C.1B matrix_chain_plan.

AG-0733 **`matrix_from_columns`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_from_columns.

AG-0734 **`matrix_multiply`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_multiply.

AG-0735 **`matrix_power`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_power.

AG-0736 **`matrix_rank`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_rank.

AG-0737 **`matrix_shape`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_shape.

AG-0738 **`matrix_subtract`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_subtract.

AG-0739 **`matrix_units`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.algebra`. Research cards: C.1D matrix_units.

AG-0740 **`matrix_vector_multiply`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A matrix_vector_multiply.

AG-0741 **`MatrixChainPlan`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.planning`. Research cards: C.1B MatrixChainPlan.

AG-0742 **`MatrixChainTree`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.planning`. Research cards: C.1B MatrixChainTree.

AG-0743 **`MatrixSemigroup`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.dynamics.semigroups`. Research cards: C.1G MatrixSemigroup.

AG-0744 **`maurer_cartan_packets`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.1E maurer_cartan_packets, C.5A maurer_cartan_packets.

AG-0745 **`MaurerCartanResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.graded`. Research cards: C.5A MaurerCartanResult.

AG-0746 **`Measure`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D Measure.

AG-0747 **`median_absolute_deviation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B median_absolute_deviation.

AG-0748 **`MemoryKernel`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.dynamics.memory`. Research cards: C.1G MemoryKernel.

AG-0749 **`minimal_prefix_period`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B minimal_prefix_period.

AG-0750 **`minimize_cartier_automaton`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B minimize_cartier_automaton.

AG-0751 **`mixed_radix_address`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Research cards: C.4B mixed_radix_address.

AG-0752 **`mobius_integer`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A mobius_integer.

AG-0753 **`modal_coordinate_system`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.numeric`. Research cards: C.2C modal_coordinate_system.

AG-0754 **`ModalCoordinateSystem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.numeric`. Research cards: C.2C ModalCoordinateSystem.

AG-0755 **`ModularLinearSolution`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.5A ModularLinearSolution.

AG-0756 **`ModularMatrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.2C ModularMatrix.

AG-0757 **`ModularVector`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.2C ModularVector.

AG-0758 **`monomial_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B monomial_polynomial_family.

AG-0759 **`monomial_to_falling_factorial_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A monomial_to_falling_factorial_transform.

AG-0760 **`monomial_to_fibonacci_coefficient`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B monomial_to_fibonacci_coefficient.

AG-0761 **`monomial_to_rising_factorial_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A monomial_to_rising_factorial_transform.

AG-0762 **`MonomialAction`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.finite_image.orbits`. Research cards: C.1G MonomialAction.

AG-0763 **`motzkin_sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.catalog`. Research cards: C.1G motzkin_sequence.

AG-0764 **`MovingPacketSystem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.transport`. Research cards: C.1E MovingPacketSystem, C.5A MovingPacketSystem.

AG-0765 **`MultilinearOperation`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `collections.abc`. Research cards: C.1E MultilinearOperation, C.5B MultilinearOperation.

AG-0766 **`multiplication_coordinate_operator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B multiplication_coordinate_operator.

AG-0767 **`multiplicative_order_mod_prime`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B multiplicative_order_mod_prime.

AG-0768 **`multiplicative_series`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.monoid`. Research cards: C.3A multiplicative_series.

AG-0769 **`newton_evaluation_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A newton_evaluation_transform.

AG-0770 **`newton_interpolation_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B newton_interpolation_basis.

AG-0771 **`nlms_filter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.adaptive`. Research cards: C.4B nlms_filter.

AG-0772 **`nonlinear_cupy_available`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.execution`. Research cards: C.5B nonlinear_cupy_available, C.1E nonlinear_cupy_available.

AG-0773 **`nonlinear_shift_filter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.nonlinear`. Research cards: C.4B nonlinear_shift_filter.

AG-0774 **`NonlinearPacketMap`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.coordinates`. Research cards: C.1E NonlinearPacketMap, C.5A NonlinearPacketMap.

AG-0775 **`NonlinearRefinementDefect`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.defects`. Research cards: C.1E NonlinearRefinementDefect, C.5A NonlinearRefinementDefect.

AG-0776 **`NonlinearSchurElimination`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.elimination`. Research cards: C.1E NonlinearSchurElimination, C.5A NonlinearSchurElimination.

AG-0777 **`normal_form_digest`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B normal_form_digest.

AG-0778 **`NormalForm`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B NormalForm.

AG-0779 **`normalization_change_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.normalized`. Research cards: C.2A normalization_change_transform, C.1C normalization_change_transform.

AG-0780 **`normalize_expression`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B normalize_expression.

AG-0781 **`normalized_cyclotomic_expression`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cyclotomic`. Research cards: C.3B normalized_cyclotomic_expression.

AG-0782 **`NormalizedBasis`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.basis`. Research cards: C.1F NormalizedBasis, C.1F WeightedMonomialBasis, C.2C NormalizedBasis, C.3A NormalizedBasis, C.3A NormalizedMonomialBasis, C.3A WeightedMonomialBasis.

AG-0783 **`NormalizedKernelResidue`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B NormalizedKernelResidue.

AG-0784 **`nullspace`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A nullspace.

AG-0785 **`observability_block_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C observability_block_matrix.

AG-0786 **`observability_coordinate_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C observability_coordinate_transform.

AG-0787 **`observability_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.2C observability_matrix, C.1C observability_matrix.

AG-0788 **`ObstructionResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.obstruction`. Research cards: C.5A ObstructionResult.

AG-0789 **`ObstructionSquare`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.obstruction`. Research cards: C.5A ObstructionSquare.

AG-0790 **`one_borrow_count`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B one_borrow_count.

AG-0791 **`operator_change_of_coordinates`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B operator_change_of_coordinates, C.1C operator_change_of_coordinates.

AG-0792 **`operator_commutator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B operator_commutator.

AG-0793 **`operator_matrix_between_families`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B operator_matrix_between_families.

AG-0794 **`OperatorAlgebra`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.core.algebra`. Research cards: C.1D OperatorAlgebra.

AG-0795 **`OperatorMorphism`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.core.morphisms`. Research cards: C.1D OperatorMorphism.

AG-0796 **`ordered_rooted_trees`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B ordered_rooted_trees.

AG-0797 **`ordered_tree_count`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B ordered_tree_count.

AG-0798 **`ordered_trees_with_leaves`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B ordered_trees_with_leaves.

AG-0799 **`OrderedRootedTree`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.1E OrderedRootedTree, C.5B OrderedRootedTree.

AG-0800 **`otsu_threshold`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.approximation`. Research cards: C.4B otsu_threshold.

AG-0801 **`overlap_add`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A overlap_add.

AG-0802 **`overlap_add_certificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.windows`. Research cards: C.4A overlap_add_certificate.

AG-0803 **`overlap_add_convolve`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.fft_convolution`. Research cards: C.4A overlap_add_convolve.

AG-0804 **`overlap_matrix_error`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B overlap_matrix_error.

AG-0805 **`overlap_partition_lp_error`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B overlap_partition_lp_error.

AG-0806 **`overlap_profile`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.windows`. Research cards: C.4A overlap_profile.

AG-0807 **`OverlapAddConvolver`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.fft_convolution`. Research cards: C.4A OverlapAddConvolver.

AG-0808 **`p_adic_valuation_fraction`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B p_adic_valuation_fraction.

AG-0809 **`p_free_orbit`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cyclotomic`. Research cards: C.3B p_free_orbit.

AG-0810 **`packet_energy`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B packet_energy.

AG-0811 **`packet_faa_di_bruno`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.5A packet_faa_di_bruno, C.1E packet_faa_di_bruno.

AG-0812 `packet_jet_benchmark_contract`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.execution`. Research cards: C.5B packet_jet_benchmark_contract, C.1E packet_jet_benchmark_contract.

AG-0813 `packet_product`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.nonlinear`. Research cards: C.4B packet_product.

AG-0814 `packet_taylor`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.jets`. Research cards: C.5B packet_taylor, C.1E packet_taylor.

AG-0815 `packet_tree_reconstruction`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B packet_tree_reconstruction, C.1E packet_tree_reconstruction.

AG-0816 `PacketDerivativeResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.transport`. Research cards: C.5A PacketDerivativeResult.

AG-0817 `PacketEstimate1D`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.approximation`. Research cards: C.4B PacketEstimate1D.

AG-0818 `PacketIdentity`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.series`. Research cards: C.3A PacketIdentity.

AG-0819 `PacketIR`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.ir`. Research cards: C.1D PacketIR.

AG-0820 `PacketLabel`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `types`. Research cards: C.5B PacketLabel.

AG-0821 `PacketLayout`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.layout`. Research cards: C.1D PacketLayout.

AG-0822 `PacketMorphism`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.core.morphisms`. Research cards: C.1D PacketMorphism.

AG-0823 `PacketPath`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `types`. Research cards: C.4A PacketPath.

AG-0824 `PacketTaylorResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.jets`. Research cards: C.5B PacketTaylorResult.

AG-0825 `PacketTreeResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B PacketTreeResult.

AG-0826 `padic_valuation`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.valuation`. Research cards: C.1G padic_valuation.

AG-0827 `padovan_recurrence_model`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C padovan_recurrence_model.

AG-0828 `pairing_invariant`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A pairing_invariant.

AG-0829 `parseval_certificate`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.spectral`. Research cards: C.4A parseval_certificate.

AG-0830 `Partition`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.5A Partition.

AG-0831 `partition_numbers`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A partition_numbers.

AG-0832 `partition_sequence`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.catalog`. Research cards: C.1G partition_sequence.

AG-0833 `PatchingSupportReport`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.global_.patching`. Research cards: C.1G PatchingSupportReport.

AG-0834 `pell_polynomial`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B pell_polynomial.

AG-0835 `pell_polynomial_family`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B pell_polynomial_family.

AG-0836 `pell_recurrence_model`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C pell_recurrence_model.

AG-0837 **`periodic_five_three_lifting`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B periodic_five_three_lifting.

AG-0838 **`periodic_laplacian`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.quantum.spectral`. Research cards: C.1G periodic_laplacian.

AG-0839 **`PeriodicFilterBank`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.1F PeriodicFilterBank, C.4B PeriodicFilterBank.

AG-0840 **`PeriodicLiftingScheme`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filterbanks`. Research cards: C.4B PeriodicLiftingScheme.

AG-0841 **`periodogram`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.spectral`. Research cards: C.4A periodogram.

AG-0842 **`permutation_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.2C permutation_transform.

AG-0843 **`phase_mobius`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.smith`. Research cards: C.4B phase_mobius.

AG-0844 **`PhaseTypeSurvival`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.dynamics.survival`. Research cards: C.1G PhaseTypeSurvival.

AG-0845 **`PlanInstruction`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B PlanInstruction.

AG-0846 **`pochhammer_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Research cards: C.3A pochhammer_basis.

AG-0847 **`pointed_subindex_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B pointed_subindex_polynomial.

AG-0848 **`PointedSubindexCertificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B PointedSubindexCertificate.

AG-0849 **`Polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.2C Polynomial.

AG-0850 **`polynomial_add`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B polynomial_add.

AG-0851 **`polynomial_cartier`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B polynomial_cartier.

AG-0852 **`polynomial_compose_affine`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B polynomial_compose_affine.

AG-0853 **`polynomial_derivative`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B polynomial_derivative.

AG-0854 **`polynomial_derivative_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.quadrature`. Research cards: C.1D polynomial_derivative_bound.

AG-0855 **`polynomial_evaluate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B polynomial_evaluate.

AG-0856 **`polynomial_extended_gcd`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.operators`. Research cards: C.2C polynomial_extended_gcd.

AG-0857 **`polynomial_from_family_coordinates`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.adapters`. Research cards: C.1D polynomial_from_family_coordinates.

AG-0858 **`polynomial_from_formal_series`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.adapters`. Research cards: C.1D polynomial_from_formal_series.

AG-0859 **`polynomial_integral`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B polynomial_integral.

AG-0860 **`polynomial_integration_covector`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.coordinates`. Research cards: C.1D polynomial_integration_covector.

AG-0861 `polynomial_mask_coboundary`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B polynomial_mask_coboundary.

AG-0862 `polynomial_multiply`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B polynomial_multiply.

AG-0863 `polynomial_multiply_mod`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B polynomial_multiply_mod.

AG-0864 `polynomial_operator`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B polynomial_operator.

AG-0865 `polynomial_power_mod`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B polynomial_power_mod.

AG-0866 `polynomial_scale`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B polynomial_scale.

AG-0867 `polynomial_shift`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B polynomial_shift.

AG-0868 `polynomial_subtract`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B polynomial_subtract.

AG-0869 `PolynomialCoboundaryResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B PolynomialCoboundaryResult.

AG-0870 `PolynomialCoordinateOperator`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.1C PolynomialCoordinateOperator, C.2B PolynomialCoordinateOperator.

AG-0871 `PolynomialCoordinateSpace`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B PolynomialCoordinateSpace.

AG-0872 `PolynomialFamily`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.1C PolynomialFamily, C.2B PolynomialFamily.

AG-0873 `PolynomialFamilyCatalog`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B PolynomialFamilyCatalog.

AG-0874 `PolynomialFixedPointProblem`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.1E PolynomialFixedPointProblem, C.5B PolynomialFixedPointProblem.

AG-0875 `PolynomialIntegrationCovector`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.coordinates`. Research cards: C.1D PolynomialIntegrationCovector.

AG-0876 `PolynomialLiftProblem`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.1E PolynomialLiftProblem, C.5A PolynomialLiftProblem.

AG-0877 `PolynomialPrimitive`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B PolynomialPrimitive.

AG-0878 `polyphase_convolution`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A polyphase_convolution.

AG-0879 `polyphase_filter_kernels`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Research cards: C.4B polyphase_filter_kernels.

AG-0880 `PolyphaseConvolution`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.convolution`. Research cards: C.4A PolyphaseConvolution.

AG-0881 `PolyphaseKernel`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.polyphase`. Research cards: C.4B PolyphaseKernel.

AG-0882 `positive_zero_string`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.zeros`. Research cards: C.1G positive_zero_string.

AG-0883 `PowerSpectrum`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.spectral`. Research cards: C.4A PowerSpectrum.

AG-0884 `PRecursiveGuess`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A PRecursiveGuess.

AG-0885 **`PresentedModule`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.deformation.support`. Research cards: C.1G PresentedModule.

AG-0886 **`prime_valuation_packets`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.monoid`. Research cards: C.3A prime_valuation_packets.

AG-0887 **`PrimeFieldDomain`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A PrimeFieldDomain.

AG-0888 **`PrimePowerBinomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B PrimePowerBinomial.

AG-0889 **`PrimePowerKernelCompiler`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.1F PrimePowerKernelCompiler, C.3B PrimePowerKernelCompiler.

AG-0890 **`PrimePowerUnitCompiler`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.padic_units`. Research cards: C.3B PrimePowerUnitCompiler.

AG-0891 **`primitive_certificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B primitive_certificate.

AG-0892 **`primitive_matrix_equal`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B primitive_matrix_equal.

AG-0893 **`PrimitiveKind`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.polynomial`. Research cards: C.1B PrimitiveKind.

AG-0894 **`product_measure`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D product_measure.

AG-0895 **`ProductMeasure`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D ProductMeasure.

AG-0896 **`ProjectiveIntertwinerEnvelope`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.envelopes`. Research cards: C.1G ProjectiveIntertwinerEnvelope.

AG-0897 **`ProjectiveLimitRecord`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A ProjectiveLimitRecord.

AG-0898 **`ProjectiveMultiplicityPacket`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.ramification.towers`. Research cards: C.1G ProjectiveMultiplicityPacket.

AG-0899 **`ProvenanceRecord`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.provenance`. Research cards: C.1A ProvenanceRecord.

AG-0900 **`PrunedPacketCoefficients`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B PrunedPacketCoefficients.

AG-0901 **`pushforward_identity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.identities`. Research cards: C.1D pushforward_identity.

AG-0902 **`pushforward_measure`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D pushforward_measure.

AG-0903 **`PushforwardMeasure`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.measures`. Research cards: C.1D PushforwardMeasure.

AG-0904 **`q_binomial_support`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B q_binomial_support.

AG-0905 **`q_binomial_valuation_decomposition`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B q_binomial_valuation_decomposition, C.1F q_binomial_valuation_decomposition.

AG-0906 **`q_binomial_valuation_direct`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B q_binomial_valuation_direct.

AG-0907 **`q_factorial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B q_factorial.

AG-0908 `q_factorial_basis`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.basis`. Research cards: C.3A q_factorial_basis.

AG-0909 `q_integer`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B q_integer.

AG-0910 `QKummerDecomposition`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.q_kummer`. Research cards: C.3B QKummerDecomposition.

AG-0911 `quadratic_catalan_majorant`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B quadratic_catalan_majorant, C.1E quadratic_catalan_majorant.

AG-0912 `QuadraticRefinement`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.symplectic`. Research cards: C.1G QuadraticRefinement.

AG-0913 `QuadratureExactness`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.rules`. Research cards: C.1D QuadratureExactness.

AG-0914 `QuadratureRule`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.integration.rules`. Research cards: C.1D QuadratureRule.

AG-0915 `QuantumChannel`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.channels`. Research cards: C.1G QuantumChannel.

AG-0916 `QuantumCode`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.error_correction`. Research cards: C.1G QuantumCode.

AG-0917 `QuantumFeshbachReduction`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.effective`. Research cards: C.1G QuantumFeshbachReduction.

AG-0918 `QuantumSeedSystem`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.quantum.seeds`. Research cards: C.1G QuantumSeedSystem.

AG-0919 `QuasiPolynomialGuess`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A QuasiPolynomialGuess.

AG-0920 `RamificationCliffordTower`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.ramification.towers`. Research cards: C.1G RamificationCliffordTower.

AG-0921 `RamificationStage`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.ramification.towers`. Research cards: C.1G RamificationStage.

AG-0922 `RATIONAL_DOMAIN`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A RATIONAL_DOMAIN.

AG-0923 `rational_function`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A rational_function.

AG-0924 `rational_gf_from_recurrence`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.closed_forms`. Research cards: C.3A rational_gf_from_recurrence.

AG-0925 `rational_mask_coefficients_mod_prime`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cartier`. Research cards: C.3B rational_mask_coefficients_mod_prime.

AG-0926 `RATIONAL_SPACE`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `komorebi_math.expression.model`. Research cards: C.1B RATIONAL_SPACE.

AG-0927 `RationalDomain`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A RationalDomain.

AG-0928 `RationalMaskAlgebraicCertificate`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B RationalMaskAlgebraicCertificate.

AG-0929 `RationalResamplingPlan`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A RationalResamplingPlan.

AG-0930 `RationalSpace`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B RationalSpace.

AG-0931 `RawLatex`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Research cards: C.6 RawLatex.

AG-0932 **realization_defect**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.realization. Research cards: C.2C realization_defect.

AG-0933 **reciprocal_coefficients**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.analytic.reciprocal. Research cards: C.1G reciprocal_coefficients.

AG-0934 **recompress_factors**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.algorithms.low_rank. Research cards: C.1D recompress_factors.

AG-0935 **reconstruction_error**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.signals.filterbanks. Research cards: C.4B reconstruction_error.

AG-0936 **recover_initial_state**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.realization. Research cards: C.2C recover_initial_state, C.1C recover_initial_state.

AG-0937 **recover_jumps_subgaussian**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.signals.recovery. Research cards: C.4B recover_jumps_subgaussian.

AG-0938 **recover_separated_jumps**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.signals.recovery. Research cards: C.1F recover_separated_jumps, C.4B recover_separated_jumps.

AG-0939 **recover_vector_jumps**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.signals.edge_recovery. Research cards: C.4B recover_vector_jumps.

AG-0940 **recover_vector_jumps_subgaussian**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.signals.edge_recovery. Research cards: C.4B recover_vector_jumps_subgaussian.

AG-0941 **recurrence_analysis_transform**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.recurrence. Research cards: C.2C recurrence_analysis_transform.

AG-0942 **recurrence_model_catalog**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.families. Research cards: C.2C recurrence_model_catalog, C.1C recurrence_model_catalog.

AG-0943 **recurrence_polynomial**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.recurrence. Research cards: C.2C recurrence_polynomial.

AG-0944 **recurrence_synthesis_transform**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.recurrence. Research cards: C.2C recurrence_synthesis_transform.

AG-0945 **RecurrenceCoordinateRecord**. Strongest listed tier [RESEARCH]. Kinds: class. Owners: komorebi_math.coordinates.recurrence. Research cards: C.1C RecurrenceCoordinateRecord, C.2C RecurrenceCoordinateRecord.

AG-0946 **RecurrenceLike**. Strongest listed tier [RESEARCH]. Kinds: data. Owners: typing. Research cards: C.2C RecurrenceLike.

AG-0947 **RecurrenceModel**. Strongest listed tier [RESEARCH]. Kinds: class. Owners: komorebi_math.coordinates.families. Research cards: C.1C RecurrenceModel, C.2C RecurrenceModel.

AG-0948 **reduce_exact_transform_mod_prime**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.modular. Research cards: C.2A reduce_exact_transform_mod_prime.

AG-0949 **register_coordinate_codecs**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.coordinates.portable. Research cards: C.2C register_coordinate_codecs.

AG-0950 **register_export_adapter**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.export.serialization. Research cards: C.6 register_export_adapter.

AG-0951 **register_generating_codecs**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.generating.portable. Research cards: C.3A register_generating_codecs.

AG-0952 **render_html**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.export.renderers. Research cards: C.6 render_html.

AG-0953 **render_text**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.export.renderers. Research cards: C.6 render_text.

AG-0954 **replay**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.expression.polynomial. Research cards: C.1B replay, C.1B replay_matrix.

AG-0955 **require**. Strongest listed tier [RESEARCH]. Kinds: function. Owners: komorebi_math.nonlinear. Research cards: C.5B require.

AG-0956 **`resample_poly`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A resample_poly.

AG-0957 **`resample_poly_result`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A resample_poly_result.

AG-0958 **`resampled_length`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A resampled_length.

AG-0959 **`ResamplingResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A ResamplingResult.

AG-0960 **`residue_class_order`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A residue_class_order.

AG-0961 **`residue_class_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A residue_class_transform, C.1C residue_class_transform.

AG-0962 **`residue_packet_system`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.refinement.residue`. Research cards: C.1G residue_packet_system.

AG-0963 **`ResidueRingDomain`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A ResidueRingDomain.

AG-0964 **`resolve_latex_engine`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.latex`. Research cards: C.6 resolve_latex_engine.

AG-0965 **`retained_packet_reconstruct`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.1F retained_packet_reconstruct, C.4B retained_packet_reconstruct.

AG-0966 **`retained_packet_reconstruction`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B retained_packet_reconstruction.

AG-0967 **`RetainedPacketReconstruction`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B RetainedPacketReconstruction, C.4B RetainedPacketResult.

AG-0968 **`RewriteStep`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B RewriteStep.

AG-0969 **`RightInverseCorrectionProblem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.1E RightInverseCorrectionProblem, C.5A RightInverseCorrectionProblem.

AG-0970 **`RightInverseCorrectionResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.correction`. Research cards: C.5A RightInverseCorrectionResult.

AG-0971 **`rising_factorial_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B rising_factorial_polynomial.

AG-0972 **`rising_factorial_polynomial_family`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.classical`. Research cards: C.2B rising_factorial_polynomial_family.

AG-0973 **`rising_factorial_to_monomial_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A rising_factorial_to_monomial_transform.

AG-0974 **`rising_to_falling_factorial_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A rising_to_falling_factorial_transform.

AG-0975 **`rls_filter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.adaptive`. Research cards: C.4B rls_filter.

AG-0976 **`root_filter_value`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sections`. Research cards: C.3A root_filter_value.

AG-0977 **`rref`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A rref.

AG-0978 **`save_coordinate_object`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.portable`. Research cards: C.2C save_coordinate_object, C.1C save_coordinate_object.

AG-0979 **`save_coordinate_record`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.portable`. Research cards: C.2C save_coordinate_record.

AG-0980 **`save_public_api_manifest`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A save_public_api_manifest.

AG-0981 **`save_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.portable`. Research cards: C.2C save_transform.

AG-0982 **`Scalar`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `types`. Research cards: C.2C Scalar.

AG-0983 **`scalar_region_error`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B scalar_region_error.

AG-0984 **`scalar_region_lp_error`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B scalar_region_lp_error.

AG-0985 **`Scale`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Scale.

AG-0986 **`scale`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B scale.

AG-0987 **`scaling_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.2C scaling_transform.

AG-0988 **`scan_residue_lanes`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B scan_residue_lanes.

AG-0989 **`schedule_unlimited`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.algorithms.scheduling`. Research cards: C.1D schedule_unlimited.

AG-0990 **`SchurDerivativeResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.elimination`. Research cards: C.5A SchurDerivativeResult.

AG-0991 **`SchurSecondDerivativeResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.elimination`. Research cards: C.5A SchurSecondDerivativeResult.

AG-0992 **`search_decimation_relation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.congruences`. Research cards: C.3B search_decimation_relation.

AG-0993 **`secant_euler_from_fibonacci_coordinates`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.polynomials`. Research cards: C.2B secant_euler_from_fibonacci_coordinates.

AG-0994 **`SectionCycleAudit`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.sections`. Research cards: C.3A SectionCycleAudit.

AG-0995 **`SeedMorphism`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.core.morphisms`. Research cards: C.1D SeedMorphism.

AG-0996 **`semisimple_seed_rank`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.seeds`. Research cards: C.1D semisimple_seed_rank.

AG-0997 **`Sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.sequences.base`. Research cards: C.1G Sequence.

AG-0998 **`sequence_coordinates_between_models`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C sequence_coordinates_between_models.

AG-0999 **`sequence_document`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.report`. Research cards: C.6 sequence_document, C.1F sequence_document.

AG-1000 **`series_to_fir_adapter`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.adapters`. Research cards: C.3A series_to_fir_adapter.

AG-1001 **`series_to_fir_taps`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.adapters`. Research cards: C.3A series_to_fir_taps.

AG-1002 **`SeriesTransferCertificate`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.finite_series`. Research cards: C.3A SeriesTransferCertificate.

AG-1003 **`set_partitions`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.5A set_partitions.

AG-1004 **`shannon_entropy_cost`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.wavelets`. Research cards: C.4B shannon_entropy_cost.

AG-1005 **`shared_direct_sum_seed_bounds`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.seeds`. Research cards: C.1D shared_direct_sum_seed_bounds.

AG-1006 **`ShiftPolynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.operators`. Research cards: C.1C ShiftPolynomial, C.2C ShiftPolynomial.

AG-1007 **`signed_euler_number`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.arithmetic.euler`. Research cards: C.1G signed_euler_number.

AG-1008 **`signed_euler_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A signed_euler_numbers.

AG-1009 **`signed_secant_euler_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C signed_secant_euler_numbers.

AG-1010 **`signed_section`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.sections`. Research cards: C.1G signed_section.

AG-1011 **`similarity_from_cyclic_vectors`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.2C similarity_from_cyclic_vectors.

AG-1012 **`SimplificationResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B SimplificationResult.

AG-1013 **`simplify_expression`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.engine`. Research cards: C.1B simplify_expression.

AG-1014 **`single_operator_seed_rank`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.seeds`. Research cards: C.1D single_operator_seed_rank.

AG-1015 **`SingularPacket1D`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.1F SingularPacket1D, C.4B SingularPacket1D.

AG-1016 **`siso_state_space`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C siso_state_space.

AG-1017 **`smith_sensitivity`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.smith`. Research cards: C.4B smith_sensitivity.

AG-1018 **`SmithCongruenceProblem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.refinement.smith`. Research cards: C.1G SmithCongruenceProblem.

AG-1019 **`smooth_haar_coefficient_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.edge_recovery`. Research cards: C.4B smooth_haar_coefficient_bound.

AG-1020 **`solve_linear_system`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A solve_linear_system.

AG-1021 **`solve_mod_prime`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.lifting`. Research cards: C.5A solve_mod_prime, C.1E solve_mod_prime.

AG-1022 **`solve_polynomial_coboundary`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B solve_polynomial_coboundary.

AG-1023 **`sorted_coordinate_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A sorted_coordinate_transform.

AG-1024 **`spectral_dimension`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.quantum.spectral`. Research cards: C.1G spectral_dimension.

AG-1025 **`SpectralAverage`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A SpectralAverage.

AG-1026 **`SpectralScaling`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A SpectralScaling.

AG-1027 **`SpectralSequenceEntry`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A SpectralSequenceEntry.

AG-1028 `SpectralSequencePage`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A SpectralSequencePage.

AG-1029 `spectrogram`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A spectrogram.

AG-1030 `SpectrogramResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A SpectrogramResult.

AG-1031 `SpectrogramScaling`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A SpectrogramScaling.

AG-1032 `split_mixed_radix_address`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.polyphase`. Research cards: C.4B split_mixed_radix_address.

AG-1033 `STAGES`. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.1A STAGES.

AG-1034 `StageSpec`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.unified`. Research cards: C.1G StageSpec.

AG-1035 `StandardWindow`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.standard_windows`. Research cards: C.1G StandardWindow.

AG-1036 `StateRecovery`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.realization`. Research cards: C.1C StateRecovery, C.2C StateRecovery.

AG-1037 `StateSpaceCoordinateCertificate`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.2C StateSpaceCoordinateCertificate.

AG-1038 `StateSpaceModel`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.coordinates.state_space`. Research cards: C.1C StateSpaceModel, C.2C StateSpaceModel.

AG-1039 `status`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear`. Research cards: C.5A status.

AG-1040 `status`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals`. Research cards: C.4A status.

AG-1041 `step_haar_coefficient`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.edge_recovery`. Research cards: C.4B step_haar_coefficient.

AG-1042 `step_location_lp_error`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B step_location_lp_error.

AG-1043 `stft`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A stft.

AG-1044 `STFTResult`. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.time_frequency`. Research cards: C.4A STFTResult.

AG-1045 `stirling_first_signed`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A stirling_first_signed.

AG-1046 `stirling_first_unsigned`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A stirling_first_unsigned.

AG-1047 `stirling_second`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A stirling_second.

AG-1048 `stirling_second`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.composition`. Research cards: C.5A stirling_second.

AG-1049 `stream_fir_filter`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A stream_fir_filter.

AG-1050 `stream_lfilter`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recursive`. Research cards: C.4A stream_lfilter.

AG-1051 `stream_stft`. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.streaming`. Research cards: C.4A stream_stft.

AG-1052 **`StreamingFIR`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.filtering`. Research cards: C.4A StreamingFIR.

AG-1053 **`StreamingLinearFilter`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.recursive`. Research cards: C.4A StreamingLinearFilter.

AG-1054 **`StreamingSTFT`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.streaming`. Research cards: C.4A StreamingSTFT.

AG-1055 **`StreamingSTFTBatch`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.streaming`. Research cards: C.4A StreamingSTFTBatch.

AG-1056 **`subgaussian_noise_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.recovery`. Research cards: C.4B subgaussian_noise_bound.

AG-1057 **`subset_zeta_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A subset_zeta_transform.

AG-1058 **`Sum`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Sum.

AG-1059 **`SupportComparison`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.global_.hecke`. Research cards: C.1G SupportComparison.

AG-1060 **`SupportPreorder`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.core.graphs`. Research cards: C.1D SupportPreorder.

AG-1061 **`sure_threshold`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B sure_threshold.

AG-1062 **`Symbol`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B Symbol.

AG-1063 **`symbol`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B symbol.

AG-1064 **`SympyDerivativeProvider`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.derivatives`. Research cards: C.1E SympyDerivativeProvider, C.5A SympyDerivativeProvider.

AG-1065 **`synthesize_recurrence_coordinates`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C synthesize_recurrence_coordinates.

AG-1066 **`Table`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.export.model`. Research cards: C.1F Table, C.6 Table.

AG-1067 **`table_rows`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.serialization`. Research cards: C.6 table_rows.

AG-1068 **`TameWeilPacket`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.langlands.local.tame`. Research cards: C.1G TameWeilPacket.

AG-1069 **`Task`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.scheduling`. Research cards: C.1D Task.

AG-1070 **`tensor_axis_permutation_order`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A tensor_axis_permutation_order.

AG-1071 **`tensor_axis_permutation_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.packet`. Research cards: C.2A tensor_axis_permutation_transform.

AG-1072 **`tensor_coordinate_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A tensor_coordinate_transform, C.1C tensor_coordinate_transform.

AG-1073 **`tensor_product_basis`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.basis`. Research cards: C.2C tensor_product_basis.

AG-1074 **`tensor_product_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A tensor_product_transform.

AG-1075 **`tensor_seed_rank_upper_bound`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.core.seeds`. Research cards: C.1D tensor_seed_rank_upper_bound.

AG-1076 **`then`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B then.

AG-1077 **`theta_polynomial`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.appell`. Research cards: C.1G theta_polynomial.

AG-1078 **`threshold_coefficients`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B threshold_coefficients.

AG-1079 **`ThresholdMode`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A ThresholdMode.

AG-1080 **`ThresholdRule`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A ThresholdRule.

AG-1081 **`thue_morse_sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.sequences.catalog`. Research cards: C.1G thue_morse_sequence.

AG-1082 **`to_serializable`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.export.serialization`. Research cards: C.6 to_serializable, C.1F to_serializable.

AG-1083 **`TorchDerivativeProvider`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.autodiff`. Research cards: C.1E TorchDerivativeProvider, C.5A TorchDerivativeProvider.

AG-1084 **`transfer_section`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.sections`. Research cards: C.1G transfer_section.

AG-1085 **`transfer_tangent`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.analytic.reciprocal`. Research cards: C.1G transfer_tangent.

AG-1086 **`transform_sequence`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.combinatorial`. Research cards: C.2A transform_sequence.

AG-1087 **`translation_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.affine`. Research cards: C.2C translation_transform.

AG-1088 **`transport_bilinear_form`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A transport_bilinear_form.

AG-1089 **`transport_covector`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A transport_covector.

AG-1090 **`transport_operator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A transport_operator.

AG-1091 **`transport_polynomial_operator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.calculus`. Research cards: C.2B transport_polynomial_operator.

AG-1092 **`transport_rectangular_operator`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A transport_rectangular_operator.

AG-1093 **`transport_tensor_components`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.tensor`. Research cards: C.2A transport_tensor_components.

AG-1094 **`TransportEdge`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.holonomy`. Research cards: C.1E TransportEdge, C.5A TransportEdge.

AG-1095 **`TransportGraph`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.holonomy`. Research cards: C.1E TransportGraph, C.5A TransportGraph.

AG-1096 **`TransportRefinementResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.transport`. Research cards: C.5A TransportRefinementResult.

AG-1097 **`transpose`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A transpose.

AG-1098 **`TreeExpansionResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B TreeExpansionResult.

AG-1099 **`TreeNode`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.compiler`. Research cards: C.1D TreeNode.

AG-1100 **`TreeTerm`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.nonlinear.trees`. Research cards: C.5B TreeTerm.

AG-1101 **`tribonacci_recurrence_model`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.families`. Research cards: C.2C tribonacci_recurrence_model.

AG-1102 **`TruncatedPadic`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.arithmetic.domains`. Research cards: C.1G TruncatedPadic.

AG-1103 **`TruncatedPadicDomain`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.generating.domains`. Research cards: C.3A TruncatedPadicDomain.

AG-1104 **`TruncatedPowerPacket`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.singular_packets`. Research cards: C.4B TruncatedPowerPacket, C.4B TruncatedPowerTerm.

AG-1105 **`type_from_dict`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B type_from_dict.

AG-1106 **`type_to_dict`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.portable`. Research cards: C.1B type_to_dict.

AG-1107 **`UnifiedStage`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.unified`. Research cards: C.1G UnifiedStage.

AG-1108 **`UnifiedSystem`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.unified`. Research cards: C.1G UnifiedSystem.

AG-1109 **`universal_threshold`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B universal_threshold.

AG-1110 **`upsample`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.resampling`. Research cards: C.4A upsample.

AG-1111 **`validate_cupy_snapshot`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.gpu`. Research cards: C.5B validate_cupy_snapshot, C.1E validate_cupy_snapshot.

AG-1112 **`Variance`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.2C Variance.

AG-1113 **`variation_of_constants_prefix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.recurrence`. Research cards: C.2C variation_of_constants_prefix, C.1C variation_of_constants_prefix.

AG-1114 **`Vector`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `builtins`. Research cards: C.2C Vector.

AG-1115 **`VectorJumpRecoveryResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.edge_recovery`. Research cards: C.4B VectorJumpRecoveryResult.

AG-1116 **`verify_cyclotomic_coboundary`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cyclotomic`. Research cards: C.3B verify_cyclotomic_coboundary.

AG-1117 **`verify_cyclotomic_exponent_relation`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.cyclotomic`. Research cards: C.3B verify_cyclotomic_exponent_relation.

AG-1118 **`verify_finite_filtered_branch`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.nonlinear.filtered`. Research cards: C.5A verify_finite_filtered_branch, C.1E verify_finite_filtered_branch.

AG-1119 **`VisibilityTree`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.deformation.visibility`. Research cards: C.1G VisibilityTree.

AG-1120 **`walsh_hadamard_transform`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.numeric`. Research cards: C.2C walsh_hadamard_transform.

AG-1121 **`WalshHadamardOperator`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.algorithms.structured`. Research cards: C.1D WalshHadamardOperator.

AG-1122 **`warn_deprecated`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.compatibility`. Research cards: C.1A warn_deprecated.

AG-1123 **`wavelet_denoise`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B wavelet_denoise.

AG-1124 **`WaveletDenoiseResult`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.denoise`. Research cards: C.4B WaveletDenoiseResult.

AG-1125 **`weakest_exactness`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.certification`. Research cards: C.1B weakest_exactness.

AG-1126 **`weighted_bell_digit_reduction`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.bell`. Research cards: C.3B weighted_bell_digit_reduction.

AG-1127 **`weighted_factorial_power_bell_function`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.functions`. Research cards: C.3A weighted_factorial_power_bell_function.

AG-1128 **`weighted_generalized_bell_numbers`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A weighted_generalized_bell_numbers.

AG-1129 **`weighted_generalized_bell_polynomials`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.sequences`. Research cards: C.3A weighted_generalized_bell_polynomials.

AG-1130 **`WeightedTransferEdge`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.refinement.weighted`. Research cards: C.1G WeightedTransferEdge.

AG-1131 **`WeightedTransferGraph`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.refinement.weighted`. Research cards: C.1G WeightedTransferGraph.

AG-1132 **`welch_psd`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.spectral`. Research cards: C.4A welch_psd.

AG-1133 **`window_metrics`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.signals.windows`. Research cards: C.4A window_metrics.

AG-1134 **`WindowMetrics`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.signals.windows`. Research cards: C.4A WindowMetrics.

AG-1135 **`WindowName`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A WindowName.

AG-1136 **`WindowSpec`**. Strongest listed tier `[RESEARCH]`. Kinds: `data`. Owners: `typing`. Research cards: C.4A WindowSpec.

AG-1137 **`zero_borrow_count`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.generating.masks`. Research cards: C.3B zero_borrow_count.

AG-1138 **`zero_map`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.expression.model`. Research cards: C.1B zero_map.

AG-1139 **`zero_matrix`**. Strongest listed tier `[RESEARCH]`. Kinds: `function`. Owners: `komorebi_math.coordinates.exact`. Research cards: C.2A zero_matrix.

AG-1140 **`ZeroMap`**. Strongest listed tier `[RESEARCH]`. Kinds: `class`. Owners: `komorebi_math.expression.model`. Research cards: C.1B ZeroMap.

> **Reference connections.** The 1,312 research cards and four derived indexes connect public routes and implementation owners. Appendix D joins those owners and routes to the source-module ledger. These indexes record the reference baseline and do not by themselves qualify a new release.

Appendix D. Module reference ledger

Using the module ledger. Start with an API card when you need to call an operation. Use this appendix when you need to locate its implementation, understand its neighboring modules, or trace a dependency or diagnostic. The family summary narrows the search; the module card then gives the source path and links to the API names it owns.

Module-card field	How to use it
Purpose and source	Identify the module and the source revision represented by the record.
Surface and ownership	Distinguish an implementation owner from a facade or internal support module; follow the linked API card for a public contract.
Direct package dependencies	See the modules this module imports directly in the recorded analysis.
Reverse package dependents	See which package modules import this module directly.
Examples, tests, and documentation	Find files with the recorded direct references, then read them in context.

A facade is a convenient import surface that exposes objects implemented elsewhere. For instance, a stable route can lead to an implementation in a domain module. Follow the stable card when deciding which compatibility promise your program relies on; follow the implementation path when reading the source. Importability by itself does not make an internal module a supported application interface.

Dependency lists in these cards describe direct references. They are useful for tracing an import, but they are not a complete installation recipe or a measurement of runtime memory. Consult Appendix J for dependencies and Appendix K for resource guidance. Likewise, a zero in an example or test column means that the particular static join found no direct match. It does not establish that no code path ever exercises the module.

The printed cards abbreviate long file and edge lists. Section D.4 identifies the machine-readable ledger containing the complete arrays. Use Appendix O for the separate current-source test and verification inventory. Keeping these two inventories distinct prevents a reference-source count from being mistaken for a count of a later source tree.

Appendix D records every Python source module in the reference package under `src/komorebi_math`. It separates public API ownership from importability, package facades, internal support, verification, release tooling, command-line implementation, backend adapters, and extension infrastructure. A module can be importable without being covered by a stable, beta, or research compatibility promise.

$$M = (module, source, role, public, owner, domain, exports, tiers, deps, examples, tests, docs, status).$$

The inventory is derived from the reference filesystem, the three committed API manifests, runtime imports, module docstrings, declared export lists, direct import edges, and exact references found in examples, tests, and documentation. Evidence file lists are static direct-reference joins. A zero in that join does not prove that a module is behaviorally untested through another facade. Purpose descriptions summarize source docstrings. Exactness and qualification remain governed by the object contracts and recorded evidence, rather than by a module label.

D.1 Inventory, roles, and closure rules

Inventory	Count
Package source modules	300
Package initializers	30
Ordinary module files	270
Package modules owning at least one API card	202
Package modules owning at least one research card	196
Package modules with no manifest-owned card	98
Implementation-owner strings across all tiers	207
Research implementation-owner strings	201
External standard-library owner strings	5
Direct package dependency edges	1,591

Module role	Modules
public implementation owner	200
installed verification module	28
importable package facade outside API manifests	17
unmanifested implementation support	17
internal support module	10
canonical API namespace facade	9
release infrastructure module	7
backend adapter module	4
command line implementation module	3
extension infrastructure module	3
canonical API namespace facade and owner	2
Total	**300**

A module is marked as an API implementation owner only when at least one committed manifest card names it as `implementation_module`. Canonical namespace facades are recorded separately because they re-export objects whose implementations usually live elsewhere. Modules with a private path segment remain internal even when they define `__all__`. Verification and release modules are shipped operational surfaces, not compatibility tiers.

D.1.1 Family summary

Family	Modules	Initializers	API owners	Research owners
`package root`	22	1	11	7
`api`	2	1	0	0
`beta`	1	1	0	0
`backends`	4	1	0	0
`core`	10	1	9	9

Package-owned API cards	**119**	**73**	**1257**

The family table counts cards owned by package modules. The five external owner rows account for the remaining manifest cards.

Ownership source	Stable cards	Beta cards	Research cards	Total
Package source modules	119	73	1257	1449
External owner rows	12	10	55	77
All manifest cards	**131**	**83**	**1312**	**1526**

Ownership source	Stable cards	Beta cards	Research cards	Total

D.2 Package source-module cards

The 300 cards below are ordered by package family and fully qualified module name. Each card states the module role, exact source path, source size and digest, manifest ownership, declared module-level names, direct dependencies, reverse package dependents, and direct example, test, and documentation references. Full lists are retained in the JSON and CSV ledgers when a printed card abbreviates a long field.

D.2.1 Package Root: 22 modules

D.2.1.1 `komorebi_math`

Purpose and source. Executable mathematics for the Komorebi Math research program. It is the package initializer for the `package root` family. The ledger classifies it as a canonical API namespace facade. Source `src/komorebi_math/__init__.py` contains 1,072 lines and 27,312 bytes. Source SHA-256 begins `b427cf245f4876c3`.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 516 names: `__version__`, `add`, `affine_interval_change_of_variables`, `affine_mahler_kernel`, `affine_substitution`, `AffineCoordinateTransform`, `Algebra BasisResult`, `all_fubini_orders`, `AlternatingForm`, `analysis_synthesis_integration_certificate`, and 506 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (96): `komorebi_math._features`, `komorebi_math._version`, `komorebi_math.algorithms`, `komorebi_math.analytic`, `komorebi_math.arithmetic`, `komorebi_math.certificates`, and 90 more in the machine-readable ledger. Reverse package dependents (0): none. Examples (65): `automatic_holonomic.py`, `block11_semantic_profile.py`, `block15_polyphase_refinement.py`, `block16_analysis_synthesis.py`, `block19_measure_integration_worked_example.py`, and 60 more in the machine-readable ledger. Tests or test support files (126): `optional_backend_support.py`, `test_algebra_quotients.py`, `test_algorithms_compiler.py`, `test_algorithms_complexity_benchmarks.py`, `test_algorithms_discovery_gpu.py`, and 121 more in the machine-readable ledger. Documentation files with literal module or public-route references (43): `ANALYSIS_SYNTHESIS_SYSTEMS.md`, `API_COMPATIBILITY_0.11.md`, `API_COMPATIBILITY_0.12.md`, `API_COMPATIBILITY_0.13.md`, `API_COMPATIBILITY_0.14.md`, and 38 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.2 `komorebi_math.__main__`

Purpose and source. Package command entry point. It is an ordinary module in the `package root` family. The ledger classifies it as an internal support module. Source `src/komorebi_math/__main__.py` contains 4 lines and 84 bytes. Source SHA-256 begins `39a0ee4edd1039df`.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found no top-level public definitions.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.cli.main`. Reverse package dependents (0): none. Examples (8): `Test-KomorebiBlock10.ps1`, `Test-KomorebiBlock11.ps1`, `Test-KomorebiBlock12.ps1`, `Test-KomorebiBlock13.ps1`, `Test-KomorebiBlock14.ps1`, and 3 more in the machine-readable ledger. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.3 komorebi_math._features

Purpose and source. Built-in feature declarations. It is an ordinary module in the package root family. The ledger classifies it as an internal support module. Source src/komorebi_math/_features.py contains 370 lines and 15,118 bytes. Source SHA-256 begins 87e70493395fae52.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: register_builtin_features.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.registry. Reverse package dependents (1): komorebi_math. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.4 komorebi_math._number_theory

Purpose and source. Small exact number-theoretic validation helpers used across the package. It is an ordinary module in the package root family. The ledger classifies it as an internal support module. Source src/komorebi_math/_number_theory.py contains 52 lines and 1,439 bytes. Source SHA-256 begins d125f065a96f24bb.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 3 names: is_prime, require_integer, require_prime.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (33): komorebi_math.arithmetic.domains, komorebi_math.arithmetic.euler, komorebi_math.arithmetic.hurwitz, komorebi_math.arithmetic.local_modes, komorebi_math.arithmetic.mahler, komorebi_math.arithmetic.polyphase, and 27 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.5 komorebi_math._planned

Purpose and source. Shared utilities for declared but unimplemented feature modules. It is an ordinary module in the package root family. The ledger classifies it as an internal support module. Source src/komorebi_math/_planned.py contains 20 lines and 705 bytes. Source SHA-256 begins 660a23f170c6fe9d.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 2 top-level public definitions: development_status, require_implemented.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.exceptions, komorebi_math.registry. Reverse package dependents (12): komorebi_math.analytic, komorebi_math.arithmetic, komorebi_math.deformation, komorebi_math.dynamics, komorebi_math.langlands.completion, komorebi_math.langlands.finite_image, and 6 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.6 komorebi_math._version

Purpose and source. Installed package version constant. It is an ordinary module in the package root family. The ledger classifies it as an internal support module. Source src/komorebi_math/_version.py contains 1 lines and 24 bytes. Source SHA-256 begins bfdd9f8d756a3db5.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found no top-level public definitions.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (13): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.compatibility`, `komorebi_math.export.persistence`, `komorebi_math.nonlinear.streaming`, `komorebi_math.persistence_contract`, and 7 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.7 `komorebi_math.certificates`

Purpose and source. Typed certificates and result wrappers. It is an ordinary module in the `package root` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/certificates.py` contains 86 lines and 2,435 bytes. Source SHA-256 begins `a437769b196f24ba`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 4 stable, 4 beta, and 4 research. Linked cards: Certificate, ComputationResult, ConditionalResult, Exactness, Certificate, ComputationResult, ConditionalResult, Exactness, Certificate, ComputationResult, and 2 more in the machine-readable ledger. Static analysis found 4 top-level public definitions: `Certificate`, `ComputationResult`, `ConditionalResult`, `Exactness`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.exceptions`. Reverse package dependents (169): `komorebi_math`, `komorebi_math.algorithms.compiler`, `komorebi_math.algorithms.discovery`, `komorebi_math.algorithms.gpu`, `komorebi_math.algorithms.ir`, `komorebi_math.algorithms.krylov`, and 163 more in the machine-readable ledger. Examples (2): `nonlinear_jets_composition.py`, `scalable_nonlinear.py`. Tests or test support files (15): `test_analytic_appell_zeros.py`, `test_block10_execution_persistence.py`, `test_block10_sparse_autodiff.py`, `test_block11_streaming_migrations.py`, `test_block19_integration.py`, and 10 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.8 `komorebi_math.compatibility`

Purpose and source. Deterministic public-API manifests and additive compatibility checks. It is an ordinary module in the `package root` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/compatibility.py` contains 653 lines and 23,790 bytes. Source SHA-256 begins `9422447e4d0c996c`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 26 manifest cards: 6 stable, 6 beta, and 14 research. Linked cards: ApiCompatibilityReport, check_stable_api, create_stable_api_manifest, load_stable_api_manifest, PublicApiManifest, PublicApiSymbol, ApiCompatibilityReport, check_beta_api, create_beta_api_manifest, load_beta_api_manifest, and 16 more in the machine-readable ledger. Its `__all__` declaration contains 29 names: `API_STABILITY_LEVEL`, `ApiCompatibilityReport`, `BETA_API_STABILITY_LEVEL`, `BETA_PUBLIC_NAMESPACES`, `check_beta_api`, `check_public_api`, `check_stable_api`, `compare_public_api`, `create_beta_api_manifest`, `create_public_api_manifest`, and 19 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math._version`, `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (13): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.cli.main`, `komorebi_math.qualification`, `komorebi_math.release.contract`, `komorebi_math.release.documentation`, and 7 more in the machine-readable ledger. Examples (1): `block21_public_capability_tour.py`. Tests or test support files (13): `test_block10_cli.py`, `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, `test_block12_cli_api.py`, `test_block13_cli_api.py`, and 8 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.9 `komorebi_math.config`

Purpose and source. Runtime settings for backend and validation defaults. It is an ordinary module in the `package root` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/config.py` contains 60 lines and 1,643 bytes. Source SHA-256 begins `b6a5591e3d32ed49`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 4 stable, 0 beta, and 4 research. Linked cards: configure, get_settings, Settings, settings_context, configure, get_settings, Settings, settings_context. Static analysis found 4 top-level public definitions: `configure`, `get_settings`, `Settings`, `settings_context`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (8): `komorebi_math`, `komorebi_math.core.algebra`, `komorebi_math.core.packets`, `komorebi_math.core.realization`, `komorebi_math.core.seeds`, `komorebi_math.qualification`, and 2 more in the machine-readable ledger. Examples (0): none. Tests or test support files (1): `test_certificates_registry.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.10 `komorebi_math.exceptions`

Purpose and source. Package-specific exception hierarchy. It is an ordinary module in the `package root` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/exceptions.py` contains 39 lines and 1,157 bytes. Source SHA-256 begins `65aee29fea129eec`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 13 manifest cards: 7 stable, 6 beta, and 0 research. Linked cards: AssumptionError, BackendUnavailableError, DimensionError, ExactnessError, KomorebiMathError, ResourceLimitError, ValidationError, AssumptionError, BackendUnavailableError, DimensionError, and 3 more in the machine-readable ledger. Static analysis found 9 top-level public definitions: `AssumptionError`, `BackendUnavailableError`, `DimensionError`, `ExactnessError`, `FeatureNotImplementedError`, `KomorebiMathError`, `RelationError`, `ResourceLimitError`, `ValidationError`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (214): `komorebi_math._number_theory`, `komorebi_math._planned`, `komorebi_math.algorithms._validation`, `komorebi_math.algorithms.benchmarks`, `komorebi_math.algorithms.compiler`, `komorebi_math.algorithms.complexity`, and 208 more in the machine-readable ledger. Examples (2): `block19_measure_integration_worked_example.py`, `portable_nonlinear_state.py`. Tests or test support files (70): `test_algorithms_compiler.py`, `test_algorithms_complexity_benchmarks.py`, `test_algorithms_discovery_gpu.py`, `test_algorithms_krylov.py`, `test_algorithms_layout_ir.py`, and 65 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.11 `komorebi_math.golden`

Purpose and source. Deterministic behavioral fixtures for release-level semantic regression. It is an ordinary module in the `package root` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/golden.py` contains 625 lines and 23,737 bytes. Source SHA-256 begins `af7f39387bb8aa35`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 0 stable, 4 beta, and 4 research. Linked cards: BehavioralGoldenCaseResult, BehavioralGoldenReport, load_behavioral_golden_fixture, run_behavioral_golden_fixture, BehavioralGoldenCaseResult, BehavioralGoldenReport, load_behavioral_golden_fixture, run_behavioral_golden_fixture. Its `__all__` declaration contains 7 names: `BEHAVIORAL_GOLDEN_SCHEMA`, `BEHAVIORAL_GOLDEN_SCHEMA_VERSION`, `BehavioralGoldenCaseResult`, `BehavioralGoldenReport`, `DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE`, `load_behavioral_golden_fixture`, `run_behavioral_golden_fixture`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (22): `komorebi_math.certificates`, `komorebi_math.coordinates`, `komorebi_math.coordinates.basis`, `komorebi_math.coordinates.classical`, `komorebi_math.coordinates.combinatorial`, `komorebi_math.coordinates.formal`, and 16 more in the machine-readable ledger. Reverse package dependents (4): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.cli.main`, `komorebi_math.verify.streaming_beta`. Examples (1): `block11_semantic_profile.py`. Tests or test support files (1): `test_block11_golden_profiling_beta.py`. Documentation files with literal module or public-route references

(1): BEHAVIORAL_GOLDEN_AND_PROFILING.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.12 komorebi_math.persistence_contract

Purpose and source. Frozen portable-codec inventory and migration-path compatibility checks. It is an ordinary module in the package root family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/persistence_contract.py contains 333 lines and 13,146 bytes. Source SHA-256 begins f70374c8b7101775.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 8 stable, 0 beta, and 0 research. Linked cards: check_portable_codec_contract, compare_portable_codec_contract, create_portable_codec_contract, load_portable_codec_contract, PortableCodecCompatibilityReport, PortableCodecContract, PortableCodecContractEntry, save_portable_codec_contract. Its __all__ declaration contains 11 names: check_portable_codec_contract, compare_portable_codec_contract, create_portable_codec_contract, DEFAULT_PORTABLE_CODEC_CONTRACT, load_portable_codec_contract, PORTABLE_CODEC_CONTRACT_SCHEMA, PORTABLE_CODEC_CONTRACT_SCHEMA_VERSION, PortableCodecCompatibilityReport, PortableCodecContract, PortableCodecContractEntry, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math._version, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.export.persistence. Reverse package dependents (6): komorebi_math.release.contract, komorebi_math.release.upgrade, komorebi_math.stable, komorebi_math.stable_contract, komorebi_math.verify.release, komorebi_math.verify.stabilization. Examples (0): none. Tests or test support files (2): test_block16_contracts.py, test_block19_integration.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.13 komorebi_math.provenance

Purpose and source. Mathematical provenance registry for public objects. It is an ordinary module in the package root family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/provenance.py contains 78 lines and 2,216 bytes. Source SHA-256 begins 64c95e2cf499a0c9.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: ClaimStatus, describe, ProvenanceRecord. Static analysis found 6 top-level public definitions: ClaimStatus, describe, documented, ProvenanceRecord, records, register_record.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (100): komorebi_math, komorebi_math.algorithms.compiler, komorebi_math.algorithms.complexity, komorebi_math.algorithms.discovery, komorebi_math.algorithms.ir, komorebi_math.algorithms.krylov, and 94 more in the machine-readable ledger. Examples (0): none. Tests or test support files (1): test_certificates_registry.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.14 komorebi_math.qualification

Purpose and source. Release qualification and stable semantic regression for Komorebi Math. It is an ordinary module in the package root family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/qualification.py contains 431 lines and 16,046 bytes. Source SHA-256 begins bbc2a27a6c3f797f.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 10 names: gpu_diagnostics, QualificationCheck, QualificationVerificationReport, RELEASE_CANDIDATE_VERSION, RELEASE_QUALIFICATION_SCHEMA, RELEASE_QUALIFICATION_SCHEMA_VERSION, ReleaseQualificationReport, run_release_qualification, run_stable_semantic_verification, runtime_inventory.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (20): komorebi_math._version, komorebi_math.api, komorebi_math.api.v1, komorebi_math.arithmetic, komorebi_math.certificates, komorebi_math.compatibility, and 14 more in the machine-readable ledger. Reverse package dependents (2): komorebi_math.cli.main, komorebi_math.verify.gpu. Examples (0): none. Tests or test support files (1): test_

block16_release_qualification.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.15 komorebi_math.registry

Purpose and source. Feature registry for implemented and planned mathematical domains. It is an ordinary module in the package root family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/registry.py contains 72 lines and 2,058 bytes. Source SHA-256 begins e4e93781427a808f.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: feature, features, FeatureSpec, FeatureStatus. Static analysis found 6 top-level public definitions: feature, FeatureRegistry, features, FeatureSpec, FeatureStatus, register_feature.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (19): komorebi_math, komorebi_math._features, komorebi_math._planned, komorebi_math.algorithms, komorebi_math.analytic, komorebi_math.arithmetic, and 13 more in the machine-readable ledger. Examples (0): none. Tests or test support files (3): test_block13_cli_api.py, test_block14_cli_api.py, test_certificates_registry.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.16 komorebi_math.stable

Purpose and source. Curated 1.0 freeze-candidate API for Komorebi Math. It is an ordinary module in the package root family. The ledger classifies it as a canonical API namespace facade. Source src/komorebi_math/stable.py contains 298 lines and 8,473 bytes. Source SHA-256 begins 8fc11ed02b8971c9.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 131 names: __version__, AnalysisSynthesisBlocks, AnalysisSynthesisSystem, ApiCompatibilityReport, arithmetic_mixed_radix_address, arithmetic_mixed_radix_digits, arithmetic_polyphase_analyze, arithmetic_polyphase_synthesize, ArithmeticPolyphase, Arrow, and 121 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (30): komorebi_math._version, komorebi_math.arithmetic.polyphase, komorebi_math.certificates, komorebi_math.compatibility, komorebi_math.config, komorebi_math.coordinates, and 24 more in the machine-readable ledger. Reverse package dependents (7): komorebi_math.api.v1, komorebi_math.qualification, komorebi_math.release.readiness, komorebi_math.stable_semantics, komorebi_math.v1, komorebi_math.verify.release, and 1 more in the machine-readable ledger. Examples (2): block16_analysis_synthesis.py, block21_public_capability_tour.py. Tests or test support files (8): test_block15_polyphase_refinement.py, test_block15_stable_api.py, test_block16_analysis_synthesis.py, test_block16_companion_crosswalk.py, test_block16_contracts.py, and 3 more in the machine-readable ledger. Documentation files with literal module or public-route references (10): ANALYSIS_SYNTHESIS_SYSTEMS.md, API_COMPATIBILITY_0.15.md, API_INVENTORY.md, BLOCK_15_RELEASE.md, BLOCK_16_RELEASE.md, and 5 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.17 komorebi_math.stable_contract

Purpose and source. Aggregate structural, semantic, and persistence compatibility for 1.0. It is an ordinary module in the package root family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/stable_contract.py contains 87 lines and 3,104 bytes. Source SHA-256 begins 80cf6fe3febe6803.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 2 stable, 0 beta, and 0 research. Linked cards: check_stable_contract, StableContractReport. Its __all__ declaration contains 2 names: check_stable_contract, StableContractReport.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.compatibility, komorebi_math.persistence_contract, komorebi_math.stable_semantics. Reverse package dependents

(4): komorebi_math.qualification, komorebi_math.release.readiness, komorebi_math.stable, komorebi_math.verify.stabilization. Examples (0): none. Tests or test support files (1): test_block16_contracts.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.18 komorebi_math.stable_semantics

Purpose and source. Closed semantic regression fixture for the 1.0-candidate API. It is an ordinary module in the package root family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/stable_semantics.py contains 452 lines and 17,237 bytes. Source SHA-256 begins 739e76603fef9645.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 4 stable, 0 beta, and 0 research. Linked cards: load_stable_semantics_fixture, run_stable_semantics_fixture, StableSemanticCaseResult, StableSemanticReport. Its __all__ declaration contains 7 names: DEFAULT_STABLE_SEMANTICS_FIXTURE, load_stable_semantics_fixture, run_stable_semantics_fixture, STABLE_SEMANTICS_SCHEMA, STABLE_SEMANTICS_SCHEMA_VERSION, StableSemanticCaseResult, StableSemanticReport.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (16): komorebi_math.arithmetic.polyphase, komorebi_math.certificates, komorebi_math.config, komorebi_math.coordinates.analysis_synthesis, komorebi_math.coordinates.basis, komorebi_math.core.grammar, and 10 more in the machine-readable ledger. Reverse package dependents (6): komorebi_math.release.contract, komorebi_math.release.upgrade, komorebi_math.stable, komorebi_math.stable_contract, komorebi_math.verify.release, komorebi_math.verify.stabilization. Examples (0): none. Tests or test support files (2): test_block16_contracts.py, test_block18_frame_algebra.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.19 komorebi_math.support

Purpose and source. Machine-readable support policy and runtime environment inspection. It is an ordinary module in the package root family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/support.py contains 201 lines and 7,232 bytes. Source SHA-256 begins 34a2beb47434175b.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 7 names: DEFAULT_SUPPORT_MATRIX, load_support_matrix, runtime_environment, SUPPORT_MATRIX_SCHEMA, SUPPORT_MATRIX_SCHEMA_VERSION, SupportMatrix, ValidatedEnvironment.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.exceptions, komorebi_math.nonlinear.autodiff. Reverse package dependents (4): komorebi_math.qualification, komorebi_math.release.contract, komorebi_math.release.readiness, komorebi_math.verify.release. Examples (0): none. Tests or test support files (1): test_block16_contracts.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.20 komorebi_math.typing

Purpose and source. Shared type aliases used by the public API. It is an ordinary module in the package root family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/typing.py contains 16 lines and 507 bytes. Source SHA-256 begins 70a5dcaba944a26d.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found no top-level public definitions.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (0): none. Reverse package dependents (0): none. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.21 `komorebi_math.unified`

Purpose and source. The common executable language used across Komorebi Math domains. It is an ordinary module in the `package root` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/unified.py` contains 199 lines and 9,187 bytes. Source SHA-256 begins `025c94a00ccd651a`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: StageSpec, UnifiedStage, UnifiedSystem. Static analysis found 3 top-level public definitions: `StageSpec`, `UnifiedStage`, `UnifiedSystem`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (9): `komorebi_math.certificates`, `komorebi_math.core.grammar`, `komorebi_math.core.operators`, `komorebi_math.core.packets`, `komorebi_math.core.realization`, `komorebi_math.core.seeds`, and 3 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math`. Examples (1): `quickstart.py`. Tests or test support files (1): `test_unified_extensions_cli.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.1.22 `komorebi_math.v1`

Purpose and source. Convenience alias for the curated version 1 API. It is an ordinary module in the `package root` family. The ledger classifies it as a canonical API namespace facade. Source `src/komorebi_math/v1.py` contains 6 lines and 143 bytes. Source SHA-256 begins `c2d39f24ed6249f6`.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 131 names: `__version__`, `AnalysisSynthesisBlocks`, `AnalysisSynthesisSystem`, `ApiCompatibilityReport`, `arithmetic_mixed_radix_address`, `arithmetic_mixed_radix_digits`, `arithmetic_polyphase_analyze`, `arithmetic_polyphase_synthesize`, `ArithmeticPolyphase`, `Arrow`, and 121 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.stable`. Reverse package dependents (3): `komorebi_math.qualification`, `komorebi_math.release.readiness`, `komorebi_math.verify.stabilization`. Examples (0): none. Tests or test support files (5): `test_block15_polyphase_refinement.py`, `test_block15_stable_api.py`, `test_block16_analysis_synthesis.py`, `test_block16_release_contract.py`, `test_block18_frame_algebra.py`. Documentation files with literal module or public-route references (8): `API_COMPATIBILITY_0.15.md`, `API_INVENTORY.md`, `BLOCK_15_RELEASE.md`, `BLOCK_16_RELEASE.md`, `IMPLEMENTATION_ROADMAP.md`, and 3 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.2 Api: 2 modules

D.2.2.1 `komorebi_math.api`

Purpose and source. Versioned public API namespaces. It is the package initializer for the `api` family. The ledger classifies it as a canonical API namespace facade. Source `src/komorebi_math/api/__init__.py` contains 5 lines and 75 bytes. Source SHA-256 begins `844fd5e337598266`.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 1 name: `v1`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.api.v1`. Reverse package dependents (3): `komorebi_math.qualification`, `komorebi_math.release.readiness`, `komorebi_math.verify.stabilization`. Examples (0): none. Tests or test support files (5): `test_block15_polyphase_refinement.py`, `test_block15_stable_api.py`, `test_block16_analysis_synthesis.py`, `test_block16_release_contract.py`, `test_block18_frame_algebra.py`. Documentation files with literal module or public-route references (9): `API_COMPATIBILITY_0.15.md`, `API_INVENTORY.md`, `BLOCK_15_RELEASE.md`, `BLOCK_16_RELEASE.md`, `IMPLEMENTATION_ROADMAP.md`, and 4 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.2.2 komorebi_math.api.v1

Purpose and source. Version 1 compatibility alias for komorebi_math.stable. It is an ordinary module in the api family. The ledger classifies it as a canonical API namespace facade. Source src/komorebi_math/api/v1.py contains 6 lines and 159 bytes. Source SHA-256 begins 053a732923c0c611.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 131 names: __version__, AnalysisSynthesisBlocks, AnalysisSynthesisSystem, ApiCompatibilityReport, arithmetic_mixed_radix_address, arithmetic_mixed_radix_digits, arithmetic_polyphase_analyze, arithmetic_polyphase_synthesize, ArithmeticPolyphase, Arrow, and 121 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.stable. Reverse package dependents (4): komorebi_math.api, komorebi_math.qualification, komorebi_math.release.readiness, komorebi_math.verify.stabilization. Examples (0): none. Tests or test support files (5): test_block15_polyphase_refinement.py, test_block15_stable_api.py, test_block16_analysis_synthesis.py, test_block16_release_contract.py, test_block18_frame_algebra.py. Documentation files with literal module or public-route references (8): API_COMPATIBILITY_0.15.md, API_INVENTORY.md, BLOCK_15_RELEASE.md, BLOCK_16_RELEASE.md, IMPLEMENTATION_ROADMAP.md, and 3 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.3 Beta: 1 module

D.2.3.1 komorebi_math.beta

Purpose and source. Curated beta-compatibility surface for finite packet execution and persistence. It is the package initializer for the beta family. The ledger classifies it as a canonical API namespace facade. Source src/komorebi_math/beta/__init__.py contains 197 lines and 5,520 bytes. Source SHA-256 begins b56d0c7448fdcdfb.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 83 names: __version__, ApiCompatibilityReport, AssumptionError, BackendUnavailableError, BEHAVIORAL_GOLDEN_SCHEMA, BEHAVIORAL_GOLDEN_SCHEMA_VERSION, BehavioralGoldenCaseResult, BehavioralGoldenReport, BETA_API_STABILITY_LEVEL, CallableDerivativeProvider, and 73 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (14): komorebi_math._version, komorebi_math.certificates, komorebi_math.compatibility, komorebi_math.core, komorebi_math.exceptions, komorebi_math.export.persistence, and 8 more in the machine-readable ledger. Reverse package dependents (0): none. Examples (0): none. Tests or test support files (3): test_block11_golden_profiling_beta.py, test_block12_cli_api.py, test_block19_integration.py. Documentation files with literal module or public-route references (10): API_COMPATIBILITY_0.11.md, API_COMPATIBILITY_0.12.md, API_COMPATIBILITY_0.13.md, API_COMPATIBILITY_0.14.md, API_INVENTORY.md, and 5 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.4 Backends: 4 modules

D.2.4.1 `komorebi_math.backends`

Purpose and source. Backend discovery and selection. It is the package initializer for the `backends` family. The ledger classifies it as a backend adapter module. Source `src/komorebi_math/backends/__init__.py` contains 63 lines and 1,857 bytes. Source SHA-256 begins `b5a016ff2b71593a`.

Surface and ownership. API classification: backend implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 6 names: `available_backends`, `backend_name`, `get_backend`, `LinearAlgebraBackend`, `NumpyBackend`, `register_backend`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math.backends.base`, `komorebi_math.backends.numpy`, `komorebi_math.backends.sympy`, `komorebi_math.exceptions`. Reverse package dependents (11): `komorebi_math.cli.main`, `komorebi_math.core.algebra`, `komorebi_math.core.morphisms`, `komorebi_math.core.packets`, `komorebi_math.core.realization`, `komorebi_math.core.seeds`, and 5 more in the machine-readable ledger. Examples (0): none. Tests or test support files (2): `test_backends.py`, `test_morphisms.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.4.2 `komorebi_math.backends.base`

Purpose and source. Linear algebra backend interface used by the finite-dimensional core. It is an ordinary module in the `backends` family. The ledger classifies it as a backend adapter module. Source `src/komorebi_math/backends/base.py` contains 68 lines and 1,696 bytes. Source SHA-256 begins `08139171a8fa5660`.

Surface and ownership. API classification: backend implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: `LinearAlgebraBackend`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (3): `komorebi_math.backends`, `komorebi_math.backends.numpy`, `komorebi_math.backends.sympy`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.4.3 `komorebi_math.backends.numpy`

Purpose and source. NumPy backend. It is an ordinary module in the `backends` family. The ledger classifies it as a backend adapter module. Source `src/komorebi_math/backends/numpy.py` contains 96 lines and 3,410 bytes. Source SHA-256 begins `ff1acb35928ecc8b`.

Surface and ownership. API classification: backend implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: `NumpyBackend`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): `komorebi_math.backends.base`, `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.backends`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.4.4 `komorebi_math.backends.sympy`

Purpose and source. Optional exact SymPy backend. It is an ordinary module in the `backends` family. The ledger classifies it as a backend adapter module. Source `src/komorebi_math/backends/sympy.py` contains 104 lines and 3,003 bytes. Source SHA-256 begins `8f5082c8e05db32e`.

Surface and ownership. API classification: backend implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: `SympyBackend`.

Dependencies and evidence. Direct dependency profile: optional `exact` extra. Direct package dependencies (2): `komorebi_math.backends.base`, `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.backends`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5 Core: 10 modules

D.2.5.1 `komorebi_math.core`

Purpose and source. Finite-dimensional executable foundation. It is the package initializer for the `core` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/core/__init__.py` contains 53 lines and 1,545 bytes. Source SHA-256 begins `cc9b9d613fed58b7`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 29 names: `AlgebraBasisResult`, `Arrow`, `block_from_paths`, `cyclic_span`, `FreePresentation`, `independent_direct_sum_seed_rank`, `matrix_units`, `OperatorAlgebra`, `OperatorGrammar`, `OperatorMorphism`, and 19 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (9): `komorebi_math.core.algebra`, `komorebi_math.core.grammar`, `komorebi_math.core.graphs`, `komorebi_math.core.morphisms`, `komorebi_math.core.operators`, `komorebi_math.core.packets`, and 3 more in the machine-readable ledger. Reverse package dependents (17): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.dynamics.semigroups`, `komorebi_math.golden`, `komorebi_math.qualification`, `komorebi_math.quantum.channels`, and 11 more in the machine-readable ledger. Examples (0): none. Tests or test support files (2): `test_quantum_symmetry_circuits.py`, `test_unified_extensions_cli.py`. Documentation files with literal module or public-route references (1): `API_INVENTORY.md`. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.2 `komorebi_math.core.algebra`

Purpose and source. Finite matrix algebras generated by operator families. It is an ordinary module in the `core` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/core/algebra.py` contains 180 lines and 7,007 bytes. Source SHA-256 begins `e62691c9a68bd448`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: AlgebraBasisResult, matrix_units, OperatorAlgebra. Static analysis found 3 top-level public definitions: `AlgebraBasisResult`, `matrix_units`, `OperatorAlgebra`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (9): `komorebi_math.backends`, `komorebi_math.certificates`, `komorebi_math.config`, `komorebi_math.core.graphs`, `komorebi_math.core.operators`, `komorebi_math.core.packets`, and 3 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.core`. Examples (1): `exact_backend.py`. Tests or test support files (1): `test_algebra_quotients.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.3 `komorebi_math.core.grammar`

Purpose and source. Typed operator grammars and formal path relations. It is an ordinary module in the `core` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/core/grammar.py` contains 231 lines and 8,368 bytes. Source SHA-256 begins `003a8bb22f6dfeac`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 4 stable, 0 beta, and 4 research. Linked cards: Arrow, OperatorGrammar, OperatorRelation, OperatorWord, Arrow, OperatorGrammar, OperatorRelation, OperatorWord. Static analysis found 4 top-level public definitions: `Arrow`, `OperatorGrammar`, `OperatorRelation`, `OperatorWord`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (4): `komorebi_math.core`, `komorebi_math.core.realization`, `komorebi_math.stable_semantic`

s, komorebi_math.unified. Examples (1): typed_grammar.py. Tests or test support files (3): test_block16_analysis_synthesis.py, test_grammar_realization.py, test_unified_extensions_cli.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.4 komorebi_math.core.graphs

Purpose and source. Transfer graphs, strongly connected components, and support preorders. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/graphs.py contains 282 lines and 11,961 bytes. Source SHA-256 begins b565ad292c4dc647.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 1 stable, 0 beta, and 2 research. Linked cards: TransferGraph, SupportPreorder, TransferGraph. Static analysis found 2 top-level public definitions: SupportPreorder, TransferGraph.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math.core, komorebi_math.core.algebra, komorebi_math.core.transfer. Examples (0): none. Tests or test support files (1): test_graphs.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.5 komorebi_math.core.morphisms

Purpose and source. Intertwining and packet-compatible morphisms. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/morphisms.py contains 181 lines and 8,067 bytes. Source SHA-256 begins 40280cd87fd19f9d.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: OperatorMorphism, PacketMorphism, SeedMorphism. Static analysis found 3 top-level public definitions: OperatorMorphism, PacketMorphism, SeedMorphism.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): komorebi_math.backends, komorebi_math.certificates, komorebi_math.core.packets, komorebi_math.core.seeds, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.core. Examples (0): none. Tests or test support files (1): test_morphisms.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.6 komorebi_math.core.operators

Purpose and source. Packet-resolved linear operators. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/operators.py contains 192 lines and 8,652 bytes. Source SHA-256 begins 5d9a3794e8fc56f6.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 1 stable, 0 beta, and 1 research. Linked cards: PacketOperator, PacketOperator. Static analysis found 1 top-level public definition: PacketOperator.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.core.packets, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (5): komorebi_math.core, komorebi_math.core.algebra, komorebi_math.core.transfer, komorebi_math.refinement.towers, komorebi_math.unified. Examples (1): quickstart.py. Tests or test support files (1): test_operators_transfer.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.7 komorebi_math.core.packets

Purpose and source. Exact finite packet systems and packet coordinates. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/packets.py contains 355 lines and 16,054 bytes. Source SHA-256 begins 02427ff27728818c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 2 stable, 1 beta, and 2 research. Linked cards: PacketCoordinates, PacketSystem, PacketSystem, PacketCoordinates, PacketSystem. Static analysis found 2 top-level public definitions: PacketCoordinates, PacketSystem.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.backends, komorebi_math.certificates, komorebi_math.config, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (13): komorebi_math.core, komorebi_math.core.algebra, komorebi_math.core.morphisms, komorebi_math.core.operators, komorebi_math.nonlinear.composition, komorebi_math.nonlinear.coordinates, and 7 more in the machine-readable ledger. Examples (9): block11_semantic_profile.py, exact_backend.py, nonlinear_jets_composition.py, portable_nonlinear_state.py, quickstart.py, and 4 more in the machine-readable ledger. Tests or test support files (19): test_algebra_quotients.py, test_block10_execution_persistence.py, test_block11_cli.py, test_block11_golden_profiling_beta.py, test_block11_streaming_migrations.py, and 14 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.8 komorebi_math.core.realization

Purpose and source. Matrix realizations of typed operator grammars. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/realization.py contains 147 lines and 6,210 bytes. Source SHA-256 begins 9992284c22390fbc.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 2 stable, 0 beta, and 1 research. Linked cards: OperatorRealization, RelationResidual, OperatorRealization. Static analysis found 2 top-level public definitions: OperatorRealization, RelationResidual.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): komorebi_math.backends, komorebi_math.certificates, komorebi_math.config, komorebi_math.core.grammar, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math.core, komorebi_math.stable_semantics, komorebi_math.unified. Examples (1): typed_grammar.py. Tests or test support files (2): test_grammar_realization.py, test_unified_extensions_cli.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.9 komorebi_math.core.seeds

Purpose and source. Finite-dimensional seed systems and generator calculations. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/seeds.py contains 385 lines and 15,228 bytes. Source SHA-256 begins 1962a589cce8d354.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 1 stable, 0 beta, and 7 research. Linked cards: SeedSystem, cyclic_span, independent_direct_sum_seed_rank, SeedSystem, semisimple_seed_rank, shared_direct_sum_seed_bounds, single_operator_seed_rank, tensor_seed_rank_upper_bound. Static analysis found 9 top-level public definitions: cyclic_span, FreePresentation, independent_direct_sum_seed_rank, SeedSystem, semisimple_seed_rank, shared_direct_sum_seed_bounds, single_operator_seed_rank, StandardSeedSearchResult, tensor_seed_rank_upper_bound.

Dependencies and evidence. Direct dependency profile: optional exact extra. Direct package dependencies (5): komorebi_math.backends, komorebi_math.certificates, komorebi_math.config, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (4): komorebi_math.core, komorebi_math.core.algebra, komorebi_math.core.morphisms, komorebi_math.unified. Examples (2): exact_backend.py, quickstart.py. Tests or test support files (4): test_algebra_quotients.py, test_morphisms.py, test_seeds.py, test_unified_extensions_cli.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.5.10 komorebi_math.core.transfer

Purpose and source. Path expansions for packet transfer blocks. It is an ordinary module in the core family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/core/transfer.py contains 86 lines and 3,075 bytes. Source SHA-256 begins 87bf51f7a29f7918.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 3 stable, 0 beta, and 2 research. Linked cards: block_from_paths, path_contributions, TransferPath, block_from_paths, path_contributions. Static analysis found 3 top-level public definitions: block_from_paths, path_contributions, TransferPath.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.core.graphs, komorebi_math.core.operators, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.core. Examples (0): none. Tests or test support files (1): test_operators_transfer.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6 Algorithms: 15 modules

D.2.6.1 komorebi_math.algorithms

Purpose and source. Structured operators, packet compilation, precision planning, and scheduling. It is the package initializer for the algorithms family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/algorithms/__init__.py contains 240 lines and 5,734 bytes. Source SHA-256 begins 914568810861185f.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 97 names: accumulated_recompression_bound, Address, amortization_threshold, arithmetic_intensity, as_structured_operator, assign_discrete_precisions, batched_launch_count, BDLRDiscoveryResult, benchmark_callable, BenchmarkComparison, and 87 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (14): komorebi_math.algorithms.benchmarks, komorebi_math.algorithms.compiler, komorebi_math.algorithms.complexity, komorebi_math.algorithms.discovery, komorebi_math.algorithms.gpu, komorebi_math.algorithms.ir, and 8 more in the machine-readable ledger. Reverse package dependents (3): komorebi_math, komorebi_math.release._gpu_worker, komorebi_math.verify.algorithms. Examples (5): low_rank_recompression.py, packet_compiler.py, packet_ir.py, precision_schedule.py, structured_krylov.py. Tests or test support files (10): test_algorithms_compiler.py, test_algorithms_complexity_benchmarks.py, test_algorithms_discovery_gpu.py, test_algorithms_krylov.py, test_algorithms_layout_ir.py, and 5 more in the machine-readable ledger. Documentation files with literal module or public-route references (2): API_INVENTORY.md, PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.2 komorebi_math.algorithms._validation

Purpose and source. Internal validation helpers for structured algorithm APIs. It is an ordinary module in the algorithms family. The ledger classifies it as an internal support module. Source src/komorebi_math/algorithms/_validation.py contains 59 lines and 1,768 bytes. Source SHA-256 begins 71adc32e6fdfcbbc.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 0 names: none.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (10): komorebi_math.algorithms.benchmarks, komorebi_math.algorithms.compiler, komorebi_math.algorithms.complexity, komorebi_math.algorithms.ir, komorebi_math.algorithms.krylov, komorebi_math.algorithms.low_rank, and 4 more in the machine-readable ledger. Examples (0):

none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.3 `komorebi_math.algorithms.benchmarks`

Purpose and source. Matched benchmark contracts and lightweight timing helpers. It is an ordinary module in the `algorithms` family. The ledger classifies it as unmanifested implementation support. Source `src/komorebi_math/algorithms/benchmarks.py` contains 147 lines and 4,524 bytes. Source SHA-256 begins `9f1bbd4dd9644ff5`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 6 names: `benchmark_callable`, `BenchmarkComparison`, `BenchmarkContract`, `BenchmarkResult`, `compare_benchmarks`, `TimingScope`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math.algorithms._validation`, `komorebi_math.exceptions`. Reverse package dependents (2): `komorebi_math.algorithms`, `komorebi_math.nonlinear.execution`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.4 `komorebi_math.algorithms.compiler`

Purpose and source. Exact finite compilers for additive packet representation trees. It is an ordinary module in the `algorithms` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/algorithms/compiler.py` contains 413 lines and 15,314 bytes. Source SHA-256 begins `2bf95f61c84f3fd3`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: compile_tree_budget, compile_tree_lagrangian, TreeNode. Its `__all__` declaration contains 9 names: `combine_tree_objectives`, `compile_tree_budget`, `compile_tree_lagrangian`, `decision_margins`, `DecisionMargin`, `pareto_frontier`, `replace_tree_nodes`, `TreeNode`, `TreePlan`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.algorithms._validation`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.algorithms`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.5 `komorebi_math.algorithms.complexity`

Purpose and source. Declared arithmetic, storage, data movement, and roofline cost models. It is an ordinary module in the `algorithms` family. The ledger classifies it as unmanifested implementation support. Source `src/komorebi_math/algorithms/complexity.py` contains 229 lines and 7,965 bytes. Source SHA-256 begins `2728e130cc780dd3`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 11 names: `Address`, `arithmetic_intensity`, `block_diagonal_low_rank_flops`, `block_diagonal_low_rank_storage_entries`, `CostEstimate`, `dense_apply_flops`, `packet_apply_flops`, `packet_cost_estimate`, `packet_dense_storage_entries`, `packet_streaming_bytes`, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math.algorithms._validation`, `komorebi_math.algorithms.layout`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.algorithms`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.6 komorebi_math.algorithms.discovery

Purpose and source. Restricted discovery of packet support and block-diagonal plus low-rank structure. It is an ordinary module in the algorithms family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/algorithms/discovery.py contains 171 lines and 6,929 bytes. Source SHA-256 begins 2d80ca238d92a8b5.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: discover_block_diagonal_low_rank, discover_packet_support. Its __all__ declaration contains 4 names: BDLRDiscoveryResult, discover_block_diagonal_low_rank, discover_packet_support, SupportDiscoveryResult.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (7): komorebi_math.algorithms.ir, komorebi_math.algorithms.layout, komorebi_math.algorithms.low_rank, komorebi_math.algorithms.structured, komorebi_math.certificates, komorebi_math.exceptions, and 1 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.algorithms. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.7 komorebi_math.algorithms.gpu

Purpose and source. Optional device executors for packet intermediate representations. It is an ordinary module in the algorithms family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/algorithms/gpu.py contains 134 lines and 4,498 bytes. Source SHA-256 begins 83aa2b3d85369e02.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 5 names: cupy_available, CupyPacketExecutor, DeviceExecutionResult, NumpyPacketExecutor, packet_executor.

Dependencies and evidence. Direct dependency profile: optional CuPy accelerator outside the declared project extras. Direct package dependencies (3): komorebi_math.algorithms.ir, komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.algorithms. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.8 komorebi_math.algorithms.ir

Purpose and source. Packet operator intermediate representation. It is an ordinary module in the algorithms family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/algorithms/ir.py contains 276 lines and 11,889 bytes. Source SHA-256 begins 437053d4666cfb7f.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: PacketIR. Its __all__ declaration contains 2 names: Address, PacketIR.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): komorebi_math.algorithms._validation, komorebi_math.algorithms.layout, komorebi_math.algorithms.structured, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math.algorithms, komorebi_math.algorithms.discovery, komorebi_math.algorithms.gpu. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.9 komorebi_math.algorithms.krylov

Purpose and source. Krylov methods and packet block preconditioning. It is an ordinary module in the algorithms family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/algorithms/krylov.py contains 517 lines and 19,903 bytes. Source SHA-256 begins d6c5ae7cdd4ac9be.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: conjugate_gradient. Its __all__ declaration contains 11 names: block_jacobi_certificate, block_jacobi_preconditioner, BlockJacobiCertificate, conjugate_gradient, ConjugateGradientResult, krylov_basis, KrylovBasisResult, lanczos_tridiagonal, LanczosResult, power_perturbation_bound, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): `komorebi_math.algorithms._validation`, `komorebi_math.algorithms.layout`, `komorebi_math.algorithms.structured`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.algorithms`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.10 `komorebi_math.algorithms.layout`

Purpose and source. Packet layouts for structured numerical operators. It is an ordinary module in the `algorithms` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/algorithms/layout.py` contains 195 lines and 8,058 bytes. Source SHA-256 begins `455a8d3718c57d06`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: PacketLayout. Its `__all__` declaration contains 1 name: `PacketLayout`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (6): `komorebi_math.algorithms`, `komorebi_math.algorithms.complexity`, `komorebi_math.algorithms.discovery`, `komorebi_math.algorithms.ir`, `komorebi_math.algorithms.krylov`, `komorebi_math.algorithms.structured`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.11 `komorebi_math.algorithms.low_rank`

Purpose and source. Low-rank algebra, Woodbury solves, and certified recompression. It is an ordinary module in the `algorithms` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/algorithms/low_rank.py` contains 409 lines and 15,582 bytes. Source SHA-256 begins `63f9c6af6c821014`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: BlockDiagonalLowRankOperator, LowRankOperator, recompress_factors. Its `__all__` declaration contains 7 names: `accumulated_recompression_bound`, `BlockDiagonalLowRankOperator`, `LowRankOperator`, `product_chain_error_bound`, `recompress_core`, `recompress_factors`, `RecompressionResult`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): `komorebi_math.algorithms._validation`, `komorebi_math.algorithms.structured`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (2): `komorebi_math.algorithms`, `komorebi_math.algorithms.discovery`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.12 `komorebi_math.algorithms.precision`

Purpose and source. Packetwise error certificates and precision allocation. It is an ordinary module in the `algorithms` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/algorithms/precision.py` contains 291 lines and 10,775 bytes. Source SHA-256 begins `424ffa52c460863e`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: assign_discrete_precisions, DTypeChoice. Its `__all__` declaration contains 10 names: `assign_discrete_precisions`, `clipped_precision_allocation`, `DTypeChoice`, `optimal_precision_tolerances`, `packet_error_bound`, `precision_certificate`, `PrecisionAssignment`, `quantization_error`, `quantize_array`, `quantize_by_packet`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.algorithms._validation`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.algorithms`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.13 `komorebi_math.algorithms.scheduling`

Purpose and source. Finite task graph scheduling and amortization models. It is an ordinary module in the `algorithms` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/algorithms/scheduling.py` contains 243 lines and 8,289 bytes. Source SHA-256 begins `4e82dc70675b6a01`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: schedule_unlimited, Task. Its `__all__` declaration contains 10 names: `amortization_threshold`, `batched_launch_count`, `break_even_analysis`, `BreakEvenResult`, `schedule_unlimited`, `ScheduledTask`, `shape_classes`, `Task`, `TaskSchedule`, `verify_schedule`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math.algorithms._validation`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.algorithms`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.14 `komorebi_math.algorithms.structured`

Purpose and source. Structured finite linear operators used by the packet compiler. It is an ordinary module in the `algorithms` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/algorithms/structured.py` contains 556 lines and 19,395 bytes. Source SHA-256 begins `a6a8edebd8429fed`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: BlockDiagonalOperator, CirculantOperator, DenseOperator, Walsh-HadamardOperator. Its `__all__` declaration contains 10 names: `as_structured_operator`, `BlockDiagonalOperator`, `CirculantOperator`, `DenseOperator`, `DiagonalOperator`, `IdentityOperator`, `KroneckerOperator`, `StructuredOperator`, `ToeplitzOperator`, `WalshHadamardOperator`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.algorithms._validation`, `komorebi_math.algorithms.layout`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (5): `komorebi_math.algorithms`, `komorebi_math.algorithms.discovery`, `komorebi_math.algorithms.ir`, `komorebi_math.algorithms.krylov`, `komorebi_math.algorithms.low_rank`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.6.15 `komorebi_math.algorithms.support`

Purpose and source. Structural support algebra for packet operators. It is an ordinary module in the `algorithms` family. The ledger classifies it as unmanifested implementation support. Source `src/komorebi_math/algorithms/support.py` contains 327 lines and 12,315 bytes. Source SHA-256 begins `349fe33f7f780527`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 10 names: `Address`, `inverse_support_if_acyclic`, `longest_path_vertices`, `schur_fill_support`, `support_polynomial`, `support_power`, `support_product`, `SupportGraph`, `topological_levels`, `transitive_closure`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math.algorithms._validation`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.algorithms`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7 Arithmetic: 10 modules

D.2.7.1 `komorebi_math.arithmetic`

Purpose and source. Exact local arithmetic packets, Euler coordinates, Mahler transfer, and recurrences. It is the package initializer for the `arithmetic` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/arithmetic/__init__.py` contains 189 lines and 4,614 bytes. Source SHA-256 begins `d2e6e0a6edba21d0`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 78 names: `affine_kernel_composition_certificate`, `affine_kernel_matrix`, `affine_mahler_kernel`, `ArithmeticPolyphase`, `bernoulli_numbers`, `binomial_valuation`, `binomial_valuation_from_digits`, `carmichael_exponent_prime_power`, `certify_difference_congruence`, `compressed_hurwitz_inverse`, and 68 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (11): `komorebi_math._planned`, `komorebi_math.arithmetic.domains`, `komorebi_math.arithmetic.euler`, `komorebi_math.arithmetic.hurwitz`, `komorebi_math.arithmetic.local_modes`, `komorebi_math.arithmetic.mahler`, and 5 more in the machine-readable ledger. Reverse package dependents (5): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.qualification`, `komorebi_math.verify.arithmetic`, `komorebi_math.verify.stabilization`. Examples (3): `local_euler_coordinates.py`, `recurrence_packets.py`, `standard_window_mahler.py`. Tests or test support files (8): `test_arithmetic_domains_valuation.py`, `test_arithmetic_euler.py`, `test_arithmetic_hurwitz_windows.py`, `test_arithmetic_mahler_polyphase.py`, `test_arithmetic_recurrence.py`, and 3 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.2 `komorebi_math.arithmetic.domains`

Purpose and source. Finite modular and truncated local arithmetic domains. It is an ordinary module in the `arithmetic` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/arithmetic/domains.py` contains 159 lines and 5,117 bytes. Source SHA-256 begins `47d71569e4ead7e0`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: TruncatedPadic. Its `__all__` declaration contains 3 names: `ModularRing`, `PrimeField`, `TruncatedPadic`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math._number_theory`, `komorebi_math.exceptions`. Reverse package dependents (2): `komorebi_math.arithmetic`, `komorebi_math.arithmetic.hurwitz`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.3 `komorebi_math.arithmetic.euler`

Purpose and source. Odd and dyadic Euler coordinate systems with exact local certificates. It is an ordinary module in the `arithmetic` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/arithmetic/euler.py` contains 354 lines and 13,261 bytes. Source SHA-256 begins `0e0ae8608e6fa652`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: EulerLocalCoordinates, signed_euler_number. Its `__all__` declaration contains 14 names: `bernoulli_numbers`, `dyadic_beta`, `dyadic_kernel`, `dyadic_kernel_valuation`, `dyadic_row_weight`, `dyadic_source`, `euler_zigzag_number`, `euler_zigzag_numbers`, `EulerLocalCoordinates`, `EulerTruncation`, and 4 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math._number_theory`, `komorebi_math.arithmetic.valuation`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (2): `komorebi_math.arithmetic`, `komorebi_math.sequences.catalog`. Examples (1): `export_reports.py`. Tests

or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.4 `komorebi_math.arithmetic.hurwitz`

Purpose and source. Hurwitz series, exponential modes, and finite field subgroup inversion. It is an ordinary module in the `arithmetic` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/arithmetic/hurwitz.py` contains 263 lines and 9,646 bytes. Source SHA-256 begins `1d1c43b85d0e39f0`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: HurwitzSeries. Its `__all__` declaration contains 7 names: `compressed_hurwitz_inverse`, `compressed_period`, `hurwitz_inverse`, `hurwitz_product`, `HurwitzSeries`, `subgroup_roots`, `subgroup_selector`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math._number_theory`, `komorebi_math.arithmetic.domains`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (2): `komorebi_math.arithmetic`, `komorebi_math.arithmetic.standard_windows`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.5 `komorebi_math.arithmetic.local_modes`

Purpose and source. Carmichael jumps, scalar local modes, and finite simultaneous congruences. It is an ordinary module in the `arithmetic` family. The ledger classifies it as unmanifested implementation support. Source `src/komorebi_math/arithmetic/local_modes.py` contains 151 lines and 5,269 bytes. Source SHA-256 begins `db9e8b16776da56c`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 6 names: `certify_difference_congruence`, `DifferenceCongruence`, `finite_difference_value`, `local_unit_jump`, `simultaneous_unit_difference`, `unit_mode_for_precision`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math._number_theory`, `komorebi_math.arithmetic.mahler`, `komorebi_math.arithmetic.valuation`, `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.arithmetic`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.6 `komorebi_math.arithmetic.mahler`

Purpose and source. Finite Mahler coordinates, affine reindexing, and local unit modes. It is an ordinary module in the `arithmetic` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/arithmetic/mahler.py` contains 427 lines and 16,377 bytes. Source SHA-256 begins `3f70a036ab857b89`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: affine_mahler_kernel, MahlerSeries. Its `__all__` declaration contains 12 names: `affine_kernel_composition_certificate`, `affine_kernel_matrix`, `affine_mahler_kernel`, `difference_table`, `evaluate_matrix_mahler`, `generalized_binomial`, `mahler_coefficients`, `MahlerSeries`, `matrix_mahler_coefficients`, `prime_power_kernel_certificate`, and 2 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): `komorebi_math._number_theory`, `komorebi_math.arithmetic.valuation`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (3): `komorebi_math.arithmetic`, `komorebi_math.arithmetic.local_modes`, `komorebi_math.arithmetic.polyphase`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.7 komorebi_math.arithmetic.polyphase

Purpose and source. Exact discrete and Mahler polyphase refinement for arithmetic sequences. It is an ordinary module in the arithmetic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/arithmetic/polyphase.py contains 135 lines and 5,407 bytes. Source SHA-256 begins a03e0b8499db987c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 6 stable, 0 beta, and 0 research. Linked cards: arithmetic_mixed_radix_address, arithmetic_mixed_radix_digits, arithmetic_polyphase_analyze, arithmetic_polyphase_synthesize, ArithmeticPolyphase, mahler_polyphase. Its __all__ declaration contains 6 names: ArithmeticPolyphase, mahler_polyphase, mixed_radix_address, mixed_radix_digits, polyphase_analyze, polyphase_synthesize.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.arithmetic.mahler, komorebi_math.exceptions, komorebi_math.refinement.polyphase. Reverse package dependents (5): komorebi_math.arithmetic, komorebi_math.refinement.polyphase, komorebi_math.refinement.portable, komorebi_math.stable, komorebi_math.stable_semantics. Examples (0): none. Tests or test support files (1): test_block15_polyphase_refinement.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.8 komorebi_math.arithmetic.recurrence

Purpose and source. Exact linear recurrences, residue packets, and modular orbit diagnostics. It is an ordinary module in the arithmetic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/arithmetic/recurrence.py contains 444 lines and 17,704 bytes. Source SHA-256 begins 3374acced7d63e28.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: fibonacci_recurrence, LinearRecurrence. Its __all__ declaration contains 10 names: determinant_integer, fibonacci_recurrence, LinearRecurrence, lucas_recurrence, matrix_power_exact, matrix_power_mod, OrbitPeriod, RecurrencePacket, second_order_jump, second_order_trace.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (4): komorebi_math.arithmetic, komorebi_math.coordinates.recurrence, komorebi_math.sequences.catalog, komorebi_math.sequences.compiler. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.9 komorebi_math.arithmetic.standard_windows

Purpose and source. Finite-field standard windows and congruential inverse coordinates. It is an ordinary module in the arithmetic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/arithmetic/standard_windows.py contains 223 lines and 8,478 bytes. Source SHA-256 begins a255d07bb27261ab.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: StandardWindow. Its __all__ declaration contains 6 names: PeriodicGeneratingFunction, rational_mod, standard_window_inverse, standard_window_period, StandardWindow, subgroup_standard_window_inverse.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): komorebi_math._number_theory, komorebi_math.analytic, komorebi_math.arithmetic.hurwitz, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.arithmetic. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.7.10 komorebi_math.arithmetic.valuation

Purpose and source. Exact valuations, digit sums, and local precision helpers. It is an ordinary module in the arithmetic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/arithmetic/valuation.py contains 201 lines and 6,362 bytes. Source SHA-256 begins b5b73ce2d861abfd.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: padic_valuation. Its __all__ declaration contains 11 names: binomial_valuation, binomial_valuation_from_digits, carmichael_exponent_prime_power, digit_sum, exact_binomial, factorial_valuation, falling_factorial, padic_valuation, unit_difference_valuation, unit_difference_value, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math._number_theory, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (4): komorebi_math.arithmetic, komorebi_math.arithmetic.euler, komorebi_math.arithmetic.local_modes, komorebi_math.arithmetic.mahler. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8 Sequences: 7 modules

D.2.8.1 komorebi_math.sequences

Purpose and source. Lazy exact sequences, automatic models, holonomic recurrences, and compilation. It is the package initializer for the sequences family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/sequences/__init__.py contains 92 lines and 2,241 bytes. Source SHA-256 begins ce0573d804d3d36a.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 36 names: apery_recurrence, apery_sequence, AutomaticSequence, base_digits, bell_sequence, bernoulli_sequence, binomial_transform, binomial_transform_values, catalan_sequence, cauchy_product, and 26 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (8): komorebi_math._planned, komorebi_math.registry, komorebi_math.sequences.automatic, komorebi_math.sequences.base, komorebi_math.sequences.catalog, komorebi_math.sequences.compiler, and 2 more in the machine-readable ledger. Reverse package dependents (3): komorebi_math, komorebi_math.cli.main, komorebi_math.verify.sequences. Examples (3): automatic_holonomic.py, export_reports.py, sequence_compiler.py. Tests or test support files (2): test_sequences_execution.py, test_sequences_models.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8.2 komorebi_math.sequences.automatic

Purpose and source. Finite automata with output for exact automatic sequence execution. It is an ordinary module in the sequences family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/sequences/automatic.py contains 181 lines and 6,938 bytes. Source SHA-256 begins 00eb49222a7e5cde.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: AutomaticSequence. Its __all__ declaration contains 3 names: AutomaticSequence, base_digits, thue_morse_automaton.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.sequences.base. Reverse package dependents (3): komorebi_math.sequences, komorebi_math.sequences.catalog, komorebi_math.sequences.compiler. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8.3 komorebi_math.sequences.base

Purpose and source. Lazy exact sequence objects and common sequence views. It is an ordinary module in the sequences family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/sequences/base.py contains 126 lines and 4,965 bytes. Source SHA-256 begins 7fbc0c79c09ed5d7.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: Sequence. Its __all__ declaration contains 1 name: Sequence.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math._number_theory, komorebi_math.exceptions. Reverse package dependents (6): komorebi_math.sequences, komorebi_math.sequences.automatic, komorebi_math.sequences.catalog, komorebi_math.sequences.compiler, komorebi_math.sequences.holonomic, komorebi_math.sequences.transforms. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8.4 komorebi_math.sequences.catalog

Purpose and source. A small exact catalog of classical integer sequences. It is an ordinary module in the sequences family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/sequences/catalog.py contains 162 lines and 4,501 bytes. Source SHA-256 begins 655764bb651a0f1c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: apery_sequence, fibonacci_sequence, get_sequence, motzkin_sequence, partition_sequence, thue_morse_sequence. Its __all__ declaration contains 13 names: apery_sequence, bell_sequence, bernoulli_sequence, catalan_sequence, euler_zigzag_sequence, fibonacci_sequence, get_sequence, lucas_sequence, motzkin_sequence, partition_sequence, and 3 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.arithmetic.euler, komorebi_math.arithmetic.recurrence, komorebi_math.sequences.automatic, komorebi_math.sequences.base, komorebi_math.sequences.holonomic. Reverse package dependents (1): komorebi_math.sequences. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8.5 komorebi_math.sequences.compiler

Purpose and source. Finite sequence analysis and executable model compilation. It is an ordinary module in the sequences family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/sequences/compiler.py contains 293 lines and 12,180 bytes. Source SHA-256 begins 7c8a2dbf9deeded3.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: compile_sequence, CompiledSequence. Its __all__ declaration contains 4 names: compile_sequence, CompiledSequence, detect_linear_recurrence, recurrence_generating_function.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): komorebi_math._number_theory, komorebi_math.arithmetic.recurrence, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.sequences.automatic, komorebi_math.sequences.base, and 1 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.sequences. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8.6 komorebi_math.sequences.holonomic

Purpose and source. Exact polynomial coefficient recurrences for holonomic sequences. It is an ordinary module in the sequences family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/sequences/holonomic.py contains 178 lines and 6,725 bytes. Source SHA-256 begins 59d3301e58c9c239.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: HolonomicRecurrence. Its __all__ declaration contains 5 names: apery_recurrence, evaluate_polynomial, HolonomicRecurrence, motzkin_recurrence, Polynomial.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.sequences.base`. Reverse package dependents (3): `komorebi_math.sequences`, `komorebi_math.sequences.catalog`, `komorebi_math.sequences.compiler`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.8.7 `komorebi_math.sequences.transforms`

Purpose and source. Exact finite and lazy transformations of integer sequences. It is an ordinary module in the `sequences` family. The ledger classifies it as unmanifested implementation support. Source `src/komorebi_math/sequences/transforms.py` contains 103 lines and 3,416 bytes. Source SHA-256 begins `53d6359493989a4a`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 7 names: `binomial_transform`, `binomial_transform_values`, `cauchy_product`, `finite_difference`, `inverse_binomial_transform`, `inverse_binomial_transform_values`, `partial_sums`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math._number_theory`, `komorebi_math.exceptions`, `komorebi_math.sequences.base`. Reverse package dependents (1): `komorebi_math.sequences`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.9 Analytic: 7 modules

D.2.9.1 `komorebi_math.analytic`

Purpose and source. Cyclic analytic functions, reciprocal families, and zero diagnostics. It is the package initializer for the `analytic` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/analytic/__init__.py` contains 115 lines and 2,835 bytes. Source SHA-256 begins `a66468c72a4eeda3`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 43 names: `appell_coefficients`, `appell_polynomial`, `appell_polynomial_symbolic`, `asymptotic_positive_zero`, `congruential_inverse`, `congruential_reciprocal_coefficients`, `cyclic_addition`, `cyclic_packets`, `cyclic_product_packets`, `cyclic_project_coefficients`, and 33 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): `komorebi_math._planned`, `komorebi_math.analytic.appell`, `komorebi_math.analytic.cyclic`, `komorebi_math.analytic.reciprocal`, `komorebi_math.analytic.sections`, `komorebi_math.analytic.zeros`, and 1 more in the machine-readable ledger. Reverse package dependents (3): `komorebi_math`, `komorebi_math.arithmetic.standard_windows`, `komorebi_math.verify.analytic`. Examples (1): `cyclic_analytic.py`. Tests or test support files (2): `test_analytic_appell_zeros.py`, `test_analytic_cyclic_reciprocal.py`. Documentation files with literal module or public-route references (2): `API_INVENTORY.md`, `PUBLIC_API.md`. AST parsing and runtime import both passed in the recorded module audit.

D.2.9.2 `komorebi_math.analytic._series`

Purpose and source. Finite formal power series helpers for the analytic package. It is an ordinary module in the `analytic` family. The ledger classifies it as an internal support module. Source `src/komorebi_math/analytic/_series.py` contains 137 lines and 4,660 bytes. Source SHA-256 begins `c2741faf01809dd7`.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 8 names: `inverse_series`, `logarithmic_coefficients`, `multi-`

ply_series, positive_section_coefficients, power_series_from_log, signed_denominator_coefficients, validate_degree, validate_order.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (5): komorebi_math.analytic.appell, komorebi_math.analytic.cyclic, komorebi_math.analytic.reciprocal, komorebi_math.analytic.sections, komorebi_math.analytic.zeros. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.9.3 komorebi_math.analytic.appell

Purpose and source. Congruential reciprocal, Appell, and theta polynomial families. It is an ordinary module in the analytic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/analytic/appell.py contains 161 lines and 5,577 bytes. Source SHA-256 begins 77e09c343a4ea948.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: appell_polynomial, theta_polynomial. Its __all__ declaration contains 7 names: appell_coefficients, appell_polynomial, appell_polynomial_symbolic, congruential_inverse, congruential_reciprocal_coefficients, theta_polynomial, theta_polynomial_symbolic.

Dependencies and evidence. Direct dependency profile: optional exact extra. Direct package dependencies (3): komorebi_math.analytic._series, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.analytic. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.9.4 komorebi_math.analytic.cyclic

Purpose and source. Cyclic projection and residue packet operations for analytic series. It is an ordinary module in the analytic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/analytic/cyclic.py contains 140 lines and 4,844 bytes. Source SHA-256 begins 1fe389400de98f65.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: cyclic_project_coefficients. Its __all__ declaration contains 6 names: cyclic_packets, cyclic_product_packets, cyclic_project_coefficients, cyclic_project_value, cyclic_projection_certificate, cyclic_reconstruct.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.analytic._series, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.analytic. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.9.5 komorebi_math.analytic.reciprocal

Purpose and source. Reciprocal powers, logarithmic coefficients, and transfer tangent data. It is an ordinary module in the analytic family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/analytic/reciprocal.py contains 170 lines and 6,173 bytes. Source SHA-256 begins 50e0b6e36c23385f.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: reciprocal_coefficients, transfer_tangent. Its __all__ declaration contains 7 names: logarithmic_coefficients, reciprocal_coefficients, reciprocal_polynomial, reciprocal_semigroup_certificate, reciprocal_value, transfer_tangent, transfer_tangent_coefficients.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (5): komorebi_math.analytic._series, komorebi_math.analytic.sections, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.analytic. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.9.6 `komorebi_math.analytic.sections`

Purpose and source. Transfer exponential sections and signed cyclic differential bases. It is an ordinary module in the `analytic` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/analytic/sections.py` contains 287 lines and 9,125 bytes. Source SHA-256 begins `d33b4dcff5f0c442`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: CyclicSectionFamily, denominator, signed_section, transfer_section. Its `__all__` declaration contains 12 names: `cyclic_addition`, `CyclicSectionFamily`, `denominator`, `denominator_derivative`, `denominator_root_sum`, `section_certificate`, `signed_section`, `signed_sections`, `signed_shift_matrix`, `transfer_section`, and 2 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: optional `scientific` extra, required NumPy dependency. Direct package dependencies (5): `komorebi_math.analytic._series`, `komorebi_math.certificates`, `komorebi_math.dynamics._linalg`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (3): `komorebi_math.analytic`, `komorebi_math.analytic.reciprocal`, `komorebi_math.analytic.zeros`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.9.7 `komorebi_math.analytic.zeros`

Purpose and source. Numerical zero strings, Hadamard products, and zeta diagnostics. It is an ordinary module in the `analytic` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/analytic/zeros.py` contains 275 lines and 10,246 bytes. Source SHA-256 begins `f39a5a958e9dd837`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: CyclicDenominator, positive_zero_string. Its `__all__` declaration contains 8 names: `asymptotic_positive_zero`, `CyclicDenominator`, `hadamard_partial_product`, `positive_zero_string`, `reciprocal_coefficient_from_zeros`, `reduced_zero_zeta`, `zero_count_asymptotic`, `ZeroStringResult`.

Dependencies and evidence. Direct dependency profile: optional `scientific` extra, required NumPy dependency. Direct package dependencies (5): `komorebi_math.analytic._series`, `komorebi_math.analytic.sections`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.analytic`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10 Refinement: 10 modules

D.2.10.1 `komorebi_math.refinement`

Purpose and source. Refinement towers, weighted transfer, integral separation, and linear defects. It is the package initializer for the `refinement` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/refinement/__init__.py` contains 99 lines and 2,688 bytes. Source SHA-256 begins `86c29af7a7991527`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 43 names: `coarsen_lattice_polyphase`, `coarsen_polyphase`, `common_refinement`, `crt_many`, `crt_pair`, `CRTAddress`, `dyadic_odd_factor`, `factor_residue`, `FEATURE_KEY`, `FilteredInverseExpansion`, and 33 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (9): `komorebi_math.refinement.crt`, `komorebi_math.refinement.defects`, `komorebi_math.refinement.lattices`, `komorebi_math.refinement.polyphase`, `komorebi_math.refinement.residue`, `komorebi_math.refinement.smith`, and 3 more in the machine-readable ledger. Reverse package dependents (4): `komorebi_math`, `komorebi_math.qualification`, `komorebi_math.verify.refinement`, `komorebi_math.verify.stabilization`. Examples (3): `block15_polyphase_refinement.py`, `block21_public_capability_tour.py`, `refinement_pipeline.py`. Tests or test support files (10): `test_block15_persistence.py`, `test_block15_polyphase_refinement.py`, `test_block15_stable_api.py`, `test_block16_release_qualification.py`, `test_block17_upgrade_contract.py`, and 5 more

in the machine-readable ledger. Documentation files with literal module or public-route references (2): `API_INVENTORY.md`, `BLOCK_15_RELEASE.md`. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.2 `komorebi_math.refinement.crt`

Purpose and source. Chinese remainder addresses for residue packet systems. It is an ordinary module in the `refinement` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/refinement/crt.py` contains 128 lines and 5,280 bytes. Source SHA-256 begins `72cf5291bf5a9e82`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: crt_many, crt_pair. Its `__all__` declaration contains 5 names: `crt_many`, `crt_pair`, `CRTAddress`, `dyadic_odd_factor`, `factor_residue`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.refinement`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.3 `komorebi_math.refinement.defects`

Purpose and source. Linear refinement defects and their propagated identities. It is an ordinary module in the `refinement` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/refinement/defects.py` contains 302 lines and 13,618 bytes. Source SHA-256 begins `d256db55d9bb6fa3`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: LinearRefinementDefect. Its `__all__` declaration contains 2 names: `LinearRefinementDefect`, `multilevel_defect`.

Dependencies and evidence. Direct dependency profile: optional `exact` extra, optional `scientific` extra, required NumPy dependency. Direct package dependencies (4): `komorebi_math.backends`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (1): `komorebi_math.refinement`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.4 `komorebi_math.refinement.lattices`

Purpose and source. Integral packet separation and lattice gluing modules. It is an ordinary module in the `refinement` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/refinement/lattices.py` contains 290 lines and 11,522 bytes. Source SHA-256 begins `65fa26dd374a3c39`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: LatticePacketData. Its `__all__` declaration contains 4 names: `GluingModule`, `LatticePacketData`, `PrecisionDelay`, `refinement_weight_monotonicity`.

Dependencies and evidence. Direct dependency profile: optional `exact` extra. Direct package dependencies (5): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`, `komorebi_math.refinement.smith`. Reverse package dependents (1): `komorebi_math.refinement`. Examples (1): `exact_lattice_separation.py`. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.5 `komorebi_math.refinement.polyphase`

Purpose and source. Canonical finite polyphase refinement and coarsening. It is an ordinary module in the `refinement` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/refinement/polyphase.py` contains 997 lines and 40,482 bytes. Source SHA-256 begins `013f8f23a15f2443`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 12 stable, 0 beta, and 0 research. Linked cards: coarsen_lattice_polyphase, coarsen_polyphase, lattice_polyphase_coarsen, lattice_polyphase_refine, LatticePolyphaseRefinement, polyphase_coarsen, polyphase_refine, polyphase_refinement_certificate, PolyphaseRefinement, PolyphaseRefinementTower, and 2 more in the machine-readable ledger. Its `__all__` declaration contains 9 names: `coarsen_lattice_polyphase`, `coarsen_polyphase`, `LatticePolyphase`

Refinement, polyphase_refinement_certificate, PolyphaseCoordinateRecord, PolyphaseRefinement, PolyphaseRefinementTower, refine_lattice_polyphase, refine_polyphase.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.arithmetic.polyphase, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.refinement.residue, komorebi_math.signals.polyphase. Reverse package dependents (7): komorebi_math.arithmetic.polyphase, komorebi_math.refinement, komorebi_math.refinement.portable, komorebi_math.refinement.residue, komorebi_math.signals.polyphase, komorebi_math.stable, and 1 more in the machine-readable ledger. Examples (0): none. Tests or test support files (2): test_block15_polyphase_refinement.py, test_block15_stable_api.py. Documentation files with literal module or public-route references (1): BLOCK_15_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.6 komorebi_math.refinement.portable

Purpose and source. Trusted portable codecs for finite polyphase and refinement records. It is an ordinary module in the refinement family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/refinement/portable.py contains 177 lines and 5,979 bytes. Source SHA-256 begins 7b2bd87214fe500d.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: register_refinement_codecs.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): komorebi_math.arithmetic.polyphase, komorebi_math.exceptions, komorebi_math.export.persistence, komorebi_math.refinement.polyphase, komorebi_math.refinement.residue, komorebi_math.signals.polyphase. Reverse package dependents (1): komorebi_math.export.persistence. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.7 komorebi_math.refinement.residue

Purpose and source. Residue and polyphase packet coordinates. It is an ordinary module in the refinement family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/refinement/residue.py contains 192 lines and 7,728 bytes. Source SHA-256 begins 8287237612523129.

Surface and ownership. API classification: API-manifested implementation owner. It owns 7 manifest cards: 5 stable, 0 beta, and 2 research. Linked cards: nested_residue_address, nested_residue_analysis, residue_analyze, residue_synthesize, ResidueCoordinates, residue_analyze, residue_packet_system. Its __all__ declaration contains 7 names: nested_residue_address, nested_residue_analysis, packet_coordinates_from_residues, residue_analyze, residue_packet_system, residue_synthesize, ResidueCoordinates.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (5): komorebi_math.backends, komorebi_math.core.packets, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.refinement.polyphase. Reverse package dependents (4): komorebi_math.refinement, komorebi_math.refinement.polyphase, komorebi_math.refinement.portable, komorebi_math.stable. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.8 komorebi_math.refinement.smith

Purpose and source. Smith coordinates and congruence solving over prime-power rings. It is an ordinary module in the refinement family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/refinement/smith.py contains 324 lines and 12,783 bytes. Source SHA-256 begins fa6238011f016a44.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: SmithCongruenceProblem. Its __all__ declaration contains 6 names: padic_valuation, rational_padic_valuation, smith_decomposition, SmithCongruenceProblem, SmithCongruenceSolution, SmithDecomposition.

Dependencies and evidence. Direct dependency profile: optional exact extra. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Re-

verse package dependents (3): komorebi_math.refinement, komorebi_math.refinement.lattices, komorebi_math.refinement.weighted. Examples (1): exact_lattice_separation.py. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.9 komorebi_math.refinement.towers

Purpose and source. Exact packet refinements and finite refinement towers. It is an ordinary module in the refinement family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/refinement/towers.py contains 266 lines and 12,635 bytes. Source SHA-256 begins 03928347574f0f76.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 3 stable, 0 beta, and 3 research. Linked cards: common_refinement, PacketRefinement, RefinementTower, common_refinement, PacketRefinement, RefinementTower. Its __all__ declaration contains 3 names: common_refinement, PacketRefinement, RefinementTower.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.core.operators, komorebi_math.core.packets, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math.refinement, komorebi_math.stable, komorebi_math.unified. Examples (1): refinement_pipeline.py. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.10.10 komorebi_math.refinement.weighted

Purpose and source. Weighted packet transfers and filtered inverse expansions. It is an ordinary module in the refinement family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/refinement/weighted.py contains 403 lines and 17,163 bytes. Source SHA-256 begins 94c13dd4ed26909c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: WeightedTransferEdge, WeightedTransferGraph. Its __all__ declaration contains 4 names: FilteredInverseExpansion, WeightedPath, WeightedTransferEdge, WeightedTransferGraph.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (7): komorebi_math._number_theory, komorebi_math.backends, komorebi_math.certificates, komorebi_math.core.packets, komorebi_math.exceptions, komorebi_math.provenance, and 1 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.refinement. Examples (1): refinement_pipeline.py. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11 Coordinates: 24 modules

D.2.11.1 komorebi_math.coordinates

Purpose and source. General exact and numerical coordinate calculus across Komorebi Math. It is the package initializer for the coordinates family. The ledger classifies it as a canonical API namespace facade. Source src/komorebi_math/coordinates/__init__.py contains 521 lines and 14,575 bytes. Source SHA-256 begins 94c38b190c95bbea.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 237 names: affine_basis_transform, affine_polynomial, affine_substitution_coordinate_operator, affine_substitution_transform, AffineCoordinateTransform, AnalysisSynthesisBlocks, AnalysisSynthesisCoefficientBlocks, AnalysisSynthesisGauge, AnalysisSynthesisMap, AnalysisSynthesisSystem, and 227 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (23): komorebi_math.coordinates.affine, komorebi_math.coordinates.analysis_synthesis, komorebi_math.coordinates.basis, komorebi_math.coordinates.budget, komorebi_math.coordinates.calculus, komorebi_math.coordinates.classical, and 17 more in the machine-readable ledger. Reverse package dependents (9): komorebi_math, komorebi_math.cli.main, komorebi_math.golden, komorebi_math.qualification,

komorebi_math.stable, komorebi_math.verify.coordinates, and 3 more in the machine-readable ledger. Examples (9): block19_measure_integration_worked_example.py, block21_public_capability_tour.py, classical_coordinate_families.py, coordinate_calculus.py, euler_to_fibonacci_coordinates.py, and 4 more in the machine-readable ledger. Tests or test support files (20): test_block14_cli_api.py, test_block16_analysis_synthesis.py, test_block16_contracts.py, test_block18_frame_algebra.py, test_block19_integration.py, and 15 more in the machine-readable ledger. Documentation files with literal module or public-route references (6): API_COMPATIBILITY_0.14.md, API_INVENTORY.md, BLOCK_14_RELEASE.md, COMPANION_COORDINATE_CALCULUS.md, GENERAL_COORDINATE_ATLAS.md, and 1 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.2 komorebi_math.coordinates.affine

Purpose and source. Exact affine, homogeneous, and barycentric coordinate changes. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/affine.py contains 278 lines and 10,891 bytes. Source SHA-256 begins 758d3b5f1ea53c60.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: AffineCoordinateTransform, affine_basis_transform, AffineCoordinateTransform, BarycentricCoordinateSystem, translation_transform. Its __all__ declaration contains 4 names: affine_basis_transform, AffineCoordinateTransform, BarycentricCoordinateSystem, translation_transform.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.coordinates.exact, komorebi_math.exceptions. Reverse package dependents (4): komorebi_math, komorebi_math.coordinates, komorebi_math.coordinates.portable, komorebi_math.verify.coordinates. Examples (1): formal_affine_coordinate_changes.py. Tests or test support files (2): test_coordinates_general_affine_formal.py, test_coordinates_general_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.3 komorebi_math.coordinates.analysis_synthesis

Purpose and source. General finite analysis-synthesis systems. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/analysis_synthesis.py contains 384 lines and 15,752 bytes. Source SHA-256 begins 08f1edf9d69ee112.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 2 stable, 0 beta, and 4 research. Linked cards: AnalysisSynthesisBlocks, AnalysisSynthesisSystem, AnalysisSynthesisBlocks, AnalysisSynthesisSystem, AnalysisSynthesisBlocks, AnalysisSynthesisSystem. Its __all__ declaration contains 2 names: AnalysisSynthesisBlocks, AnalysisSynthesisSystem.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (10): komorebi_math, komorebi_math.coordinates, komorebi_math.coordinates.frame_algebra, komorebi_math.coordinates.portable, komorebi_math.integration.adapters, komorebi_math.qualification, and 4 more in the machine-readable ledger. Examples (2): block16_analysis_synthesis.py, block21_public_capability_tour.py. Tests or test support files (4): test_block16_analysis_synthesis.py, test_block16_contracts.py, test_block18_frame_algebra.py, test_block19_integration.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.4 komorebi_math.coordinates.basis

Purpose and source. Arbitrary finite bases and exact coordinate atlases. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/basis.py contains 535 lines and 21,004 bytes. Source SHA-256 begins 9f7351fd968c2c8c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 20 manifest cards: 4 stable, 0 beta, and 16 research. Linked cards: basis_from_matrix, CoordinateAtlas, FiniteBasis, standard_basis, basis_from_matrix, CoordinateAtlas, CoordinateSystem, FiniteBasis, standard_basis, AtlasPath, and 10 more in the machine-readable ledger. Its __all__ declaration contains 11 names: AtlasPath, basis_from_matrix, CommutingDiagramCheck, CoordinateAtlas, CoordinateSystem, direct_sum_basis, FiniteBasis, permutation_transform, scaling_transform, standard_basis, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.coordinates.budget`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.transform`, `komorebi_math.exceptions`. Reverse package dependents (12): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.coordinates`, `komorebi_math.coordinates.classical`, `komorebi_math.coordinates.families`, `komorebi_math.coordinates.packet`, and 6 more in the machine-readable ledger. Examples (1): `general_coordinate_atlas.py`. Tests or test support files (2): `test_coordinates_general_basis.py`, `test_coordinates_general_persistence.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.5 `komorebi_math.coordinates.budget`

Purpose and source. Explicit resource contracts for finite coordinate computations. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/budget.py` contains 71 lines and 3,029 bytes. Source SHA-256 begins `0d9e7122304df293`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: CoordinateBudget, CoordinateBudget, DEFAULT_COORDINATE_BUDGET. Its `__all__` declaration contains 2 names: `CoordinateBudget`, `DEFAULT_COORDINATE_BUDGET`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.exceptions`. Reverse package dependents (13): `komorebi_math`, `komorebi_math.coordinates`, `komorebi_math.coordinates.basis`, `komorebi_math.coordinates.calculus`, `komorebi_math.coordinates.classical`, `komorebi_math.coordinates.combinatorial`, and 7 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.6 `komorebi_math.coordinates.calculus`

Purpose and source. Operator matrices in arbitrary polynomial coordinates. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/calculus.py` contains 314 lines and 10,152 bytes. Source SHA-256 begins `7156398767a48211`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 11 manifest cards: 0 stable, 0 beta, and 11 research. Linked cards: PolynomialCoordinateOperator, affine_substitution_coordinate_operator, derivative_coordinate_operator, finite_difference_coordinate_operator, integral_coordinate_operator, multiplication_coordinate_operator, operator_commutator, polynomial_integral, polynomial_operator, PolynomialCoordinateOperator, and 1 more in the machine-readable ledger. Its `__all__` declaration contains 10 names: `affine_substitution_coordinate_operator`, `derivative_coordinate_operator`, `finite_difference_coordinate_operator`, `integral_coordinate_operator`, `multiplication_coordinate_operator`, `operator_commutator`, `polynomial_integral`, `polynomial_operator`, `PolynomialCoordinateOperator`, `transport_polynomial_operator`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): `komorebi_math.certificates`, `komorebi_math.coordinates.budget`, `komorebi_math.coordinates.classical`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.polynomials`, `komorebi_math.coordinates.tensor`, and 1 more in the machine-readable ledger. Reverse package dependents (5): `komorebi_math`, `komorebi_math.coordinates`, `komorebi_math.coordinates.portable`, `komorebi_math.integration.coordinates`, `komorebi_math.verify.coordinates`. Examples (1): `classical_coordinate_families.py`. Tests or test support files (2): `test_coordinates_general_calculus.py`, `test_coordinates_general_persistence.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.7 `komorebi_math.coordinates.classical`

Purpose and source. Classical polynomial families and interpolation coordinate systems. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/classical.py` contains 657 lines and 21,840 bytes. Source SHA-256 begins `4a44df81afb429df`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 45 manifest cards: 1 stable, 0 beta, and 44 research. Linked cards: get_polynomial_family, classical_polynomial_catalog, get_polynomial_family, affine_polynomial, affine_substitution_transform, appell_polynomial, appell_polynomial_

family, bernoulli_number, bernoulli_polynomial, bernoulli_polynomial_family, and 35 more in the machine-readable ledger. Its `__all__` declaration contains 42 names: `affine_polynomial`, `affine_substitution_transform`, `appell_polynomial`, `appell_polynomial_family`, `bernoulli_number`, `bernoulli_polynomial`, `bernoulli_polynomial_family`, `bernstein_basis`, `bernstein_polynomial`, `binomial_polynomial`, and 32 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): `komorebi_math.coordinates.basis`, `komorebi_math.coordinates.budget`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.polynomials`, `komorebi_math.coordinates.transform`, `komorebi_math.exceptions`. Reverse package dependents (8): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.coordinates`, `komorebi_math.coordinates.calculus`, `komorebi_math.golden`, `komorebi_math.stable`, and 2 more in the machine-readable ledger. Examples (1): `classical_coordinate_families.py`. Tests or test support files (3): `test_block19_integration.py`, `test_coordinates_general_calculus.py`, `test_coordinates_general_classical.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.8 `komorebi_math.coordinates.combinatorial`

Purpose and source. Exact combinatorial coordinate transforms for finite sequences. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/combinatorial.py` contains 381 lines and 12,049 bytes. Source SHA-256 begins `bb0a73e44deecfd2`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 19 manifest cards: 1 stable, 0 beta, and 18 research. Linked cards: forward_difference_transform, binomial_transform, forward_difference_transform, binomial_transform, divisor_zeta_transform, falling_factorial_to_monomial_transform, forward_difference_transform, lah_number, mobius_integer, monomial_to_falling_factorial_transform, and 9 more in the machine-readable ledger. Its `__all__` declaration contains 16 names: `binomial_transform`, `divisor_zeta_transform`, `falling_factorial_to_monomial_transform`, `forward_difference_transform`, `lah_number`, `mobius_integer`, `monomial_to_falling_factorial_transform`, `monomial_to_rising_factorial_transform`, `newton_evaluation_transform`, `rising_factorial_to_monomial_transform`, and 6 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math.coordinates.budget`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.transform`, `komorebi_math.exceptions`. Reverse package dependents (6): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.coordinates`, `komorebi_math.golden`, `komorebi_math.stable`, `komorebi_math.verify.coordinates`. Examples (0): none. Tests or test support files (2): `test_coordinates_general_combinatorial.py`, `test_coordinates_general_tensor_modular.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.9 `komorebi_math.coordinates.exact`

Purpose and source. Small exact linear algebra over the rational numbers. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/exact.py` contains 357 lines and 11,758 bytes. Source SHA-256 begins `730ffa5075436ef2`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 19 manifest cards: 0 stable, 0 beta, and 19 research. Linked cards: as_matrix, as_vector, determinant, ExactLinearSystem, identity_matrix, inverse_matrix, matrix_add, matrix_from_columns, matrix_multiply, matrix_power, and 9 more in the machine-readable ledger. Its `__all__` declaration contains 24 names: `as_matrix`, `as_vector`, `columns`, `determinant`, `ExactLinearSystem`, `identity_matrix`, `inverse_matrix`, `kronecker`, `Matrix`, `matrix_add`, and 14 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.exceptions`. Reverse package dependents (27): `komorebi_math.coordinates`, `komorebi_math.coordinates.affine`, `komorebi_math.coordinates.basis`, `komorebi_math.coordinates.calculus`, `komorebi_math.coordinates.classical`, `komorebi_math.coordinates.combinatorial`, and 21 more in the machine-readable ledger. Examples (0): none. Tests or test support files (9): `test_block18_frame_algebra.py`, `test_coordinates_exact.py`, `test_coordinates_general_affine_formal.py`, `test_coordinates_general_classical.py`, `test_coordinates_general_combinatorial.py`, and 4 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.10 komorebi_math.coordinates.families

Purpose and source. Named and custom recurrence coordinate families. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/families.py contains 238 lines and 8,746 bytes. Source SHA-256 begins 13eb428d864cbd31.

Surface and ownership. API classification: API-manifested implementation owner. It owns 14 manifest cards: 0 stable, 0 beta, and 14 research. Linked cards: get_recurrence_model, recurrence_model_catalog, RecurrenceModel, custom_recurrence_model, fibonacci_recurrence_model, get_recurrence_model, jacobsthal_recurrence_model, lucas_recurrence_model, padovan_recurrence_model, pell_recurrence_model, and 4 more in the machine-readable ledger. Its __all__ declaration contains 11 names: custom_recurrence_model, fibonacci_recurrence_model, get_recurrence_model, jacobsthal_recurrence_model, lucas_recurrence_model, padovan_recurrence_model, pell_recurrence_model, recurrence_model_catalog, RecurrenceModel, sequence_coordinates_between_models, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.coordinates.basis, komorebi_math.coordinates.exact, komorebi_math.coordinates.recurrence, komorebi_math.coordinates.transform, komorebi_math.exceptions. Reverse package dependents (5): komorebi_math, komorebi_math.cli.main, komorebi_math.coordinates, komorebi_math.coordinates.portable, komorebi_math.verify.coordinates. Examples (1): recurrence_state_coordinate_atlas.py. Tests or test support files (2): test_coordinates_general_families_state.py, test_coordinates_general_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.11 komorebi_math.coordinates.formal

Purpose and source. Exact formal changes of variable and finite jet coordinates. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/formal.py contains 275 lines and 11,000 bytes. Source SHA-256 begins 2c12755281dc4433.

Surface and ownership. API classification: API-manifested implementation owner. It owns 7 manifest cards: 2 stable, 0 beta, and 5 research. Linked cards: formal_coordinate_from_iterable, FormalCoordinateChange, FormalCoordinateChange, compose_ordinary_series, formal_coordinate_from_iterable, FormalCoordinateChange, identity_formal_coordinate. Its __all__ declaration contains 4 names: compose_ordinary_series, formal_coordinate_from_iterable, FormalCoordinateChange, identity_formal_coordinate.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.coordinates.budget, komorebi_math.coordinates.exact, komorebi_math.coordinates.transform, komorebi_math.exceptions. Reverse package dependents (7): komorebi_math, komorebi_math.cli.main, komorebi_math.coordinates, komorebi_math.coordinates.portable, komorebi_math.golden, komorebi_math.stable, and 1 more in the machine-readable ledger. Examples (1): formal_affine_coordinate_changes.py. Tests or test support files (2): test_coordinates_general_affine_formal.py, test_coordinates_general_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.12 komorebi_math.coordinates.frame_algebra

Purpose and source. Finite coefficient-space closure for analysis-synthesis systems. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/frame_algebra.py contains 1,024 lines and 41,467 bytes. Source SHA-256 begins cb9f91235c866b83.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 0 stable, 0 beta, and 12 research. Linked cards: AnalysisSynthesisCoefficientBlocks, AnalysisSynthesisGauge, AnalysisSynthesisMap, CoefficientPartition, ExactAnalysisSynthesisMap, ExactAnalysisSynthesisSystem, AnalysisSynthesisCoefficientBlocks, AnalysisSynthesisGauge, AnalysisSynthesisMap, CoefficientPartition, and 2 more in the machine-readable ledger. Its __all__ declaration contains 6 names: AnalysisSynthesisCoefficientBlocks, AnalysisSynthesisGauge, AnalysisSynthesisMap, CoefficientPartition, ExactAnalysisSynthesisMap, ExactAnalysisSynthesisSystem.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.coordinates.analysis_synthesis`, `komorebi_math.coordinates.exact`, `komorebi_math.exceptions`. Reverse package dependents (3): `komorebi_math`, `komorebi_math.coordinates`, `komorebi_math.verify.frame_algebra`. Examples (0): none. Tests or test support files (1): `test_block18_frame_algebra.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.13 `komorebi_math.coordinates.modular`

Purpose and source. Coordinate transforms over finite prime fields. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/modular.py` contains 249 lines and 9,569 bytes. Source SHA-256 begins `529be182bb6f4436`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: FiniteFieldCoordinateTransform, FiniteFieldCoordinateTransform, reduce_exact_transform_mod_prime. Its `__all__` declaration contains 4 names: `FiniteFieldCoordinateTransform`, `ModularMatrix`, `ModularVector`, `reduce_exact_transform_mod_prime`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.transform`, `komorebi_math.exceptions`. Reverse package dependents (4): `komorebi_math`, `komorebi_math.coordinates`, `komorebi_math.coordinates.portable`, `komorebi_math.verify.coordinates`. Examples (0): none. Tests or test support files (2): `test_coordinates_general_persistence.py`, `test_coordinates_general_tensor_modular.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.14 `komorebi_math.coordinates.normalized`

Purpose and source. Coordinate changes for normalized monomial generating functions. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/normalized.py` contains 120 lines and 3,376 bytes. Source SHA-256 begins `e92de85740e231a3`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: normalization_change_transform, apply_lowering_polynomial, convert_normalized_coefficients, normalization_change_transform. Its `__all__` declaration contains 7 names: `apply_lowering_polynomial`, `convert_normalized_coefficients`, `exponential_basis`, `fibonacci_factorial_basis`, `normalization_change_transform`, `NormalizedBasis`, `ordinary_basis`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): `komorebi_math.coordinates.budget`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.transform`, `komorebi_math.exceptions`, `komorebi_math.generating`, `komorebi_math.generating.basis`. Reverse package dependents (5): `komorebi_math`, `komorebi_math.coordinates`, `komorebi_math.coordinates.operators`, `komorebi_math.coordinates.recurrence`, `komorebi_math.verify.coordinates`. Examples (0): none. Tests or test support files (1): `test_coordinates_normalized_persistence.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.15 `komorebi_math.coordinates.numeric`

Purpose and source. Numerical spectral and orthogonal coordinate transforms. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/numeric.py` contains 352 lines and 13,128 bytes. Source SHA-256 begins `868983da6260f318`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 1 stable, 0 beta, and 9 research. Linked cards: NumericCoordinateTransform, discrete_fourier_transform, NumericCoordinateTransform, discrete_cosine_transform, discrete_fourier_transform, haar_wavelet_transform, modal_coordinate_system, ModalCoordinateSystem, NumericCoordinateTransform, walsh_hadamard_transform. Its `__all__` declaration contains 7 names: `discrete_cosine_transform`, `discrete_fourier_transform`, `haar_wavelet_transform`, `modal_coordinate_system`, `ModalCoordinateSystem`, `NumericCoordinateTransform`, `walsh_hadamard_transform`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (6): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.coordinates`, `komorebi_math.coordinates.portable`, `komorebi_math.stable`, `komorebi_math.verify.coordinates`. Examples (1): `spectral_packet_coordinates.py`. Tests or test support files (2): `test_coordinates_general_numeric_packet.py`, `test_coordinates_general_persistence.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.16 `komorebi_math.coordinates.operators`

Purpose and source. Polynomial identities for lowering and recurrence defect operators. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/operators.py` contains 148 lines and 5,396 bytes. Source SHA-256 begins `339b6623ba6283c9`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 7 manifest cards: 0 stable, 0 beta, and 7 research. Linked cards: bezout_defect_identity, BezoutDefectIdentity, ShiftPolynomial, bezout_defect_identity, BezoutDefectIdentity, polynomial_extended_gcd, ShiftPolynomial. Its `__all__` declaration contains 4 names: `bezout_defect_identity`, `BezoutDefectIdentity`, `polynomial_extended_gcd`, `ShiftPolynomial`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.normalized`, `komorebi_math.coordinates.polynomials`, `komorebi_math.exceptions`. Reverse package dependents (4): `komorebi_math`, `komorebi_math.coordinates`, `komorebi_math.coordinates.portable`, `komorebi_math.verify.coordinates`. Examples (0): none. Tests or test support files (1): `test_coordinates_operators.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.17 `komorebi_math.coordinates.packet`

Purpose and source. Exact packet, residue, and tensor-index coordinate permutations. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/packet.py` contains 178 lines and 6,100 bytes. Source SHA-256 begins `e3dd0f89f6266680`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 0 stable, 0 beta, and 10 research. Linked cards: residue_class_transform, chinese_remainder_order, chinese_remainder_transform, digit_reversal_order, digit_reversal_transform, residue_class_order, residue_class_transform, sorted_coordinate_transform, tensor_axis_permutation_order, tensor_axis_permutation_transform. Its `__all__` declaration contains 9 names: `chinese_remainder_order`, `chinese_remainder_transform`, `digit_reversal_order`, `digit_reversal_transform`, `residue_class_order`, `residue_class_transform`, `sorted_coordinate_transform`, `tensor_axis_permutation_order`, `tensor_axis_permutation_transform`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math.coordinates.basis`, `komorebi_math.coordinates.transform`, `komorebi_math.exceptions`. Reverse package dependents (4): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.coordinates`, `komorebi_math.verify.coordinates`. Examples (1): `spectral_packet_coordinates.py`. Tests or test support files (1): `test_coordinates_general_numeric_packet.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.18 `komorebi_math.coordinates.polynomials`

Purpose and source. Connection coefficients for graded polynomial families. It is an ordinary module in the `coordinates` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/coordinates/polynomials.py` contains 389 lines and 13,184 bytes. Source SHA-256 begins `4b891dbe1541765e`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 26 manifest cards: 1 stable, 0 beta, and 25 research. Linked cards: connection_transform, connection_transform, euler_to_fibonacci_transform, operator_change_of_coordinates, PolynomialFamily, connection_transform, derivative_operator_in_family, euler_polynomial, euler_polynomial_at_zero, euler_polynomial_family, and 16 more in the machine-readable ledger. Its `__all__` declaration contains 21 names: `connection_transform`, `derivative_operator_in_family`,

euler_polynomial, euler_polynomial_at_zero, euler_to_fibonacci_coefficient, euler_to_fibonacci_transform, fibonacci_companion_power, fibonacci_polynomial, fibonacci_polynomial_family, monomial_polynomial_family, and 11 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.coordinates.budget, komorebi_math.coordinates.exact, komorebi_math.coordinates.transform, komorebi_math.exceptions. Reverse package dependents (13): komorebi_math, komorebi_math.cli.main, komorebi_math.coordinates, komorebi_math.coordinates.calculus, komorebi_math.coordinates.classical, komorebi_math.coordinates.operators, and 7 more in the machine-readable ledger. Examples (3): block19_measure_integration_worked_example.py, classical_coordinate_families.py, coordinate_calculus.py. Tests or test support files (5): test_block19_integration.py, test_coordinates_general_calculus.py, test_coordinates_general_classical.py, test_coordinates_operators.py, test_coordinates_polynomials.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.19 komorebi_math.coordinates.portable

Purpose and source. Trusted portable codecs for finite coordinate-calculus records. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/portable.py contains 722 lines and 23,549 bytes. Source SHA-256 begins 9951aea34982c110.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: load_coordinate_object, save_coordinate_object, load_coordinate_object, load_coordinate_record, load_transform, register_coordinate_codecs, save_coordinate_object, save_coordinate_record, save_transform. Its __all__ declaration contains 7 names: load_coordinate_object, load_coordinate_record, load_transform, register_coordinate_codecs, save_coordinate_object, save_coordinate_record, save_transform.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (17): komorebi_math.coordinates.affine, komorebi_math.coordinates.analysis_synthesis, komorebi_math.coordinates.basis, komorebi_math.coordinates.budget, komorebi_math.coordinates.calculus, komorebi_math.coordinates.exact, and 11 more in the machine-readable ledger. Reverse package dependents (4): komorebi_math, komorebi_math.coordinates, komorebi_math.export.persistence, komorebi_math.verify.coordinates. Examples (0): none. Tests or test support files (2): test_coordinates_general_persistence.py, test_coordinates_normalized_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.20 komorebi_math.coordinates.realization

Purpose and source. Finite-dimensional realizations, observability, and intertwiners. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/realization.py contains 372 lines and 13,139 bytes. Source SHA-256 begins c120c7b5c75b6614.

Surface and ownership. API classification: API-manifested implementation owner. It owns 15 manifest cards: 0 stable, 0 beta, and 15 research. Linked cards: intertwiner_space, IntertwinerSpace, LinearRealization, observability_matrix, recover_initial_state, StateRecovery, cyclic_krylov_matrix, intertwiner_space, IntertwinerSpace, LinearRealization, and 5 more in the machine-readable ledger. Its __all__ declaration contains 9 names: cyclic_krylov_matrix, intertwiner_space, IntertwinerSpace, LinearRealization, observability_matrix, realization_defect, recover_initial_state, similarity_from_cyclic_vectors, StateRecovery.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.coordinates.budget, komorebi_math.coordinates.exact, komorebi_math.coordinates.recurrence, komorebi_math.exceptions. Reverse package dependents (4): komorebi_math, komorebi_math.coordinates, komorebi_math.coordinates.portable, komorebi_math.verify.coordinates. Examples (0): none. Tests or test support files (1): test_coordinates_realization.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.21 komorebi_math.coordinates.recurrence

Purpose and source. Universal defect coordinates for finite companion recurrences. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/recurrence.py contains 386 lines and 12,796 bytes. Source SHA-256 begins 38fe5570bf0b632e.

Surface and ownership. API classification: API-manifested implementation owner. It owns 20 manifest cards: 0 stable, 0 beta, and 20 research. Linked cards: analyze_recurrence_coordinates, companion_matrix, coordinate_change_between_recurrences, euler_fibonacci_coordinates, RecurrenceCoordinateRecord, variation_of_constants_prefix, analyze_recurrence_coordinates, apply_recurrence_defect, companion_matrix, coordinate_change_between_recurrences, and 10 more in the machine-readable ledger. Its __all__ declaration contains 15 names: analyze_recurrence_coordinates, apply_recurrence_defect, companion_matrix, coordinate_change_between_recurrences, defect_green_weights, euler_fibonacci_coordinates, fibonacci_numbers, recurrence_analysis_transform, recurrence_polynomial, recurrence_synthesis_transform, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): komorebi_math.arithmetic.recurrence, komorebi_math.certificates, komorebi_math.coordinates.budget, komorebi_math.coordinates.exact, komorebi_math.coordinates.normalized, komorebi_math.coordinates.transform, and 1 more in the machine-readable ledger. Reverse package dependents (8): komorebi_math, komorebi_math.cli.main, komorebi_math.coordinates, komorebi_math.coordinates.families, komorebi_math.coordinates.portable, komorebi_math.coordinates.realization, and 2 more in the machine-readable ledger. Examples (3): block21_public_capability_tour.py, coordinate_calculus.py, euler_to_fibonacci_coordinates.py. Tests or test support files (4): test_coordinates_normalized_persistence.py, test_coordinates_polynomials.py, test_coordinates_realization.py, test_coordinates_recurrence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.22 komorebi_math.coordinates.state_space

Purpose and source. Exact state-space coordinate changes and canonical finite realizations. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/state_space.py contains 340 lines and 12,616 bytes. Source SHA-256 begins dbcf5a293e5a4dd0.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 0 stable, 0 beta, and 10 research. Linked cards: StateSpaceModel, certify_state_coordinate_change, controllability_basis, controllability_coordinate_transform, controllability_matrix, observability_block_matrix, observability_coordinate_transform, siso_state_space, StateSpaceCoordinateCertificate, StateSpaceModel. Its __all__ declaration contains 9 names: certify_state_coordinate_change, controllability_basis, controllability_coordinate_transform, controllability_matrix, observability_block_matrix, observability_coordinate_transform, siso_state_space, StateSpaceCoordinateCertificate, StateSpaceModel.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): komorebi_math.certificates, komorebi_math.coordinates.basis, komorebi_math.coordinates.exact, komorebi_math.coordinates.tensor, komorebi_math.coordinates.transform, komorebi_math.exceptions. Reverse package dependents (4): komorebi_math, komorebi_math.coordinates, komorebi_math.coordinates.portable, komorebi_math.verify.coordinates. Examples (1): recurrence_state_coordinate_atlas.py. Tests or test support files (2): test_coordinates_general_families_state.py, test_coordinates_general_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.23 komorebi_math.coordinates.tensor

Purpose and source. Transport of operators, forms, and tensor components between bases. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/tensor.py contains 229 lines and 7,624 bytes. Source SHA-256 begins 2b882d2e43168d65.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 0 stable, 0 beta, and 12 research. Linked cards: tensor_coordinate_transform, contragredient_transform, coordinate_pairing, direct_sum_transform, pairing_invariant, tensor_coordinate_transform, tensor_product_transform, transport_bilinear_form, transport_covector, transport_operator, and 2 more in the machine-readable ledger. Its __

all__ declaration contains 12 names: contragredient_transform, coordinate_pairing, direct_sum_transform, pairing_invariant, tensor_coordinate_transform, tensor_product_transform, transport_bilinear_form, transport_covector, transport_operator, transport_rectangular_operator, and 2 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.coordinates.exact, komorebi_math.coordinates.transform, komorebi_math.exceptions. Reverse package dependents (5): komorebi_math, komorebi_math.coordinates, komorebi_math.coordinates.calculus, komorebi_math.coordinates.state_space, komorebi_math.verify.coordinates. Examples (0): none. Tests or test support files (1): test_coordinates_general_tensor_modular.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.11.24 komorebi_math.coordinates.transform

Purpose and source. Composable exact coordinate transformations. It is an ordinary module in the coordinates family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/coordinates/transform.py contains 154 lines and 5,382 bytes. Source SHA-256 begins 1e02b12f4797006d.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 2 stable, 0 beta, and 3 research. Linked cards: CoordinateTransform, ExactCoordinateTransform, CoordinateTransform, CoordinateTransform, ExactCoordinateTransform. Its __all__ declaration contains 2 names: CoordinateTransform, ExactCoordinateTransform.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.coordinates.exact, komorebi_math.exceptions. Reverse package dependents (17): komorebi_math, komorebi_math.coordinates, komorebi_math.coordinates.basis, komorebi_math.coordinates.classical, komorebi_math.coordinates.combinatorial, komorebi_math.coordinates.families, and 11 more in the machine-readable ledger. Examples (0): none. Tests or test support files (5): test_block14_cli_api.py, test_block16_analysis_synthesis.py, test_coordinates_general_basis.py, test_coordinates_general_persistence.py, test_coordinates_general_tensor_modular.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12 Generating: 22 modules

D.2.12.1 komorebi_math.generating

Purpose and source. Normalized generating functions, local masks, and arithmetic compilers. It is the package initializer for the generating family. The ledger classifies it as a canonical API namespace facade. Source src/komorebi_math/generating/__init__.py contains 451 lines and 12,061 bytes. Source SHA-256 begins b936240b6714f457.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 181 names: additive_series, algebraic_function, AlgebraicGFGuess, analytic_mahler_product, AnalyticMaskApproximation, apery_numbers, audit_apery_supercongruence, audit_factorial_power_digit_algebra, audit_factorial_power_packet_convolution, audit_generalized_bell_digit_sum, and 171 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (21): komorebi_math.generating.adapters, komorebi_math.generating.basis, komorebi_math.generating.bell, komorebi_math.generating.budget, komorebi_math.generating.cartier, komorebi_math.generating.closed_forms, and 15 more in the machine-readable ledger. Reverse package dependents (6): komorebi_math, komorebi_math.cli.main, komorebi_math.coordinates.normalized, komorebi_math.golden, komorebi_math.stable, komorebi_math.verify.generating. Examples (3): custom_generating_functions.py, mahler_cartier_compilers.py, prime_power_generating.py. Tests or test support files (6): test_block13_cli_api.py, test_block19_integration.py, test_generating_block13.py, test_generating_cartier_padic.py, test_generating_domains.py, and 1 more in the machine-readable ledger. Documentation files with literal module or public-route references (6): API_COMPATIBILITY_0.13.md, API_INVENTORY.md, BLOCK_13_RELEASE.md, GENERAL_COORDINATE_ATLAS.md, NORMALIZED_GENERATI

NG_FUNCTIONS.md, and 1 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.2 komorebi_math.generating.adapters

Purpose and source. Explicit bridges between formal generating functions and finite signals. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/adapters.py contains 155 lines and 5,553 bytes. Source SHA-256 begins 8a0a1f837ec254ad.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: fir_taps_to_series, FIRSeriesAdapter, series_to_fir_adapter, series_to_fir_taps. Its __all__ declaration contains 4 names: fir_taps_to_series, FIRSeriesAdapter, series_to_fir_adapter, series_to_fir_taps.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.generating.basis, komorebi_math.generating.series, komorebi_math.signals.filtering. Reverse package dependents (2): komorebi_math.generating, komorebi_math.verify.generating. Examples (0): none. Tests or test support files (1): test_generating_block13.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.3 komorebi_math.generating.basis

Purpose and source. Exact normalized monomial bases for formal generating functions. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/basis.py contains 448 lines and 15,462 bytes. Source SHA-256 begins 09829d076c6b799c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 23 manifest cards: 2 stable, 0 beta, and 21 research. Linked cards: factorial_power_basis, ordinary_generating_basis, factorial_power_basis, NormalizedBasis, ordinary_basis, WeightedMonomialBasis, exponential_basis, fibonacci_factorial_basis, NormalizedBasis, ordinary_basis, and 13 more in the machine-readable ledger. Its __all__ declaration contains 11 names: basis_from_descriptor, basis_from_values, BasisCertificate, BasisDescriptor, exponential_basis, factorial_power_basis, fibonacci_factorial_basis, ordinary_basis, pochhammer_basis, q_factorial_basis, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (15): komorebi_math, komorebi_math.coordinates.normalized, komorebi_math.generating, komorebi_math.generating.adapters, komorebi_math.generating.congruences, komorebi_math.generating.finite_series, and 9 more in the machine-readable ledger. Examples (1): custom_generating_functions.py. Tests or test support files (5): test_block19_integration.py, test_coordinates_normalized_persistence.py, test_generating_block13.py, test_generating_domains.py, test_generating_foundation.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.4 komorebi_math.generating.bell

Purpose and source. Factorial-power Bell recurrences and digit-sum compilers. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/bell.py contains 409 lines and 13,426 bytes. Source SHA-256 begins 4c5a85c09768939d.

Surface and ownership. API classification: API-manifested implementation owner. It owns 13 manifest cards: 0 stable, 0 beta, and 13 research. Linked cards: BellParityAutomaton, BellResidueAutomaton, generalized_bell_digit_reduction, bell_period_bound, BellDigitReduction, BellParityAutomaton, BellResidueAutomaton, certify_pointed_subindex_identity, generalized_bell_digit_reduction, generalized_bell_parity, and 3 more in the machine-readable ledger. Its __all__ declaration contains 10 names: bell_period_bound, BellDigitReduction, BellParityAutomaton, BellResidueAutomaton, certify_pointed_subindex_identity, generalized_bell_digit_reduction, generalized_bell_parity, pointed_subindex_polynomial, PointedSubindexCertificate, weighted_bell_digit_reduction.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptio

ns, komorebi_math.generating.budget, komorebi_math.generating.congruences, komorebi_math.generating.sequences. Reverse package dependents (4): komorebi_math, komorebi_math.cli.main, komorebi_math.generating, komorebi_math.verify.generating. Examples (1): prime_power_generating.py. Tests or test support files (2): test_block13_cli_api.py, test_generating_domains.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.5 komorebi_math.generating.budget

Purpose and source. Explicit resource contracts for generating-function compilation. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/budget.py contains 147 lines and 5,519 bytes. Source SHA-256 begins 10277f2d7fe126db.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: GeneratingBudget, DEFAULT_GENERATING_BUDGET, GeneratingBudget. Its __all__ declaration contains 2 names: DEFAULT_GENERATING_BUDGET, GeneratingBudget.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (7): komorebi_math, komorebi_math.generating, komorebi_math.generating.bell, komorebi_math.generating.cartier, komorebi_math.generating.finite_series, komorebi_math.generating.masks, and 1 more in the machine-readable ledger. Examples (0): none. Tests or test support files (3): test_block13_cli_api.py, test_generating_block13.py, test_generating_domains.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.6 komorebi_math.generating.cartier

Purpose and source. Cartier-section compilers for finite and rational Mahler masks. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/cartier.py contains 524 lines and 17,934 bytes. Source SHA-256 begins 73ec9bbb8ef2b8d7.

Surface and ownership. API classification: API-manifested implementation owner. It owns 15 manifest cards: 0 stable, 0 beta, and 15 research. Linked cards: compile_rational_mask_automaton, AutomatonCertificate, cartier_degree_bound, CartierAutomaton, CartierCarryEquivalence, CartierLinearRepresentation, certify_cartier_carry_equivalence, compile_cartier_linear_representation, compile_rational_mask_automaton, finite_mask_carry_matrices, and 5 more in the machine-readable ledger. Static analysis found 14 top-level public definitions: AutomatonCertificate, cartier_degree_bound, CartierAutomaton, CartierCarryEquivalence, CartierLinearRepresentation, certify_cartier_carry_equivalence, compile_cartier_linear_representation, compile_rational_mask_automaton, finite_mask_carry_matrices, minimize_cartier_automaton, and 4 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.exceptions, komorebi_math.generating.budget. Reverse package dependents (6): komorebi_math, komorebi_math.cli.main, komorebi_math.generating, komorebi_math.generating.masks, komorebi_math.generating.portable, komorebi_math.verify.generating. Examples (1): mahler_cartier_compilers.py. Tests or test support files (3): test_generating_block13.py, test_generating_cartier_padic.py, test_generating_domains.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.7 komorebi_math.generating.closed_forms

Purpose and source. Exact finite-prefix closed-form and recurrence recognition tools. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/closed_forms.py contains 482 lines and 17,781 bytes. Source SHA-256 begins 129b948581a0799a.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 0 stable, 0 beta, and 12 research. Linked cards: AlgebraicGFGuess, characteristic_closed_form, guess_algebraic_gf, guess_hypergeometric_ratio, guess_linear_recurrence, guess_p_recursive, guess_quasipolynomial, HypergeometricGuess, LinearRecurrenceGuess, PRecursiveGuess, and 2 more in the machine-readable ledger. Its __all__ declaration contains 12 names: AlgebraicGFGuess, characteristic_closed_form, guess_algebraic_gf, guess_hypergeometric_ratio, guess_linear_recurrence, guess_p_recursive, guess_quasipolynomial, HypergeometricGuess, LinearRecurrenceGuess, PRecursiveGuess, and 2 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.generating`. Examples (0): none. Tests or test support files (1): `test_generating_foundation.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.8 `komorebi_math.generating.congruences`

Purpose and source. Finite congruence discovery and exact verification tools. It is an ordinary module in the `generating` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/generating/congruences.py` contains 667 lines and 22,248 bytes. Source SHA-256 begins `db2e2d5a38d8ba6a`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 16 manifest cards: 0 stable, 0 beta, and 16 research. Linked cards: audit_apery_supercongruence, audit_factorial_power_packet_convolution, audit_generalized_bell_digit_sum, audit_generalized_lucas, audit_partition_lane, audit_q_lucas, audit_touchard, audit_weighted_generalized_bell_digit_sum, base_digit_sum, berlekamp_massey, and 6 more in the machine-readable ledger. Its `__all__` declaration contains 31 names: `audit_apery_supercongruence`, `audit_factorial_power_packet_convolution`, `audit_generalized_bell_digit_sum`, `audit_generalized_lucas`, `audit_partition_lane`, `audit_q_lucas`, `audit_touchard`, `audit_weighted_generalized_bell_digit_sum`, `base_digit_sum`, `berlekamp_massey`, and 21 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math.generating.basis`, `komorebi_math.generating.sequences`. Reverse package dependents (2): `komorebi_math.generating`, `komorebi_math.generating.bell`. Examples (0): none. Tests or test support files (1): `test_generating_foundation.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.9 `komorebi_math.generating.cyclotomic`

Purpose and source. Cyclotomic orbit tests for exact Mahler-product collapse. It is an ordinary module in the `generating` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/generating/cyclotomic.py` contains 163 lines and 5,335 bytes. Source SHA-256 begins `4410f5e15f14de2b`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: cyclotomic_coboundary, CyclotomicCollapse, normalized_cyclotomic_expression, p_free_orbit, verify_cyclotomic_coboundary, verify_cyclotomic_exponent_relation. Static analysis found 6 top-level public definitions: `cyclotomic_coboundary`, `CyclotomicCollapse`, `normalized_cyclotomic_expression`, `p_free_orbit`, `verify_cyclotomic_coboundary`, `verify_cyclotomic_exponent_relation`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.generating`. Examples (0): none. Tests or test support files (1): `test_generating_cartier_padic.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.10 `komorebi_math.generating.digit_algebra`

Purpose and source. Finite digit-kernel convolution laws for modular generating-function products. It is an ordinary module in the `generating` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/generating/digit_algebra.py` contains 245 lines and 8,549 bytes. Source SHA-256 begins `858b577e7a69049e`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: audit_factorial_power_digit_algebra, base_digits, DigitAlgebraAudit, DigitKernel, factorial_power_digit_kernel, lift_digit_sequence. Its `__all__` declaration contains 6 names: `audit_factorial_power_digit_algebra`, `base_digits`, `DigitAlgebraAudit`, `DigitKernel`, `factorial_power_digit_kernel`, `lift_digit_sequence`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (1): `komorebi_`

math.generating. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.11 komorebi_math.generating.domains

Purpose and source. Exact coefficient domains for normalized generating functions. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/domains.py contains 318 lines and 10,294 bytes. Source SHA-256 begins 225007918e1337aa.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: CoefficientDomain, domain_from_descriptor, INTEGER_DOMAIN, IntegerDomain, PrimeFieldDomain, RATIONAL_DOMAIN, RationalDomain, ResidueRingDomain, TruncatedPadicDomain. Its __all__ declaration contains 9 names: CoefficientDomain, domain_from_descriptor, INTEGER_DOMAIN, IntegerDomain, PrimeFieldDomain, RATIONAL_DOMAIN, RationalDomain, ResidueRingDomain, TruncatedPadicDomain.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (4): komorebi_math.generating, komorebi_math.generating.finite_series, komorebi_math.generating.portable, komorebi_math.verify.generating. Examples (1): custom_generating_functions.py. Tests or test support files (1): test_generating_domains.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.12 komorebi_math.generating.finite_series

Purpose and source. Immutable finite normalized series over explicit exact coefficient domains. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/finite_series.py contains 451 lines and 17,732 bytes. Source SHA-256 begins b31dab73da218f69.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: FiniteNormalizedSeries, FiniteNormalizedSeries, SeriesTransferCertificate. Its __all__ declaration contains 2 names: FiniteNormalizedSeries, SeriesTransferCertificate.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.generating.basis, komorebi_math.generating.budget, komorebi_math.generating.domains. Reverse package dependents (4): komorebi_math, komorebi_math.generating, komorebi_math.generating.portable, komorebi_math.verify.generating. Examples (1): custom_generating_functions.py. Tests or test support files (2): test_block13_cli_api.py, test_generating_domains.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.13 komorebi_math.generating.functions

Purpose and source. Declarative custom generating-function specifications for exact finite computation. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/functions.py contains 346 lines and 12,170 bytes. Source SHA-256 begins 3adfb83e7be377a3.

Surface and ownership. API classification: API-manifested implementation owner. It owns 13 manifest cards: 0 stable, 0 beta, and 13 research. Linked cards: CustomFunctionSpec, FunctionRegistry, algebraic_function, compose_functions, CustomFunctionSpec, euler_product_function, explicit_function, factorial_power_bell_function, FunctionRegistry, hypergeometric_function, and 3 more in the machine-readable ledger. Its __all__ declaration contains 11 names: algebraic_function, compose_functions, CustomFunctionSpec, euler_product_function, explicit_function, factorial_power_bell_function, FunctionRegistry, hypergeometric_function, linear_recurrence_function, rational_function, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.generating.basis, komorebi_math.generating.sequences, komorebi_math.generating.series. Reverse package dependents (3): komorebi_math, komorebi_math.generating, komorebi_math.generating.portable. Examples (1): custom_generating_functions.py. Tests or test support files (2): test_generating_block13.py, test_generating_foundation.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.14 komorebi_math.generating.masks

Purpose and source. Local Mahler masks, exact carry compilers, and prime-power support layers. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/masks.py contains 1,083 lines and 37,475 bytes. Source SHA-256 begins cd0f5beac88643f1.

Surface and ownership. API classification: API-manifested implementation owner. It owns 31 manifest cards: 0 stable, 0 beta, and 31 research. Linked cards: compile_finite_mask_carry_plan, FiniteMaskCarryPlan, mahler_mask_inverse, mahler_mask_product, analytic_mahler_product, AnalyticMaskApproximation, CarryLayerConvolution, certify_mahler_functional_equation, certify_rational_mask_algebraic_relation, compile_digit_cauchy_product, and 21 more in the machine-readable ledger. Its __all__ declaration contains 27 names: analytic_mahler_product, AnalyticMaskApproximation, CarryLayerConvolution, certify_mahler_functional_equation, certify_rational_mask_algebraic_relation, compile_digit_cauchy_product, compile_finite_mask_carry_plan, DigitCauchyProductPlan, euler_product_collapse, EulerProductCollapse, and 17 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.generating.budget, komorebi_math.generating.cartier, komorebi_math.generating.padic_units. Reverse package dependents (6): komorebi_math, komorebi_math.cli.main, komorebi_math.generating, komorebi_math.generating.portable, komorebi_math.golden, komorebi_math.verify.generating. Examples (1): mahler_cartier_compilers.py. Tests or test support files (1): test_generating_block13.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.15 komorebi_math.generating.monoid

Purpose and source. Finite additive and multiplicative monoid series. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/monoid.py contains 102 lines and 3,811 bytes. Source SHA-256 begins 6912891418926c36.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: additive_series, dirichlet_convolution, FiniteMonoidSeries, multiplicative_series, prime_valuation_packets. Its __all__ declaration contains 5 names: additive_series, dirichlet_convolution, FiniteMonoidSeries, multiplicative_series, prime_valuation_packets.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (1): komorebi_math.generating. Examples (0): none. Tests or test support files (1): test_generating_foundation.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.16 komorebi_math.generating.normalization

Purpose and source. Carry-linear valuation profiles and digit-local unit twists. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/normalization.py contains 194 lines and 6,413 bytes. Source SHA-256 begins c862b1945b622a1a.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: CarryLinearCertificate, CarryLinearValuation, classify_carry_linear_valuation, digit_factorized_normalized_kernel, digit_unit, local_normalized_kernel. Static analysis found 7 top-level public definitions: base_digits, CarryLinearCertificate, CarryLinearValuation, classify_carry_linear_valuation, digit_factorized_normalized_kernel, digit_unit, local_normalized_kernel.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.exceptions, komorebi_math.generating.padic_units. Reverse package dependents (1): komorebi_math.generating. Examples (0): none. Tests or test support files (1): test_generating_cartier_padic.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.17 komorebi_math.generating.padic_units

Purpose and source. Exact prime-power unit-factorial and custom kernel compilers. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/padic_units.py contains 301 lines and 9,487 bytes. Source SHA-256 begins 3c4e77f1eb3a55f6.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: PrimePowerKernelCompiler, binomial_valuation, borrow_count, factorial_valuation, integer_valuation, NormalizedKernelResidue, PrimePowerBinomial, PrimePowerKernelCompiler, PrimePowerUnitCompiler. Static analysis found 9 top-level public definitions: binomial_valuation, borrow_count, constant_unit_sequence, factorial_valuation, integer_valuation, NormalizedKernelResidue, PrimePowerBinomial, PrimePowerKernelCompiler, PrimePowerUnitCompiler.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (8): komorebi_math, komorebi_math.cli.main, komorebi_math.generating, komorebi_math.generating.masks, komorebi_math.generating.normalization, komorebi_math.generating.q_kummer, and 2 more in the machine-readable ledger. Examples (1): prime_power_generating.py. Tests or test support files (2): test_generating_block13.py, test_generating_cartier_padic.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.18 komorebi_math.generating.portable

Purpose and source. Trusted finite snapshots and portable codecs for generating-function objects. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/portable.py contains 495 lines and 18,857 bytes. Source SHA-256 begins 6a6fdf84655de482.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: freeze_custom_function, FrozenGeneratingFunction, freeze_custom_function, FrozenGeneratingFunction, register_generating_codecs. Its __all__ declaration contains 3 names: freeze_custom_function, FrozenGeneratingFunction, register_generating_codecs.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (10): komorebi_math.exceptions, komorebi_math.export.persistence, komorebi_math.generating.basis, komorebi_math.generating.budget, komorebi_math.generating.cartier, komorebi_math.generating.domains, and 4 more in the machine-readable ledger. Reverse package dependents (3): komorebi_math, komorebi_math.export.persistence, komorebi_math.generating. Examples (1): custom_generating_functions.py. Tests or test support files (1): test_generating_block13.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.19 komorebi_math.generating.q_kummer

Purpose and source. Mixed-radix Kummer formulas for integer Gaussian binomial coefficients. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/q_kummer.py contains 212 lines and 6,258 bytes. Source SHA-256 begins 6160a345c7538e85.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: q_binomial_valuation_decomposition, gaussian_binomial, multiplicative_order_mod_prime, q_binomial_support, q_binomial_valuation_decomposition, q_binomial_valuation_direct, q_factorial, q_integer, QKummerDecomposition. Static analysis found 8 top-level public definitions: gaussian_binomial, multiplicative_order_mod_prime, q_binomial_support, q_binomial_valuation_decomposition, q_binomial_valuation_direct, q_factorial, q_integer, QKummerDecomposition.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.generating.padic_units. Reverse package dependents (3): komorebi_math, komorebi_math.generating, komorebi_math.verify.generating. Examples (1): prime_power_generating.py. Tests or test support files (1): test_generating_cartier_padic.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.20 komorebi_math.generating.sections

Purpose and source. Universal custom exponential sections under the basis lowering operator. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/sections.py contains 123 lines and 3,590 bytes. Source SHA-256 begins 4b8f10c0f695fa95.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: audit_section_cycle, custom_exponential, custom_section, root_filter_value, SectionCycleAudit. Its __all__ declaration contains 5 names: audit_section_cycle, custom_exponential, custom_section, root_filter_value, SectionCycleAudit.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.generating.basis, komorebi_math.generating.series. Reverse package dependents (1): komorebi_math.generating. Examples (0): none. Tests or test support files (1): test_generating_foundation.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.21 komorebi_math.generating.sequences

Purpose and source. Exact benchmark and custom sequence families. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/sequences.py contains 268 lines and 8,468 bytes. Source SHA-256 begins f7865546be191e8e.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 0 stable, 0 beta, and 12 research. Linked cards: apery_numbers, bell_numbers, bernoulli_numbers, catalan_numbers, central_binomial_numbers, fibonacci_numbers, generalized_bell_numbers, generalized_bell_polynomials, partition_numbers, signed_euler_numbers, and 2 more in the machine-readable ledger. Its __all__ declaration contains 14 names: apery_numbers, bell_numbers, bernoulli_numbers, catalan_numbers, central_binomial_numbers, fibonacci_numbers, finite_differences, generalized_bell_hypergeometric_inner, generalized_bell_numbers, generalized_bell_polynomials, and 4 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (5): komorebi_math.generating, komorebi_math.generating.bell, komorebi_math.generating.congruences, komorebi_math.generating.functions, komorebi_math.verify.generating. Examples (0): none. Tests or test support files (2): test_generating_domains.py, test_generating_foundation.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.12.22 komorebi_math.generating.series

Purpose and source. Exact truncated formal-series operations in a custom normalized basis. It is an ordinary module in the generating family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/generating/series.py contains 324 lines and 13,500 bytes. Source SHA-256 begins e53da8fbe75432cf.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 1 stable, 0 beta, and 3 research. Linked cards: FormalSeries, FormalSeries, FormalSeries, PacketIdentity. Its __all__ declaration contains 2 names: FormalSeries, PacketIdentity.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.generating.basis. Reverse package dependents (11): komorebi_math, komorebi_math.generating, komorebi_math.generating.adapters, komorebi_math.generating.functions, komorebi_math.generating.portable, komorebi_math.generating.sections, and 5 more in the machine-readable ledger. Examples (0): none. Tests or test support files (3): test_block19_integration.py, test_generating_block13.py, test_generating_foundation.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13 Signals: 21 modules

D.2.13.1 komorebi_math.signals

Purpose and source. Executable multiresolution signal calculus and singular packet tools. It is the package initializer for the signals family. The ledger classifies it as a canonical API namespace facade and owner. Source src/komorebi_math/signals/__init__.py contains 379 lines and 9,229 bytes. Source SHA-256 begins 6f57c41ee2ae91f3.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: status. Its __all__ declaration contains 171 names: AdaptiveFilterResult, AdaptiveMethod, best_basis, BestBasisResult, BiquadKind, BoundaryMode, BreakpointBandResult, canonical_dual_window, certified_overlap_add_convolve, coefficient_packets, and 161 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (22): komorebi_math._planned, komorebi_math.registry, komorebi_math.signals.adaptive, komorebi_math.signals.approximation, komorebi_math.signals.convolution, komorebi_math.signals.denoise, and 16 more in the machine-readable ledger. Reverse package dependents (5): komorebi_math, komorebi_math.qualification, komorebi_math.verify.dsp, komorebi_math.verify.signals, komorebi_math.verify.stabilization. Examples (5): block15_polyphase_refinement.py, block21_public_capability_tour.py, polyphase_filterbank.py, production_dsp.py, singular_packet_recovery.py. Tests or test support files (13): test_block12_cli_api.py, test_block12_denoise_streaming.py, test_block12_recursive_fft.py, test_block12_resampling_adaptive.py, test_block12_spectral_filtering.py, and 8 more in the machine-readable ledger. Documentation files with literal module or public-route references (8): API_COMPATIBILITY_0.12.md, API_COMPATIBILITY_0.13.md, API_INVENTORY.md, BLOCK_12_RELEASE.md, BLOCK_4_RELEASE.md, and 3 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.2 komorebi_math.signals.adaptive

Purpose and source. Finite LMS, normalized LMS, and recursive least-squares adaptation. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/adaptive.py contains 313 lines and 11,711 bytes. Source SHA-256 begins 2266adb261be7ece.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: AdaptiveFilterResult, lms_filter, nlms_filter, rls_filter. Its __all__ declaration contains 5 names: AdaptiveFilterResult, AdaptiveMethod, lms_filter, nlms_filter, rls_filter.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_resampling_adaptive.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.3 komorebi_math.signals.approximation

Purpose and source. Fourier approximation and deliberately narrow packet estimators. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/approximation.py contains 121 lines and 4,692 bytes. Source SHA-256 begins 639eb8b4061599fb.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: estimate_positive_packet_1d, fft_lowpass_1d, fft_lowpass_2d, otsu_threshold, PacketEstimate1D. Its __all__ declaration contains 5 names: estimate_positive_packet_1d, fft_lowpass_1d, fft_lowpass_2d, otsu_threshold, PacketEstimate1D.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.signals. Examples (0): none. Tests or test support files (1): test_signals_extended.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.4 komorebi_math.signals.convolution

Purpose and source. Finite convolution operators and their exact polyphase blocks. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/convolution.py contains 257 lines and 8,846 bytes. Source SHA-256 begins 2260b1f8345213ad.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: convolution_matrix, convolution_output_length, convolve_signal, finite_polyphase_blocks, finite_polyphase_filter_kernels, FinitePolyphaseKernel, polyphase_convolution, PolyphaseBlockMatrix, PolyphaseConvolution. Its __all__ declaration contains 8 names: convolution_matrix, convolution_output_length, ConvolutionMode, convolve_signal, finite_polyphase_blocks, polyphase_convolution, PolyphaseBlockMatrix, PolyphaseConvolution.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.polyphase. Reverse package dependents (3): komorebi_math.signals, komorebi_math.signals.filterbanks, komorebi_math.signals.polyphase. Examples (1): polyphase_filterbank.py. Tests or test support files (2): test_block4_hardening.py, test_signals_polyphase_filterbanks.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.5 komorebi_math.signals.denoise

Purpose and source. Finite Haar shrinkage and threshold selection for deterministic denoising. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/denoise.py contains 373 lines and 15,173 bytes. Source SHA-256 begins f949f18afa533173.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 0 stable, 0 beta, and 10 research. Linked cards: denoising_risk_certificate, estimate_white_noise_sigma, haar_decompose, HaarDecomposition, median_absolute_deviation, sure_threshold, threshold_coefficients, universal_threshold, wavelet_denoise, WaveletDenoiseResult. Its __all__ declaration contains 12 names: denoising_risk_certificate, estimate_white_noise_sigma, haar_decompose, HaarDecomposition, median_absolute_deviation, sure_threshold, threshold_coefficients, ThresholdMode, ThresholdRule, universal_threshold, and 2 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.filterbanks. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_denoise_streaming.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.6 komorebi_math.signals.edge_recovery

Purpose and source. Certified recovery of separated jumps from finite samples. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/edge_recovery.py contains 273 lines and 10,275 bytes. Source SHA-256 begins a0d9a34fa46230b7.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: half_shift_distance, recover_vector_jumps, recover_vector_jumps_subgaussian, smooth_haar_coefficient_bound, step_haar_coefficient, VectorJumpRecoveryResult. Its __all__ declaration contains 6 names: half_shift_distance, JumpRecoveryResult, recover_jumps, recover_jumps_subgaussian, smooth_haar_coefficient_bound, step_haar_coefficient.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.singular_packets. Reverse package dependents (1): komorebi_math.signals. Examples (0): none. Tests or test support files (1): test_block4_hardening.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.7 komorebi_math.signals.fft_convolution

Purpose and source. FFT convolution and bounded-buffer overlap-add execution. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/fft_convolution.py contains 253 lines and 10,317 bytes. Source SHA-256 begins 3f88cfd9bd289139.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: certified_overlap_add_convolve, fft_convolve, overlap_add_convolve, OverlapAddConvolver. Its __all__ declaration contains 4 names: certified_overlap_add_convolve, fft_convolve, overlap_add_convolve, OverlapAddConvolver.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.filtering. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_recursive_fft.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.8 komorebi_math.signals.filterbanks

Purpose and source. Finite periodic filter banks, frames, and lifting schemes. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/filterbanks.py contains 444 lines and 18,907 bytes. Source SHA-256 begins 41c241aeaf678fd2.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 0 stable, 0 beta, and 12 research. Linked cards: PeriodicFilterBank, FilterBankReport, FiniteFilterBank, haar_analyze, haar_filter_bank, haar_matrix, haar_synthesize, HaarFilterBank, periodic_five_three_lifting, PeriodicFilterBank, and 2 more in the machine-readable ledger. Its __all__ declaration contains 11 names: FilterBankReport, FiniteFilterBank, haar_analyze, haar_filter_bank, haar_matrix, haar_synthesize, HaarFilterBank, periodic_five_three_lifting, PeriodicFilterBank, PeriodicLiftingScheme, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.convolution. Reverse package dependents (5): komorebi_math, komorebi_math.signals, komorebi_math.signals.denoise, komorebi_math.signals.wavelets, komorebi_math.verify.signals. Examples (1): polyphase_filterbank.py. Tests or test support files (2): test_signals_extended.py, test_signals_polyphase_filterbanks.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.9 komorebi_math.signals.filtering

Purpose and source. Finite FIR design, direct filtering, and stateful streaming execution. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/filtering.py contains 451 lines and 16,677 bytes. Source SHA-256 begins f694446c17d6f8ff.

Surface and ownership. API classification: API-manifested implementation owner. It owns 11 manifest cards: 0 stable, 0 beta, and 11 research. Linked cards: design_bandpass, design_bandstop, design_fir, design_highpass, design_lowpass, fir_filter, fir_frequency_response, FIRFilter, FrequencyResponse, stream_fir_filter, and 1 more in the machine-readable ledger. Its __all__ declaration contains 13 names: design_bandpass, design_bandstop, design_fir, design_highpass, design_lowpass, fir_filter, fir_frequency_response, FIRFilter, FIRKind, FIRMode, and 3 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.windows. Reverse package dependents (5): komorebi_math.generating.adapters, komorebi_math.signals, komorebi_math.signals.fft_convolution, komorebi_math.signals.recursive, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (2): test_block12_resampling_adaptive.py, test_block12_spectral_filtering.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.10 komorebi_math.signals.nonlinear

Purpose and source. Nonlinear residue packet identities for finite signal sequences. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/nonlinear.py contains 186 lines and 8,235 bytes. Source SHA-256 begins 711b02775de75032.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: coefficient_packets, nonlinear_shift_filter, packet_product. Its __all__ declaration contains 3 names: coefficient_packets, nonlinear_shift_filter, packet_product.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.signals. Examples (0): none. Tests or test support files (2): test_block4_hardening.py, test_signals_extended.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.11 komorebi_math.signals.polyphase

Purpose and source. Finite polyphase coordinates, residue projectors, and transfer kernels. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/polyphase.py contains 485 lines and 19,299 bytes. Source SHA-256 begins bcfda9ec1c68b4cc.

Surface and ownership. API classification: API-manifested implementation owner. It owns 26 manifest cards: 10 stable, 0 beta, and 16 research. Linked cards: lattice_polyphase_analyze, lattice_polyphase_synthesize, LatticePolyphaseCoordinates, polyphase_roundtrip_certificate, PolyphaseCoordinates, PolyphaseSystem, refinement_children, residue_project, signal_polyphase_analyze, signal_polyphase_synthesize, and 16 more in the machine-readable ledger. Its __all__ declaration contains 15 names: lattice_polyphase_analyze, lattice_polyphase_synthesize, LatticePolyphaseCoordinates, mixed_radix_address, polyphase_analyze, polyphase_convolution, polyphase_filter_kernels, polyphase_roundtrip_certificate, polyphase_synthesize, PolyphaseCoordinates, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.refinement.polyphase, komorebi_math.signals.convolution. Reverse package dependents (10): komorebi_math, komorebi_math.qualification, komorebi_math.refinement.polyphase, komorebi_math.refinement.portable, komorebi_math.signals, komorebi_math.signals.convolution, and 4 more in the machine-readable ledger. Examples (3): block15_polyphase_refinement.py, block21_public_capability_tour.py, polyphase_filterbank.py. Tests or test support files (5): test_block15_persistence.py, test_block15_polyphase_refinement.py, test_block4_hardening.py, test_signals_extended.py, test_signals_polyphase_filterbanks.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.12 komorebi_math.signals.recovery

Purpose and source. Stable recovery of separated jumps and piecewise polynomial breakpoints. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/recovery.py contains 301 lines and 11,712 bytes. Source SHA-256 begins be8e22ea519e686a.

Surface and ownership. API classification: API-manifested implementation owner. It owns 11 manifest cards: 0 stable, 0 beta, and 11 research. Linked cards: recover_separated_jumps, BreakpointBandResult, detect_piecewise_polynomial_breaks, finite_difference, haar_lipschitz_bound, haar_step_coefficient, JumpDetection, JumpRecoveryResult, recover_jumps_subgaussian, recover_separated_jumps, and 1 more in the machine-readable ledger. Its __all__ declaration contains 10 names: BreakpointBandResult, detect_piecewise_polynomial_breaks, finite_difference, haar_lipschitz_bound, haar_step_coefficient, JumpDetection, JumpRecoveryResult, recover_jumps_subgaussian, recover_separated_jumps, subgaussian_noise_bound.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math, komorebi_math.signals, komorebi_math.verify.signals. Examples (1): singular_packet_recovery.py. Tests or test support files (1): test_signals_recovery.py. Documentation files with literal module or

public-route references (1): PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.13 komorebi_math.signals.recursive

Purpose and source. Finite recursive digital filters, biquad design, and chunked state transport. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/recursive.py contains 312 lines and 11,845 bytes. Source SHA-256 begins 1282eca34e17ca83.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: design_biquad, FilterOutput, lfilter, LinearFilter, stream_lfilter, StreamingLinearFilter. Its __all__ declaration contains 7 names: BiquadKind, design_biquad, FilterOutput, lfilter, LinearFilter, stream_lfilter, StreamingLinearFilter.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.filtering. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_recursive_fft.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.14 komorebi_math.signals.resampling

Purpose and source. Finite rational resampling with explicit polyphase execution. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/resampling.py contains 305 lines and 11,036 bytes. Source SHA-256 begins 051a0a75295f6df6.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 0 stable, 0 beta, and 10 research. Linked cards: decimate, design_resample_filter, downsample, interpolate, RationalResamplingPlan, resample_poly, resample_poly_result, resampled_length, ResamplingResult, upsample. Its __all__ declaration contains 10 names: decimate, design_resample_filter, downsample, interpolate, RationalResamplingPlan, resample_poly, resample_poly_result, resampled_length, ResamplingResult, upsample.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.windows. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_resampling_adaptive.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.15 komorebi_math.signals.singular_packets

Purpose and source. One dimensional singular packets and exact reconstruction identities. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/singular_packets.py contains 531 lines and 20,253 bytes. Source SHA-256 begins 856d0f0739890bcb.

Surface and ownership. API classification: API-manifested implementation owner. It owns 16 manifest cards: 0 stable, 0 beta, and 16 research. Linked cards: retained_packet_reconstruct, SingularPacket1D, difference_noise_bound, estimated_packet_reconstruct, overlap_matrix_error, overlap_partition_lp_error, retained_packet_reconstruct, retained_packet_reconstruction, RetainedPacketReconstruction, RetainedPacketResult, and 6 more in the machine-readable ledger. Its __all__ declaration contains 15 names: difference_noise_bound, estimated_packet_reconstruct, finite_difference, overlap_matrix_error, overlap_partition_lp_error, retained_packet_reconstruct, retained_packet_reconstruction, RetainedPacketReconstruction, RetainedPacketResult, scalar_region_error, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (4): komorebi_math, komorebi_math.signals, komorebi_math.signals.edge_recovery, komorebi_math.verify.signals. Examples (1): singular_packet_recovery.py. Tests or test support files (3): test_block4_hardening.py, test_signals_

extended.py, test_signals_wavelets_singular.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.16 komorebi_math.signals.smith

Purpose and source. Cyclic Cayley coordinates used as a secondary signal realization. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/smith.py contains 55 lines and 2,190 bytes. Source SHA-256 begins 2590d54d968ad654.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: gamma_from_impedance, impedance_from_gamma, phase_mobius, smith_sensitivity. Its __all__ declaration contains 4 names: gamma_from_impedance, impedance_from_gamma, phase_mobius, smith_sensitivity.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.signals. Examples (0): none. Tests or test support files (1): test_signals_extended.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.17 komorebi_math.signals.spectral

Purpose and source. Finite Fourier spectra, Welch estimates, cross spectra, and coherence. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/spectral.py contains 438 lines and 17,134 bytes. Source SHA-256 begins 3368f345b9aaa55e.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: cross_spectrum, CrossSpectrum, parseval_certificate, periodogram, PowerSpectrum, welch_psd. Its __all__ declaration contains 8 names: cross_spectrum, CrossSpectrum, parseval_certificate, periodogram, PowerSpectrum, SpectralAverage, SpectralScaling, welch_psd.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.time_frequency, komorebi_math.signals.windows. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_spectral_filtering.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.18 komorebi_math.signals.streaming

Purpose and source. Stateful chunked short-time Fourier analysis with batch equivalence certificates. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/streaming.py contains 346 lines and 13,441 bytes. Source SHA-256 begins 906f29ed7a2828ee.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: stream_stft, StreamingSTFT, StreamingSTFTBatch. Its __all__ declaration contains 3 names: stream_stft, StreamingSTFT, StreamingSTFTBatch.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.time_frequency, komorebi_math.signals.windows. Reverse package dependents (2): komorebi_math.signals, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_denoise_streaming.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.19 komorebi_math.signals.time_frequency

Purpose and source. Finite framing, short-time Fourier transforms, and overlap-add synthesis. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/time_frequency.py contains 493 lines and 18,516 bytes. Source SHA-256 begins e127fadcb3d83e9c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 0 stable, 0 beta, and 8 research. Linked cards: frame_signal, FrameBatch, istft, overlap_add, spectrogram, SpectrogramResult, stft, STFTResult. Its __all__ declaration contains 11 names: BoundaryMode, DetrendMode, frame_signal, FrameBatch, istft, overlap_add, spectrogram, SpectrogramResult, SpectrogramScaling, stft, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.windows. Reverse package dependents (4): komorebi_math.signals, komorebi_math.signals.spectral, komorebi_math.signals.streaming, komorebi_math.verify.dsp. Examples (1): production_dsp.py. Tests or test support files (1): test_block12_windows_time_frequency.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.20 komorebi_math.signals.wavelets

Purpose and source. Finite Haar packet trees, admissible prunings, and exact best bases. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/wavelets.py contains 387 lines and 14,348 bytes. Source SHA-256 begins 418c10491f59da24.

Surface and ownership. API classification: API-manifested implementation owner. It owns 11 manifest cards: 0 stable, 0 beta, and 11 research. Linked cards: HaarPacketTree, best_basis, BestBasisResult, entropy_cost, haar_packet_analyze, haar_packet_synthesize, HaarPacketTree, lp_cost, packet_energy, PrunedPacketCoefficients, and 1 more in the machine-readable ledger. Its __all__ declaration contains 12 names: best_basis, BestBasisResult, CostFunction, entropy_cost, haar_packet_analyze, haar_packet_synthesize, HaarPacketTree, lp_cost, packet_energy, PacketPath, and 2 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.signals.filterbanks. Reverse package dependents (3): komorebi_math, komorebi_math.signals, komorebi_math.verify.signals. Examples (1): polyphase_filterbank.py. Tests or test support files (1): test_signals_wavelets_singular.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.13.21 komorebi_math.signals.windows

Purpose and source. Deterministic finite windows and overlap-add diagnostics. It is an ordinary module in the signals family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/signals/windows.py contains 317 lines and 11,919 bytes. Source SHA-256 begins fa18b3d5c0aa1747.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: canonical_dual_window, get_window, overlap_add_certificate, overlap_profile, window_metrics, WindowMetrics. Its __all__ declaration contains 8 names: canonical_dual_window, get_window, overlap_add_certificate, overlap_profile, window_metrics, WindowMetrics, WindowName, WindowSpec.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (7): komorebi_math.signals, komorebi_math.signals.filtering, komorebi_math.signals.resampling, komorebi_math.signals.spectral, komorebi_math.signals.streaming, komorebi_math.signals.time_frequency, and 1 more in the machine-readable ledger. Examples (0): none. Tests or test support files (1): test_block12_windows_time_frequency.py. Documentation files with literal module or public-route references (1): BLOCK_12_RELEASE.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.14 Nonlinear: 22 modules

D.2.14.1 komorebi_math.nonlinear

Purpose and source. Finite nonlinear packet calculus, obstruction theory, and smooth transport. It is the package initializer for the nonlinear family. The ledger classifies it as a canonical API namespace facade and owner. Source src/komorebi_math/nonlinear/__init__.py contains 347 lines and 9,344 bytes. Source SHA-256 begins 2d8d2b30 b1dace1f.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: require, status. Its __all__ declaration contains 149 names: autodiff_provider, automatic_derivative_provider, AutomaticDifferentiationProvider, available_ad_frameworks, available_autodiff_backends, build_lift_tree, CallableDerivativeProvider, capture_packet_jet_stream, catalan_number, compile_packet_jet_plan, and 139 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (22): komorebi_math.nonlinear.autodiff, komorebi_math.nonlinear.composition, komorebi_math.nonlinear.coordinates, komorebi_math.nonlinear.correction, komorebi_math.nonlinear.defects, komorebi_math.nonlinear.derivatives, and 16 more in the machine-readable ledger. Reverse package dependents (7): komorebi_math, komorebi_math.cli.main, komorebi_math.langlands.local.bridge, komorebi_math.verify.nonlinear, komorebi_math.verify.nonlinear_advanced, komorebi_math.verify.scalable_nonlinear, and 1 more in the machine-readable ledger. Examples (9): block11_semantic_profile.py, filtered_transport.py, nonlinear_jets_composition.py, nonlinear_trees_elimination.py, obstruction_lifting.py, and 4 more in the machine-readable ledger. Tests or test support files (20): optional_backend_support.py, test_block10_execution_persistence.py, test_block10_sparse_autodiff.py, test_block11_cli.py, test_block11_golden_profiling_beta.py, and 15 more in the machine-readable ledger. Documentation files with literal module or public-route references (11): API_COMPATIBILITY_0.11.md, API_COMPATIBILITY_0.12.md, API_COMPATIBILITY_0.13.md, API_INVENTORY.md, API_STABILITY_REVIEW.md, and 6 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.2 komorebi_math.nonlinear.autodiff

Purpose and source. Optional automatic-differentiation adapters for directional derivatives. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/autodiff.py contains 728 lines and 26,563 bytes. Source SHA-256 begins dae6aa596e657ae5.

Surface and ownership. API classification: API-manifested implementation owner. It owns 16 manifest cards: 0 stable, 0 beta, and 16 research. Linked cards: autodiff_provider, automatic_derivative_provider, AutomaticDifferentiationProvider, available_ad_frameworks, available_autodiff_backends, DirectionalJVP, JaxDerivativeProvider, TorchDerivativeProvider, autodiff_provider, automatic_derivative_provider, and 6 more in the machine-readable ledger. Its __all__ declaration contains 9 names: ad_framework_diagnostics, autodiff_provider, automatic_derivative_provider, AutomaticDifferentiationProvider, available_ad_frameworks, available_autodiff_backends, DirectionalJVP, JaxDerivativeProvider, TorchDerivativeProvider.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (5): komorebi_math, komorebi_math.nonlinear, komorebi_math.qualification, komorebi_math.support, komorebi_math.verify.scalable_nonlinear. Examples (0): none. Tests or test support files (4): optional_backend_support.py, test_block10_sparse_autodiff.py, test_nonlinear_sparse_autodiff.py, test_optional_backend_probe.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.3 komorebi_math.nonlinear.composition

Purpose and source. Higher chain rules and packet Faà di Bruno composition. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/composition.py contains 447 lines and 18,130 bytes. Source SHA-256 begins 56bf1bc5b8f5a2b6.

Surface and ownership. API classification: API-manifested implementation owner. It owns 11 manifest cards: 0 stable, 0 beta, and 11 research. Linked cards: ComposedDerivativeProvider, faa_di_bruno, packet_faa_di_bruno, ComposedDerivativeProvider, faa_di_bruno, FaaDiBrunoResult, FaaDiBrunoTerm, labeled_composition_term_count, packet_faa_di_bruno, set_partitions, and 1 more in the machine-readable ledger. Its __all__ declaration contains 9 names: ComposedDerivativeProvider, faa_di_bruno, FaaDiBrunoResult, FaaDiBrunoTerm, labeled_composition_term_count, packet_faa_di_bruno, Partition, set_partitions, stirling_second.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): komorebi_math.certificates, komorebi_math.core.packets, komorebi_math.exceptions, komorebi_math.nonlinear.derivatives, komorebi_math.nonlinear.jets, komorebi_math.provenance. Reverse package dependents (3): komorebi_math, komorebi_math.nonlinear, komorebi_math.verify.nonlinear_advanced. Examples (1): nonlinear_jets_composition.py. Tests or test support files (1): test_nonlinear_jets_composition.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.4 komorebi_math.nonlinear.coordinates

Purpose and source. Exact coordinate conjugation for nonlinear maps. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/coordinates.py contains 110 lines and 5,073 bytes. Source SHA-256 begins b99aba8af7fd53d3.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: NonlinearPacketMap, NonlinearPacketMap. Its __all__ declaration contains 1 name: NonlinearPacketMap.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.core.packets, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math, komorebi_math.nonlinear, komorebi_math.verify.nonlinear. Examples (0): none. Tests or test support files (1): test_nonlinear_coordinates_defects.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.5 komorebi_math.nonlinear.correction

Purpose and source. Quantitative nonlinear correction and finite Lyapunov-Schmidt reduction. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/correction.py contains 538 lines and 24,456 bytes. Source SHA-256 begins 6ae92fabdd5d87fc.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 0 stable, 0 beta, and 10 research. Linked cards: HilbertObstructionProjector, LyapunovSchmidtReduction, RightInverseCorrectionProblem, HilbertObstructionProjector, HilbertObstructionResult, LyapunovSchmidtDecomposition, LyapunovSchmidtPoint, LyapunovSchmidtReduction, RightInverseCorrectionProblem, RightInverseCorrectionResult. Its __all__ declaration contains 7 names: HilbertObstructionProjector, HilbertObstructionResult, LyapunovSchmidtDecomposition, LyapunovSchmidtPoint, LyapunovSchmidtReduction, RightInverseCorrectionProblem, RightInverseCorrectionResult.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.nonlinear.derivatives, komorebi_math.provenance. Reverse package dependents (3): komorebi_math, komorebi_math.nonlinear, komorebi_math.verify.nonlinear_advanced. Examples (1): nonlinear_trees_elimination.py. Tests or test support files (1): test_nonlinear_correction_elimination.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.6 komorebi_math.nonlinear.defects

Purpose and source. Nonlinear refinement defects and stability bounds. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/defects.py contains 131 lines and 5,032 bytes. Source SHA-256 begins c035ec4f6ea1dcee.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: NonlinearRefinementDefect, NonlinearRefinementDefect. Its __all__ declaration contains 1 name: NonlinearRefinementDefect.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (3): komorebi_math, komorebi_math.nonlinear, komorebi_math.verify.nonlinear. Examples (0): none. Tests or test support files (1): test_nonlinear_coordinates_defects.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.7 komorebi_math.nonlinear.derivatives

Purpose and source. Finite-dimensional derivative providers for nonlinear packet calculus. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/derivatives.py contains 549 lines and 24,044 bytes. Source SHA-256 begins 2d2084098d5a2cb3.

Surface and ownership. API classification: API-manifested implementation owner. It owns 13 manifest cards: 0 stable, 4 beta, and 9 research. Linked cards: CallableDerivativeProvider, DerivativeProvider, FiniteDifferenceDerivativeProvider, PolynomialDerivativeProvider, CallableDerivativeProvider, FiniteDifferenceDerivativeProvider, PolynomialDerivativeProvider, SympyDerivativeProvider, CallableDerivativeProvider, DerivativeProvider, and 3 more in the machine-readable ledger. Its __all__ declaration contains 6 names: CallableDerivativeProvider, DerivativeProvider, DirectionalDerivative, FiniteDifferenceDerivativeProvider, PolynomialDerivativeProvider, SympyDerivativeProvider.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (13): komorebi_math, komorebi_math.beta, komorebi_math.golden, komorebi_math.nonlinear, komorebi_math.nonlinear.composition, komorebi_math.nonlinear.correction, and 7 more in the machine-readable ledger. Examples (7): block11_semantic_profile.py, nonlinear_jets_composition.py, nonlinear_trees_elimination.py, portable_nonlinear_state.py, resumable_packet_jet_stream.py, and 2 more in the machine-readable ledger. Tests or test support files (10): test_block10_execution_persistence.py, test_block11_cli.py, test_block11_golden_profiling_beta.py, test_block11_streaming_migrations.py, test_nonlinear_correction_elimination.py, and 5 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.8 komorebi_math.nonlinear.elimination

Purpose and source. Finite nonlinear Schur elimination through second order. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/elimination.py contains 496 lines and 20,155 bytes. Source SHA-256 begins eb257c3e02a55333.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: NonlinearSchurElimination, HiddenSolveResult, NonlinearSchurElimination, SchurDerivativeResult, SchurSecondDerivativeResult. Its __all__ declaration contains 4 names: HiddenSolveResult, NonlinearSchurElimination, SchurDerivativeResult, SchurSecondDerivativeResult.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.nonlinear.derivatives, komorebi_math.provenance. Reverse package dependents (3): komorebi_math, komorebi_math.nonlinear, komorebi_math.verify.nonlinear_advanced. Examples (1): nonlinear_trees_elimination.py. Tests or test support files (1): test_nonlinear_correction_elimination.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.9 komorebi_math.nonlinear.execution

Purpose and source. Projection-cached packet-jet execution and optional CuPy kernels. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/execution.py contains 696 lines and 27,704 bytes. Source SHA-256 begins 474902031dcfa406.

Surface and ownership. API classification: API-manifested implementation owner. It owns 29 manifest cards: 0 stable, 7 beta, and 22 research. Linked cards: compile_packet_jet_plan, execute_packet_jet_plan, execute_packet_jets, PacketJetBatchResult, PacketJetEvaluation, PacketJetExecutionPlan, PacketJetInputGroup, compile_packet_jet_plan, CuPyDeviceDerivativeProvider, CuPyPacketJetExecutor, and 19 more in the machine-readable ledger. Its __all__ declaration contains 15 names: compile_packet_jet_plan, CuPyDeviceDerivativeProvider, CupyDeviceDerivativeProvider, CupyPacketJetExecutor, CuPyPacketJetExecutor, CuPyPolynomialDerivativeProvider, CupyPolynomialDerivativeProvider, execute_packet_jet_plan, execute_packet_jets, nonlinear_cupy_available, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: optional CuPy accelerator outside the declared project extras, required NumPy dependency. Direct package dependencies (6): komorebi_math.algorithms.benchmarks, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.nonlinear.derivatives, komorebi_math.nonlinear.jets, komorebi_math.provenance. Reverse package dependents (6): komorebi_math, komorebi_math.beta, komorebi_math.golden, komorebi_math.nonlinear, komorebi_math.nonlinear.profiling, komorebi_math.verify.scalable_nonlinear. Examples (2): scalable_nonlinear.py, scalable_nonlinear_runtime.py. Tests or test support files (2): test_block10_execution_persistence.py, test_nonlinear_execution.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.10 komorebi_math.nonlinear.filtered

Purpose and source. Finite filtered obstructions, lift completion, and spectral-sequence records. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/filtered.py contains 844 lines and 36,672 bytes. Source SHA-256 begins 9209ff4d05afcaf0.

Surface and ownership. API classification: API-manifested implementation owner. It owns 16 manifest cards: 0 stable, 0 beta, and 16 research. Linked cards: conditional_projective_limit_completion, FilteredCorrectionProblem, FilteredVectorSpace, FiniteFilteredCochainComplex, verify_finite_filtered_branch, conditional_projective_limit_completion, DepthObstructionResult, FilteredCorrectionProblem, FilteredSpectralSequenceResult, FilteredVectorSpace, and 6 more in the machine-readable ledger. Its __all__ declaration contains 11 names: conditional_projective_limit_completion, DepthObstructionResult, FilteredCorrectionProblem, FilteredSpectralSequenceResult, FilteredVectorSpace, FiniteFilteredBranchResult, FiniteFilteredCochainComplex, ProjectiveLimitRecord, SpectralSequenceEntry, SpectralSequencePage, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.nonlinear.lifting, komorebi_math.provenance. Reverse package dependents (4): komorebi_math, komorebi_math.export.persistence, komorebi_math.nonlinear, komorebi_math.verify.nonlinear_advanced. Examples (1): filtered_transport.py. Tests or test support files (3): test_block10_execution_persistence.py, test_nonlinear_filtered.py, test_nonlinear_snapshots_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.11 komorebi_math.nonlinear.gpu

Purpose and source. Optional CuPy execution for persisted packet-jet snapshots. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/gpu.py contains 205 lines and 7,670 bytes. Source SHA-256 begins 2a4ffa8606b9b8ea.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 0 stable, 0 beta, and 12 research. Linked cards: cupy_runtime_status, CuPyPacketJetSnapshotExecutor, CuPyRuntimeStatus, CuPySnapshotExecutor, CuPyValidationResult, validate_cupy_snapshot, cupy_runtime_status, CuPyPacketJetSnapshotExecutor, CuPyRuntimeStatus, CuPySnapshotExecutor, and 2 more in the machine-readable ledger. Its __all__ declaration contains 6 names: cupy_runtime_status, CuPyPacketJetSnapshotExecutor, CuPyRuntimeStatus, CuPySnapshotExecutor, CuPyValidationResult, validate_cupy_snapshot.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.nonlinear.snapshots`, `komorebi_math.provenance`. Reverse package dependents (3): `komorebi_math`, `komorebi_math.nonlinear`, `komorebi_math.verify.scalable_nonlinear`. Examples (1): `scalable_nonlinear.py`. Tests or test support files (2): `test_block10_execution_persistence.py`, `test_nonlinear_execution.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.12 `komorebi_math.nonlinear.graded`

Purpose and source. Finite graded nonlinear operations and packet Maurer-Cartan equations. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/graded.py` contains 633 lines and 25,862 bytes. Source SHA-256 begins `f751b044f309565a`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 16 manifest cards: 0 stable, 0 beta, and 16 research. Linked cards: divided_square_packets, FiniteAbelianGroup, GradedPacketOperation, higher_maurer_cartan_packets, maurer_cartan_packets, divided_square_packets, DividedSquareResult, FiniteAbelianGroup, GradedConvolutionResult, GradedConvolutionTerm, and 6 more in the machine-readable ledger. Its `__all__` declaration contains 11 names: `divided_square_packets`, `DividedSquareResult`, `FiniteAbelianGroup`, `GradedConvolutionResult`, `GradedConvolutionTerm`, `GradedPacketOperation`, `GradingCertificate`, `higher_maurer_cartan_packets`, `HigherMaurerCartanResult`, `maurer_cartan_packets`, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.core.packets`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (3): `komorebi_math`, `komorebi_math.nonlinear`, `komorebi_math.verify.nonlinear_advanced`. Examples (0): none. Tests or test support files (1): `test_nonlinear_graded.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.13 `komorebi_math.nonlinear.holonomy`

Purpose and source. Finite matrix transport, gauges, and holonomy certificates. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/holonomy.py` contains 329 lines and 14,597 bytes. Source SHA-256 begins `0cc4194ed31c8f57`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: TransportEdge, TransportGraph, FundamentalHolonomy, IntertwiningResult, TransportEdge, TransportGraph. Its `__all__` declaration contains 4 names: `FundamentalHolonomy`, `IntertwiningResult`, `TransportEdge`, `TransportGraph`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math.backends`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (4): `komorebi_math`, `komorebi_math.langlands.local.bridge`, `komorebi_math.nonlinear`, `komorebi_math.verify.nonlinear`. Examples (1): `holonomy.py`. Tests or test support files (1): `test_holonomy.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.14 `komorebi_math.nonlinear.jets`

Purpose and source. Packet jets, derivative reconstruction, support, and Taylor data. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/jets.py` contains 515 lines and 21,521 bytes. Source SHA-256 begins `913c9ede0ff13b43`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 16 manifest cards: 0 stable, 5 beta, and 11 research. Linked cards: packet_jet_support, PacketJet, PacketJetAddress, PacketJetFamily, PacketJetSupport, packet_jet_support, packet_taylor, PacketJet, PacketJetFamily, packet_jet_support, and 6 more in the machine-readable ledger. Its `__all__` declaration contains 8 names: `packet_jet_support`, `packet_taylor`, `PacketJet`, `PacketJetAddress`, `PacketJetFamily`, `PacketJetSupport`, `PacketLabel`, `PacketTaylorResult`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.core.packets`, `komorebi_math.exceptions`, `komorebi_math.nonlinea`

r.derivatives, komorebi_math.provenance. Reverse package dependents (14): komorebi_math, komorebi_math.beta, komorebi_math.export.persistence, komorebi_math.golden, komorebi_math.nonlinear, komorebi_math.nonlinear.composition, and 8 more in the machine-readable ledger. Examples (6): block11_semantic_profile.py, nonlinear_jets_composition.py, portable_nonlinear_state.py, resumable_packet_jet_stream.py, scalable_nonlinear.py, and 1 more in the machine-readable ledger. Tests or test support files (8): test_block10_execution_persistence.py, test_block11_cli.py, test_block11_golden_profiling_beta.py, test_block11_streaming_migrations.py, test_nonlinear_execution.py, and 3 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.15 komorebi_math.nonlinear.lifting

Purpose and source. Exact finite lifting over prime-power rings. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/lifting.py contains 480 lines and 18,927 bytes. Source SHA-256 begins d28ba65c3473b900.

Surface and ownership. API classification: API-manifested implementation owner. It owns 13 manifest cards: 0 stable, 0 beta, and 13 research. Linked cards: build_lift_tree, FiniteLiftTree, LinearLiftProblem, PolynomialLiftProblem, solve_mod_prime, build_lift_tree, FiniteLiftTree, LiftStepResult, LiftTreeNode, LinearLiftProblem, and 3 more in the machine-readable ledger. Its __all__ declaration contains 8 names: build_lift_tree, FiniteLiftTree, LiftStepResult, LiftTreeNode, LinearLiftProblem, ModularLinearSolution, PolynomialLiftProblem, solve_mod_prime.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (6): komorebi_math, komorebi_math.export.persistence, komorebi_math.langlands.local.symplectic, komorebi_math.nonlinear, komorebi_math.nonlinear.filtered, komorebi_math.verify.nonlinear. Examples (1): obstruction_lifting.py. Tests or test support files (2): test_block10_execution_persistence.py, test_lifting.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.16 komorebi_math.nonlinear.obstruction

Purpose and source. Finite-dimensional cokernel obstruction computations. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/obstruction.py contains 196 lines and 8,115 bytes. Source SHA-256 begins ed11236a44f5f571.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: LinearObstructionProblem, LinearObstructionProblem, ObstructionResult, ObstructionSquare. Its __all__ declaration contains 3 names: LinearObstructionProblem, ObstructionResult, ObstructionSquare.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (4): komorebi_math.backends, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (4): komorebi_math, komorebi_math.nonlinear, komorebi_math.unified, komorebi_math.verify.nonlinear. Examples (1): obstruction_lifting.py. Tests or test support files (1): test_nonlinear_obstruction.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.17 komorebi_math.nonlinear.profiling

Purpose and source. Operation counts and observational profiles for finite packet-jet runtimes. It is an ordinary module in the nonlinear family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/nonlinear/profiling.py contains 467 lines and 16,848 bytes. Source SHA-256 begins 034aa8498ddafce5.

Surface and ownership. API classification: API-manifested implementation owner. It owns 21 manifest cards: 0 stable, 7 beta, and 14 research. Linked cards: estimate_packet_jet_complexity, PacketJetComplexityEstimate, PacketJetProfileReport, profile_operation, profile_packet_jet_runtime, RuntimeProfileSample, RuntimeStageProfile, estimate_packet_jet_complexity, PacketJetComplexityEstimate, PacketJetProfileReport, and 11 more in the machine-readable ledger. Its __all__ declaration contains 7 names: estimate_packet_jet_complexity, PacketJetComplexityEstimate, PacketJetProfileReport, profile_operation, profile_packet_jet_runtime, RuntimeProfileSample, RuntimeStageProfile.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (8): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.export.persistence`, `komorebi_math.nonlinear.execution`, `komorebi_math.nonlinear.jets`, `komorebi_math.nonlinear.snapshots`, and 2 more in the machine-readable ledger. Reverse package dependents (4): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.nonlinear`, `komorebi_math.verify.streaming_beta`. Examples (1): `block11_semantic_profile.py`. Tests or test support files (1): `test_block11_golden_profiling_beta.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.18 `komorebi_math.nonlinear.snapshots`

Purpose and source. Portable finite snapshots of packet-jet blocks. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/snapshots.py` contains 375 lines and 15,205 bytes. Source SHA-256 begins `bd7a755c4b145b2f`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 0 stable, 3 beta, and 5 research. Linked cards: PacketJetCoefficient, PacketJetSnapshot, snapshot_packet_jet, PacketJetSnapshot, snapshot_packet_jet, PacketJetCoefficient, PacketJetSnapshot, snapshot_packet_jet. Its `__all__` declaration contains 3 names: `PacketJetCoefficient`, `PacketJetSnapshot`, `snapshot_packet_jet`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.nonlinear.jets`, `komorebi_math.provenance`. Reverse package dependents (10): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.export.persistence`, `komorebi_math.golden`, `komorebi_math.nonlinear`, `komorebi_math.nonlinear.gpu`, and 4 more in the machine-readable ledger. Examples (2): `portable_nonlinear_state.py`, `scalable_nonlinear.py`. Tests or test support files (4): `test_block10_execution_persistence.py`, `test_block11_cli.py`, `test_block11_streaming_migrations.py`, `test_nonlinear_snapshots_persistence.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.19 `komorebi_math.nonlinear.sparse`

Purpose and source. Sparse symmetric derivative tensors and polynomial derivative providers. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/sparse.py` contains 660 lines and 28,243 bytes. Source SHA-256 begins `f4d37624c5797b83`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 3 beta, and 6 research. Linked cards: SparsePolynomialDerivativeProvider, SparseSymmetricTensor, SparseTensorEntry, SparsePolynomialDerivativeProvider, SparseSymmetricTensor, SparseTensorEntry, SparsePolynomialDerivativeProvider, SparseSymmetricTensor, SparseTensorEntry. Its `__all__` declaration contains 3 names: `SparsePolynomialDerivativeProvider`, `SparseSymmetricTensor`, `SparseTensorEntry`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.nonlinear.derivatives`, `komorebi_math.provenance`. Reverse package dependents (6): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.export.persistence`, `komorebi_math.golden`, `komorebi_math.nonlinear`, `komorebi_math.verify.scalable_nonlinear`. Examples (2): `scalable_nonlinear.py`, `scalable_nonlinear_runtime.py`. Tests or test support files (4): `test_block10_execution_persistence.py`, `test_block10_sparse_autodiff.py`, `test_nonlinear_snapshots_persistence.py`, `test_nonlinear_sparse_autodiff.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.20 `komorebi_math.nonlinear.streaming`

Purpose and source. Chunked, resumable persistence for finite packet-jet snapshots. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/streaming.py` contains 1,664 lines and 65,296 bytes. Source SHA-256 begins `b4db5f4d1493421b`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 30 manifest cards: 0 stable, 10 beta, and 20 research. Linked cards: capture_packet_jet_stream, load_packet_jet_snapshot_stream, open_packet_jet_snapshot_stream, PacketJetSnapshotStreamReader, PacketJetStreamChunkRecord, PacketJetStreamManifest, PacketJetStreamSelection, PacketJetStreamWriteResult, save_packet_jet_snapshot_stream,

StreamedPacketJetEvaluation, and 20 more in the machine-readable ledger. Its `__all__` declaration contains 14 names: `capture_packet_jet_stream`, `load_packet_jet_snapshot_stream`, `open_packet_jet_snapshot_stream`, `PACKET_JET_CHUNK_SCHEMA`, `PACKET_JET_CHUNK_SCHEMA_VERSION`, `PACKET_JET_STREAM_SCHEMA`, `PACKET_JET_STREAM_SCHEMA_VERSION`, `PacketJetSnapshotStreamReader`, `PacketJetStreamChunkRecord`, `PacketJetStreamManifest`, and 4 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (7): `komorebi_math._version`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.export.persistence`, `komorebi_math.nonlinear.jets`, `komorebi_math.nonlinear.snapshots`, and 1 more in the machine-readable ledger. Reverse package dependents (7): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.cli.main`, `komorebi_math.golden`, `komorebi_math.nonlinear`, `komorebi_math.nonlinear.profiling`, and 1 more in the machine-readable ledger. Examples (1): `resumable_packet_jet_stream.py`. Tests or test support files (2): `test_block11_cli.py`, `test_block11_streaming_migrations.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.21 `komorebi_math.nonlinear.transport`

Purpose and source. Smooth transport for finite moving orthogonal packet systems. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/transport.py` contains 472 lines and 19,763 bytes. Source SHA-256 begins `8b11db4ddeca0bd0`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: direct_packet_rotation, KatoTransport, MovingPacketSystem, direct_packet_rotation, DirectRotationResult, KatoTransport, MovingPacketSystem, PacketDerivativeResult, TransportRefinementResult. Its `__all__` declaration contains 6 names: `direct_packet_rotation`, `DirectRotationResult`, `KatoTransport`, `MovingPacketSystem`, `PacketDerivativeResult`, `TransportRefinementResult`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.dynamics._linalg`, `komorebi_math.exceptions`, `komorebi_math.provenance`. Reverse package dependents (4): `komorebi_math`, `komorebi_math.nonlinear`, `komorebi_math.quantum.kato`, `komorebi_math.verify.nonlinear_advanced`. Examples (1): `filtered_transport.py`. Tests or test support files (1): `test_nonlinear_transport.py`. Documentation files with literal module or public-route references (2): `API_STABILITY_REVIEW.md`, `BLOCK_9_RELEASE.md`. AST parsing and runtime import both passed in the recorded module audit.

D.2.14.22 `komorebi_math.nonlinear.trees`

Purpose and source. Ordered rooted-tree expansions for polynomial nonlinear fixed points. It is an ordinary module in the `nonlinear` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/nonlinear/trees.py` contains 739 lines and 27,451 bytes. Source SHA-256 begins `94ce7611a8552386`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 18 manifest cards: 0 stable, 0 beta, and 18 research. Linked cards: majorant_convergence, OrderedRootedTree, packet_tree_reconstruction, PolynomialFixedPointProblem, quadratic_catalan_majorant, catalan_number, majorant_convergence, MajorantConvergence, ordered_rooted_trees, ordered_tree_count, and 8 more in the machine-readable ledger. Its `__all__` declaration contains 14 names: `catalan_number`, `majorant_convergence`, `MajorantConvergence`, `MultilinearOperation`, `ordered_rooted_trees`, `ordered_tree_count`, `ordered_trees_with_leaves`, `OrderedRootedTree`, `packet_tree_reconstruction`, `PacketTreeResult`, and 4 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.core.packets`, `komorebi_math.exceptions`, `komorebi_math.nonlinear.jets`, `komorebi_math.provenance`. Reverse package dependents (4): `komorebi_math`, `komorebi_math.export.persistence`, `komorebi_math.nonlinear`, `komorebi_math.verify.nonlinear_advanced`. Examples (1): `nonlinear_trees_elimination.py`. Tests or test support files (3): `test_block10_execution_persistence.py`, `test_nonlinear_snapshots_persistence.py`, `test_nonlinear_trees.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15 Integration: 8 modules

D.2.15.1 `komorebi_math.integration`

Purpose and source. General finite measure integration for the research API. It is the package initializer for the `integration` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/integration/__init__.py` contains 89 lines and 2,385 bytes. Source SHA-256 begins `43776914f55055c7`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 38 names: `affine_interval_change_of_variables`, `all_fubini_orders`, `analysis_synthesis_integration_certificate`, `AtomicIntegratedDerivativeProvider`, `AtomicMeasure`, `CompositeSimpson`, `coordinate_fundamental_theorem`, `coordinate_transport_identity`, `DerivativeBound`, `ErrorGuarantee`, and 28 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): `komorebi_math.integration.adapters`, `komorebi_math.integration.coordinates`, `komorebi_math.integration.identities`, `komorebi_math.integration.measures`, `komorebi_math.integration.polynomial`, `komorebi_math.integration.quadrature`, and 1 more in the machine-readable ledger. Reverse package dependents (2): `komorebi_math`, `komorebi_math.verify.integration`. Examples (1): `block19_measure_integration_worked_example.py`. Tests or test support files (1): `test_block19_integration.py`. Documentation files with literal module or public-route references (1): `PUBLIC_API.md`. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.2 `komorebi_math.integration.adapters`

Purpose and source. Adapters from existing coordinate, series, derivative, and frame calculi. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/adapters.py` contains 408 lines and 16,614 bytes. Source SHA-256 begins `9b8a3651c643a7a2`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 6 manifest cards: 0 stable, 0 beta, and 6 research. Linked cards: analysis_synthesis_integration_certificate, AtomicIntegratedDerivativeProvider, integrate_formal_series, integrate_polynomial_coordinates, polynomial_from_family_coordinates, polynomial_from_formal_series. Its `__all__` declaration contains 6 names: `analysis_synthesis_integration_certificate`, `AtomicIntegratedDerivativeProvider`, `integrate_formal_series`, `integrate_polynomial_coordinates`, `polynomial_from_family_coordinates`, `polynomial_from_formal_series`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (8): `komorebi_math.certificates`, `komorebi_math.coordinates.analysis_synthesis`, `komorebi_math.coordinates.polynomials`, `komorebi_math.exceptions`, `komorebi_math.generating.series`, `komorebi_math.integration.measures`, and 2 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.integration`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.3 `komorebi_math.integration.coordinates`

Purpose and source. Integration covectors in arbitrary exact polynomial coordinates. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/coordinates.py` contains 371 lines and 13,498 bytes. Source SHA-256 begins `687601788d64e15f`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: coordinate_fundamental_theorem, coordinate_transport_identity, polynomial_integration_covector, PolynomialIntegrationCovector. Its `__all__` declaration contains 4 names: `coordinate_fundamental_theorem`, `coordinate_transport_identity`, `polynomial_integration_covector`, `PolynomialIntegrationCovector`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (8): `komorebi_math.certificates`, `komorebi_math.coordinates.calculus`, `komorebi_math.coordinates.polynomials`, `komorebi_math.exceptions`, `komorebi_math.integration.identities`, `komorebi_math.integration.measures`, and 2 more in the machine-readable ledger. Reverse package dependents

(1): `komorebi_math.integration`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.4 `komorebi_math.integration.identities`

Purpose and source. Exact finite integral identities with replayable witness data. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/identities.py` contains 341 lines and 13,394 bytes. Source SHA-256 begins `5a323effecd17cde`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 7 manifest cards: 0 stable, 0 beta, and 7 research. Linked cards: affine_interval_change_of_variables, all_fubini_orders, fubini_identity, fundamental_theorem, IntegralIdentity, integration_by_parts, pushforward_identity. Its `__all__` declaration contains 7 names: `affine_interval_change_of_variables`, `all_fubini_orders`, `fubini_identity`, `fundamental_theorem`, `IntegralIdentity`, `integration_by_parts`, `pushforward_identity`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.integration.measures`, `komorebi_math.integration.polynomial`, `komorebi_math.integration.quadrature`. Reverse package dependents (2): `komorebi_math.integration`, `komorebi_math.integration.coordinates`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.5 `komorebi_math.integration.measures`

Purpose and source. Finite measure objects and exact pushforward semantics. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/measures.py` contains 1,090 lines and 44,458 bytes. Source SHA-256 begins `8afd4b87c10b7309`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 0 stable, 0 beta, and 8 research. Linked cards: AtomicMeasure, ExactAffineMap, IntervalMeasure, Measure, product_measure, ProductMeasure, pushforward_measure, PushforwardMeasure. Its `__all__` declaration contains 9 names: `AtomicMeasure`, `ExactAffineMap`, `IntervalMeasure`, `Measure`, `product_measure`, `ProductMeasure`, `pushforward_measure`, `PushforwardMeasure`, `RealScalar`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.coordinates.exact`, `komorebi_math.exceptions`, `komorebi_math.integration.polynomial`, `komorebi_math.integration.quadrature`. Reverse package dependents (6): `komorebi_math.integration`, `komorebi_math.integration.adapters`, `komorebi_math.integration.coordinates`, `komorebi_math.integration.identities`, `komorebi_math.integration.quadrature`, `komorebi_math.integration.rules`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.6 `komorebi_math.integration.polynomial`

Purpose and source. Exact finite multivariate polynomials for measure integration. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/polynomial.py` contains 373 lines and 15,731 bytes. Source SHA-256 begins `f4f739bafd6ab4da`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: ExactPolynomial. Its `__all__` declaration contains 4 names: `ExactPolynomial`, `Exponent`, `Rational`, `Term`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (7): `komorebi_math.integration`, `komorebi_math.integration.adapters`, `komorebi_math.integration.coordinates`, `komorebi_math.integration.identities`, `komorebi_math.integration.measures`, `komorebi_math.integration.quadrature`, and 1 more in the machine-readable ledger. Examples (0): none. Tests or test support files

(0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.7 `komorebi_math.integration.quadrature`

Purpose and source. Generic integration dispatch and honest quadrature error semantics. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/quadrature.py` contains 1,261 lines and 49,338 bytes. Source SHA-256 begins `0b48e7ee5eb5b42c`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 9 manifest cards: 0 stable, 0 beta, and 9 research. Linked cards: CompositeSimpson, DerivativeBound, ErrorGuarantee, IntegralResult, integrate, integrate_derivative_provider, integrate_polynomial_oriented, IntegrationError, polynomial_derivative_bound. Its `__all__` declaration contains 9 names: `CompositeSimpson`, `DerivativeBound`, `ErrorGuarantee`, `IntegralResult`, `integrate`, `integrate_derivative_provider`, `integrate_polynomial_oriented`, `IntegrationError`, `polynomial_derivative_bound`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.integration.measures`, `komorebi_math.integration.polynomial`. Reverse package dependents (6): `komorebi_math.integration`, `komorebi_math.integration.adapters`, `komorebi_math.integration.coordinates`, `komorebi_math.integration.identities`, `komorebi_math.integration.measures`, `komorebi_math.integration.rules`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.15.8 `komorebi_math.integration.rules`

Purpose and source. Signed quadrature functionals kept distinct from positive measures. It is an ordinary module in the `integration` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/integration/rules.py` contains 526 lines and 21,223 bytes. Source SHA-256 begins `ba0e8d7ad4154999`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: ExactQuadratureRule, QuadratureExactness, QuadratureRule. Its `__all__` declaration contains 3 names: `ExactQuadratureRule`, `QuadratureExactness`, `QuadratureRule`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.integration.measures`, `komorebi_math.integration.polynomial`, `komorebi_math.integration.quadrature`. Reverse package dependents (1): `komorebi_math.integration`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16 Dynamics: 12 modules

D.2.16.1 `komorebi_math.dynamics`

Purpose and source. Semigroups, probabilistic refinement, fractional operators, and memory. It is the package initializer for the `dynamics` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/dynamics/__init__.py` contains 112 lines and 2,815 bytes. Source SHA-256 begins `e4c6b8fdf58de468`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 43 names: `aggregation_matrix`, `AggregationMap`, `approximate_likelihood_partition`, `BayesianFlow`, `BayesianPartition`, `BayesianUpdate`, `coarsest_sufficient_partition`, `ConditionalExpectation`, `ConditionalExpectationTower`, `ContinuousTimeMarkovChain`, and 33 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (12): `komorebi_math._planned`, `komorebi_math.dynamics.bayes`, `komorebi_math.dynamics.feshbach`, `komorebi_math.dynamics.feynman_kac`, `komorebi_math.dynamics.fractional`, `komorebi_math.dynamics.green`, and 6 more in the machine-readable ledger. Reverse package dependents

(4): komorebi_math, komorebi_math.quantum.effective, komorebi_math.verify.dynamics, komorebi_math.verify.quantum. Examples (5): feshbach_memory.py, filtered_transport.py, fractional_survival.py, kato_feshbach.py, markov_bayes.py. Tests or test support files (7): test_block4_hardening.py, test_dynamics_bayes_martingales.py, test_dynamics_feshbach.py, test_dynamics_fractional_green_feynman_survival.py, test_dynamics_semigroups_markov.py, and 2 more in the machine-readable ledger. Documentation files with literal module or public-route references (2): API_INVENTORY.md, PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.2 komorebi_math.dynamics._linalg

Purpose and source. Small matrix functions used by the finite dynamics layer. It is an ordinary module in the dynamics family. The ledger classifies it as an internal support module. Source src/komorebi_math/dynamics/_linalg.py contains 117 lines and 4,672 bytes. Source SHA-256 begins 3b75d5e7183b8b78.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 4 names: as_square_matrix, block_partition, hermitian_fractional_power, matrix_exponential.

Dependencies and evidence. Direct dependency profile: optional scientific extra, required NumPy dependency. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (12): komorebi_math.analytic.sections, komorebi_math.dynamics.feshbach, komorebi_math.dynamics.feynman_kac, komorebi_math.dynamics.markov, komorebi_math.dynamics.memory, komorebi_math.dynamics.semigroups, and 6 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.3 komorebi_math.dynamics.bayes

Purpose and source. Finite Bayesian updates, sufficient partitions, flows, and coarse filters. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/bayes.py contains 448 lines and 18,979 bytes. Source SHA-256 begins da5215d0b6a8be7c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: BayesianUpdate. Its __all__ declaration contains 8 names: approximate_likelihood_partition, BayesianFlow, BayesianPartition, BayesianUpdate, coarsest_sufficient_partition, HiddenMarkovFilter, relative_entropy, relative_entropy_decomposition.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.dynamics.markov, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.4 komorebi_math.dynamics.feshbach

Purpose and source. Finite Schur Feshbach reduction and exact hidden state memory. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/feshbach.py contains 196 lines and 7,882 bytes. Source SHA-256 begins b011baa1ebef8aa2.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: FeshbachReduction. Its __all__ declaration contains 1 name: FeshbachReduction.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.dynamics.memory, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.5 komorebi_math.dynamics.feynman_kac

Purpose and source. Finite-state Feynman-Kac transfer operators. It is an ordinary module in the dynamics family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/dynamics/feynman_kac.py contains 185 lines and 8,371 bytes. Source SHA-256 begins 49c17e4210904781.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 2 names: FeynmanKacKind, FiniteFeynmanKac.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.dynamics.markov, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.6 komorebi_math.dynamics.fractional

Purpose and source. Finite positive fractional operators and refinement certificates. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/fractional.py contains 184 lines and 7,094 bytes. Source SHA-256 begins 90b600829c896cdb.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: fractional_power. Its __all__ declaration contains 5 names: fractional_defect, fractional_naturality_certificate, fractional_power, fractional_semigroup, FractionalDefectResult.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.7 komorebi_math.dynamics.green

Purpose and source. Exact one-dimensional finite-difference Green operators. It is an ordinary module in the dynamics family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/dynamics/green.py contains 88 lines and 3,171 bytes. Source SHA-256 begins b757cff0bfdfaf24.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: DirichletGreen1D.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.8 komorebi_math.dynamics.markov

Purpose and source. Finite Markov operators, aggregation maps, and exact lumping diagnostics. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/markov.py contains 425 lines and 18,121 bytes. Source SHA-256 begins adc03fae56e58430.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: MarkovLumping. Its __all__ declaration contains 8 names: aggregation_matrix, AggregationMap, ContinuousTimeMarkovChain, coordinate_lumpability_residual, FiniteMarkovChain, MarkovKind, MarkovLumping, normalize_partition.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.

provenance. Reverse package dependents (3): komorebi_math.dynamics, komorebi_math.dynamics.bayes, komorebi_math.dynamics.feynman_kac. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.9 komorebi_math.dynamics.martingales

Purpose and source. Finite conditional expectations and martingale packet towers. It is an ordinary module in the dynamics family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/dynamics/martingales.py contains 234 lines and 9,795 bytes. Source SHA-256 begins afabfcd820079bb9.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 5 names: blocks_from_labels, ConditionalExpectation, ConditionalExpectationTower, MartingaleTower, partition_refines.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.10 komorebi_math.dynamics.memory

Purpose and source. Finite rational memory kernels, auxiliary realizations, and stability bounds. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/memory.py contains 320 lines and 12,890 bytes. Source SHA-256 begins 9a63a0123887def3.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: MemoryKernel. Its __all__ declaration contains 6 names: kernel_l1_error, memory_kernel_error_bound, MemoryKernel, RationalMemoryKernel, RationalMemoryRealization, volterra_trajectory_bound.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (2): komorebi_math.dynamics, komorebi_math.dynamics.feshbach. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.11 komorebi_math.dynamics.semigroups

Purpose and source. Finite matrix semigroups, packet blocks, and refinement defects. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/semigroups.py contains 342 lines and 14,304 bytes. Source SHA-256 begins 3e905fdef4dc9eec.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: MatrixSemigroup. Its __all__ declaration contains 7 names: FiniteSemigroupTower, matrix_exponential, MatrixSemigroup, PacketSemigroup, ProjectiveSemigroupTower, semigroup_refinement_defect, SemigroupRefinement.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.core, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (2): komorebi_math.dynamics, komorebi_math.dynamics.survival. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.16.12 komorebi_math.dynamics.survival

Purpose and source. Finite phase-type survival and competing risk packets. It is an ordinary module in the dynamics family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/dynamics/survival.py contains 193 lines and 8,097 bytes. Source SHA-256 begins a02759b3a1b01c4c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: PhaseTypeSurvival. Its __all__ declaration contains 1 name: PhaseTypeSurvival.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.dynamics.semigroups, komorebi_math.exceptions, komorebi_math.provenance. Reverse package dependents (1): komorebi_math.dynamics. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17 Quantum: 15 modules

D.2.17.1 komorebi_math.quantum

Purpose and source. Finite quantum packet calculus, channels, transport, and diagnostics. It is the package initializer for the quantum family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/quantum/__init__.py contains 107 lines and 3,031 bytes. Source SHA-256 begins 03d21a689ca36e84.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 46 names: amplitude_damping, BoundedHamiltonianTower, ChannelPacketBlock, charge_certificate, charge_selection_certificate, CircuitPacketExpansion, CircuitPathAmplitude, computational_basis_generation, constraint_closure, ConstraintClosureReport, and 36 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (15): komorebi_math._planned, komorebi_math.quantum.channels, komorebi_math.quantum.circuits, komorebi_math.quantum.constraints, komorebi_math.quantum.effective, komorebi_math.quantum.error_correction, and 9 more in the machine-readable ledger. Reverse package dependents (2): komorebi_math, komorebi_math.verify.quantum. Examples (4): euclidean_spectral.py, kato_feshbach.py, quantum_channel_qec.py, quantum_symmetry_circuit.py. Tests or test support files (4): test_nonlinear_transport.py, test_quantum_channels_qec.py, test_quantum_symmetry_circuits.py, test_quantum_transport_effective_spectral.py. Documentation files with literal module or public-route references (5): API_INVENTORY.md, API_STABILITY_REVIEW.md, BLOCK_9_RELEASE.md, NONLINEAR_CALCULUS.md, PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.2 komorebi_math.quantum._validation

Purpose and source. Validation helpers for finite quantum models. It is an ordinary module in the quantum family. The ledger classifies it as an internal support module. Source src/komorebi_math/quantum/_validation.py contains 126 lines and 4,812 bytes. Source SHA-256 begins 76c9e6aa914ad834.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 8 names: as_matrix, as_square_matrix, as_vector, density_matrix, orthogonal_packet_family, require_hermitian, require_projector, require_unitary.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (1): komorebi_math.exceptions. Reverse package dependents (12): komorebi_math.quantum.channels, komorebi_math.quantum.circuits, komorebi_math.quantum.constraints, komorebi_math.quantum.effective, komorebi_math.quantum.error_correction, komorebi_math.quantum.euclidean, and 6 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.3 komorebi_math.quantum.channels

Purpose and source. Finite quantum channels, operator packets, Choi matrices, and covariance. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/channels.py contains 269 lines and 11,511 bytes. Source SHA-256 begins 956acd703044a0ba.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: QuantumChannel. Its __all__ declaration contains 6 names: amplitude_damping, ChannelPacketBlock, dephase, operator_packets, QuantumChannel, reconstruct_operator_packets.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.core, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (2): komorebi_math.quantum, komorebi_math.quantum.error_correction. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.4 komorebi_math.quantum.circuits

Purpose and source. Exact finite quantum circuit packet path expansions. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/circuits.py contains 199 lines and 8,725 bytes. Source SHA-256 begins 49c75d8b5fb23c57.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: CircuitPacketExpansion. Its __all__ declaration contains 3 names: CircuitPacketExpansion, CircuitPathAmplitude, InterferenceReport.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.core, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.5 komorebi_math.quantum.constraints

Purpose and source. Finite constraint closure and refinement anomaly diagnostics. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/constraints.py contains 102 lines and 4,294 bytes. Source SHA-256 begins 4709fae78ee0879a.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: constraint_closure. Its __all__ declaration contains 3 names: constraint_closure, ConstraintClosureReport, transported_constraint_defect.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.6 komorebi_math.quantum.effective

Purpose and source. Hermitian Feshbach reduction and hidden quantum memory. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/effective.py contains 98 lines and 3,958 bytes. Source SHA-256 begins bcc39f27082afbce.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: QuantumFeshbachReduction. Its __all__ declaration contains 1 name: QuantumFeshbachReduction.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.dynamics, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none.

Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.7 komorebi_math.quantum.error_correction

Purpose and source. Finite quantum error correction through Knill-Laflamme compression. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/error_correction.py contains 162 lines and 7,675 bytes. Source SHA-256 begins 63929c14114a1271.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: QuantumCode. Its __all__ declaration contains 2 names: KnillLaflammeReport, QuantumCode.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation, komorebi_math.quantum.channels. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.8 komorebi_math.quantum.euclidean

Purpose and source. Finite Euclidean transfer operators and reflection positivity. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/euclidean.py contains 130 lines and 5,771 bytes. Source SHA-256 begins b93ca15e938e2775.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: EuclideanTransfer. Its __all__ declaration contains 1 name: EuclideanTransfer.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.9 komorebi_math.quantum.kato

Purpose and source. Backward-compatible quantum exports for shared smooth packet transport. It is an ordinary module in the quantum family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/quantum/kato.py contains 19 lines and 456 bytes. Source SHA-256 begins 5358211f57124e3f.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 6 names: direct_packet_rotation, DirectRotationResult, KatoTransport, MovingPacketSystem, PacketDerivativeResult, TransportRefinementResult.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.nonlinear.transport. Reverse package dependents (2): komorebi_math.quantum, komorebi_math.quantum.leakage. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (1): API_STABILITY_REVIEW.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.10 komorebi_math.quantum.leakage

Purpose and source. Fixed and moving packet leakage bounds. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/leakage.py contains 136 lines and 4,765 bytes. Source SHA-256 begins 5f29ee27743076ec.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: fixed_packet_leakage. Its __all__ declaration contains 4 names: fixed_packet_leakage, LeakageResult, moving_geometric_coupling, moving_packet_leakage_bound.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.

provenance, komorebi_math.quantum._validation, komorebi_math.quantum.kato. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.11 komorebi_math.quantum.lindblad

Purpose and source. Finite Lindblad generators and cyclic coherence packets. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/lindblad.py contains 121 lines and 5,251 bytes. Source SHA-256 begins 27480c2a9ab227d0.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: LindbladGenerator. Its __all__ declaration contains 1 name: LindbladGenerator.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.12 komorebi_math.quantum.seeds

Purpose and source. Finite quantum seed systems and local orbit dimensions. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/seeds.py contains 168 lines and 5,861 bytes. Source SHA-256 begins 81fdd926c0415333.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: QuantumSeedSystem. Its __all__ declaration contains 5 names: computational_basis_generation, local_orbit_dimension, observable_seed_rank, QuantumSeedSystem, schmidt_rank.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.core, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.13 komorebi_math.quantum.spectral

Purpose and source. Finite spectral dimension and periodic lattice diagnostics. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/spectral.py contains 143 lines and 5,815 bytes. Source SHA-256 begins 1b6f2b6f4c6b1664.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: periodic_laplacian, spectral_dimension. Its __all__ declaration contains 5 names: heat_trace, low_mode_dispersion_bound, periodic_laplacian, periodic_lattice_eigenvalues, spectral_dimension.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.14 komorebi_math.quantum.symmetry

Purpose and source. Finite group, cyclic charge, and tensor symmetry packets. It is an ordinary module in the quantum family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/quantum/symmetry.py contains 188 lines and 6,896 bytes. Source SHA-256 begins 3696b4f2db5045b2.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: cyclic_symmetry_projectors. Its __all__ declaration contains 6 names: charge_certificate, charge_selection_certificate, cyclic_symmetry_projectors, finite_group_projector, symmetry_projector_certificate, total_charge_packets.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): komorebi_math.certificates, komorebi_math.core, komorebi_math.exceptions, komorebi_math.provenance, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.17.15 komorebi_math.quantum.towers

Purpose and source. Finite bounded Hamiltonian towers and compatibility diagnostics. It is an ordinary module in the quantum family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/quantum/towers.py contains 80 lines and 3,363 bytes. Source SHA-256 begins 5236b88b39304556.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 2 names: BoundedHamiltonianTower, HamiltonianTowerReport.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.dynamics._linalg, komorebi_math.exceptions, komorebi_math.quantum._validation. Reverse package dependents (1): komorebi_math.quantum. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.18 Deformation: 7 modules

D.2.18.1 komorebi_math.deformation

Purpose and source. Finite residual deformation, support, and companion models. It is the package initializer for the deformation family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/deformation/__init__.py contains 85 lines and 2,107 bytes. Source SHA-256 begins c7d52eec665158f0.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 32 names: CohomologyData, CompanionForest, CompatibleCarrier, diagonal_nilpotent_count, FEATURE_KEY, FiberSupportResult, finite_frobenius_separator, FiniteCochainComplex, FiniteLiftForest, FittingGenerators, and 22 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (8): komorebi_math._planned, komorebi_math.deformation.companions, komorebi_math.deformation.complexes, komorebi_math.deformation.counting, komorebi_math.deformation.forests, komorebi_math.deformation.support, and 2 more in the machine-readable ledger. Reverse package dependents (3): komorebi_math, komorebi_math.cli.main, komorebi_math.verify.deformation. Examples (2): deformation_support.py, frobenius_companions.py. Tests or test support files (4): test_block10_execution_persistence.py, test_deformation_complex_support_companions.py, test_deformation_forests_visibility_counting.py, test_nonlinear_snapshots_persistence.py. Documentation files with literal module or public-route references (1): PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.18.2 komorebi_math.deformation.companions

Purpose and source. Finite companion forests, Frobenius spines, and trace separation. It is an ordinary module in the deformation family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/deformation/companions.py contains 276 lines and 11,291 bytes. Source SHA-256 begins d0e1870a622976a6.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: finite_frobenius_separator, FrobeniusSpine. Its __all__ declaration contains 5 names: CompanionForest, CompatibleCarrier, finite_frobenius_separator, FrobeniusSeparationResult, FrobeniusSpine.

Dependencies and evidence. Direct dependency profile: optional exact extra. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.deformation.forests, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.deformation. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.18.3 komorebi_math.deformation.complexes

Purpose and source. Finite cochain complexes and packetwise cohomology over prime fields. It is an ordinary module in the deformation family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/deformation/complexes.py contains 234 lines and 9,961 bytes. Source SHA-256 begins 436b06399cb0b4e7.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: FiniteCochainComplex. Its __all__ declaration contains 3 names: CohomologyData, FiniteCochainComplex, row_rank_mod.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (4): komorebi_math.deformation, komorebi_math.deformation.support, komorebi_math.langlands.local.bridge, komorebi_math.langlands.local.symplectic. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.18.4 komorebi_math.deformation.counting

Purpose and source. Exact finite-level counts for basic deformation charts. It is an ordinary module in the deformation family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/deformation/counting.py contains 143 lines and 5,074 bytes. Source SHA-256 begins 5f9171cbf1899f54.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 9 names: diagonal_nilpotent_count, nilpotent_chart_count, nilpotent_chart_series, normal_crossing_count, normal_crossing_series, RationalCountingSeries, smooth_chart_count, smooth_chart_series, weighted_chart_count.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math._number_theory, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.deformation. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.18.5 komorebi_math.deformation.forests

Purpose and source. Finite residual lift forests and stable inverse-system cores. It is an ordinary module in the deformation family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/deformation/forests.py contains 226 lines and 8,897 bytes. Source SHA-256 begins 3721563aea386fe8.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: FiniteLiftForest. Its __all__ declaration contains 4 names: FiniteLiftForest, LiftBranch, LiftForestReport, residue_forest.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (3): `komorebi_math.deformation`, `komorebi_math.deformation.companions`, `komorebi_math.export.persistence`. Examples (0): none. Tests or test support files (1): `test_nonlinear_snapshots_persistence.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.18.6 `komorebi_math.deformation.support`

Purpose and source. Finite presentation, Fitting, support, and occupancy calculations. It is an ordinary module in the `deformation` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/deformation/support.py` contains 240 lines and 9,423 bytes. Source SHA-256 begins `be6bffe1f6a8cbb4`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: PresentedModule. Its `__all__` declaration contains 5 names: `FiberSupportResult`, `FittingGenerators`, `nested_subspace_occupancy`, `NestedOccupancyResult`, `PresentedModule`.

Dependencies and evidence. Direct dependency profile: optional `exact` extra, required NumPy dependency. Direct package dependencies (4): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.deformation.complexes`, `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.deformation`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.18.7 `komorebi_math.deformation.visibility`

Purpose and source. Prime-adic visibility partitions and cluster trees. It is an ordinary module in the `deformation` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/deformation/visibility.py` contains 121 lines and 4,386 bytes. Source SHA-256 begins `3b61d0116228a469`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: VisibilityTree. Its `__all__` declaration contains 3 names: `rational_valuation`, `VisibilityPair`, `VisibilityTree`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math._number_theory`, `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.deformation`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19 Langlands: 24 modules

D.2.19.1 `komorebi_math.langlands`

Purpose and source. Finite local, global diagnostic, finite image, ramification, and completion models. It is the package initializer for the `langlands` family. The ledger classifies it as an importable package facade outside API manifests. Source `src/komorebi_math/langlands/__init__.py` contains 5 lines and 238 bytes. Source SHA-256 begins `13d0d7c50d0fdb80`.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 5 names: `completion`, `finite_image`, `global_`, `local`, `ramification`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): `komorebi_math.langlands.completion`, `komorebi_math.langlands.finite_image`, `komorebi_math.langlands.global_`, `komorebi_math.langlands.local`, `komorebi_math.langlands.ramification`. Reverse package dependents (0): none. Examples (3): `finite_image_clifford.py`, `ramification_completion.py`, `tame_heisenberg.py`. Tests or test support files (4): `test_langlands_finite_image.py`, `test_langlands_local_fields_tame_gauss.py`, `test_langlands_local_heisenberg_symplectic.py`, `test_langlands_ramification_global_`

completion.py. Documentation files with literal module or public-route references (1): PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.2 komorebi_math.langlands.completion

Purpose and source. Gate-based conditional Langlands completion reports. It is the package initializer for the langlands family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/langlands/completion/__init__.py contains 38 lines and 786 bytes. Source SHA-256 begins cf6c28c2492cd2c3.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 7 names: AutomorphicCompletionReport, CompatiblePropagationReport, CompletionGate, FEATURE_KEY, GateStatus, require, status.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math._planned, komorebi_math.langlands.completion.gates, komorebi_math.registry. Reverse package dependents (4): komorebi_math, komorebi_math.cli.main, komorebi_math.langlands, komorebi_math.verify.langlands. Examples (1): ramification_completion.py. Tests or test support files (1): test_langlands_ramification_global_completion.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.3 komorebi_math.langlands.completion.gates

Purpose and source. Explicit gate reports for conditional Langlands completion. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/completion/gates.py contains 119 lines and 4,369 bytes. Source SHA-256 begins 9eae5b42d05d6d49.

Surface and ownership. API classification: API-manifested implementation owner. It owns 4 manifest cards: 0 stable, 0 beta, and 4 research. Linked cards: AutomorphicCompletionReport, CompatiblePropagationReport, CompletionGate, GateStatus. Its __all__ declaration contains 4 names: AutomorphicCompletionReport, CompatiblePropagationReport, CompletionGate, GateStatus.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.langlands.completion. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.4 komorebi_math.langlands.finite_image

Purpose and source. Finite group, monomial packet, Mackey, and Clifford execution models. It is the package initializer for the langlands family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/langlands/finite_image/__init__.py contains 61 lines and 1,566 bytes. Source SHA-256 begins 6fa36cd624baf74d.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 23 names: AutomorphicInductionPlan, CliffordMode, CliffordStep, CliffordTower, CliffordTowerReport, compose_permutations, cyclic_group, FEATURE_KEY, FiniteGroup, FiniteSubgroup, and 13 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (8): komorebi_math._planned, komorebi_math.langlands.finite_image.characters, komorebi_math.langlands.finite_image.clifford, komorebi_math.langlands.finite_image.groups, komorebi_math.langlands.finite_image.mackey, komorebi_math.langlands.finite_image.orbits, and 2 more in the machine-readable ledger. Reverse package dependents (3): komorebi_math, komorebi_math.langlands, komorebi_math.verify.langlands. Examples (1): finite_image_clifford.py. Tests or test support files (1): test_langlands_finite_image.py. Documentation files with literal module or public-route references (1): PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.5 komorebi_math.langlands.finite_image.characters

Purpose and source. Linear characters and induced finite group representations. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/finite_image/characters.py contains 116 lines and 5,172 bytes. Source SHA-256 begins e0d6d96f440ba0a1.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: InducedRepresentation, LinearCharacter. Its __all__ declaration contains 2 names: InducedRepresentation, LinearCharacter.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.langlands.finite_image.groups. Reverse package dependents (4): komorebi_math.langlands.finite_image, komorebi_math.langlands.finite_image.mackey, komorebi_math.langlands.finite_image.orbits, komorebi_math.langlands.finite_image.plans. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.6 komorebi_math.langlands.finite_image.clifford

Purpose and source. Finite Clifford tower words, depth, and conditional descent plans. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/finite_image/clifford.py contains 202 lines and 8,052 bytes. Source SHA-256 begins 4c808f92dc3ed8fe.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: CliffordStep, CliffordTower. Its __all__ declaration contains 6 names: CliffordMode, CliffordStep, CliffordTower, CliffordTowerReport, VirtualCharacterResolution, VirtualCharacterTerm.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.langlands.finite_image. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.7 komorebi_math.langlands.finite_image.groups

Purpose and source. Small exact finite groups, subgroups, and permutation constructors. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/finite_image/groups.py contains 278 lines and 11,548 bytes. Source SHA-256 begins 46953d9eed271410.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: cyclic_group, FiniteGroup. Its __all__ declaration contains 5 names: compose_permutations, cyclic_group, FiniteGroup, FiniteSubgroup, symmetric_group.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (3): komorebi_math.langlands.finite_image, komorebi_math.langlands.finite_image.characters, komorebi_math.langlands.finite_image.mackey. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.8 komorebi_math.langlands.finite_image.mackey

Purpose and source. Finite Mackey double-coset packet data. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/finite_image/mackey.py contains 71 lines and 2,707 bytes. Source SHA-256 begins 2804cd9bed595227.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: mackey_tensor_packets. Its __all__ declaration contains 3 names: mackey_tensor_packets, MackeyDecomposition, MackeyPacket.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.langlands.

finite_image.characters, komorebi_math.langlands.finite_image.groups. Reverse package dependents (1): komorebi_math.langlands.finite_image. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.9 komorebi_math.langlands.finite_image.orbits

Purpose and source. Orbit packet decompositions for monomial tensor operations. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/finite_image/orbits.py contains 167 lines and 7,474 bytes. Source SHA-256 begins 828529d2ffa213f7.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: MonomialAction. Its __all__ declaration contains 3 names: MonomialAction, OrbitPacket, weak_compositions.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.langlands.finite_image.characters. Reverse package dependents (1): komorebi_math.langlands.finite_image. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.10 komorebi_math.langlands.finite_image.plans

Purpose and source. Symbolic automorphic induction plans for finite monomial parameters. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/finite_image/plans.py contains 47 lines and 1,949 bytes. Source SHA-256 begins 9004a8c55d653ba1.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: AutomorphicInductionPlan. Its __all__ declaration contains 1 name: AutomorphicInductionPlan.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.langlands.finite_image.characters. Reverse package dependents (1): komorebi_math.langlands.finite_image. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.11 komorebi_math.langlands.global_

Purpose and source. Conditional global support, Hecke packet, and patching models. It is the package initializer for the langlands family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/langlands/global_/__init__.py contains 37 lines and 895 bytes. Source SHA-256 begins 767c34a5eb0c1b3b.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 9 names: dyadic_sign_diagnostic, DyadicSignDiagnostic, FEATURE_KEY, FiniteHeckePackets, HeckePacket, PatchingSupportReport, require, status, SupportComparison.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (5): komorebi_math._planned, komorebi_math.langlands.global_.dyadic, komorebi_math.langlands.global_.hecke, komorebi_math.langlands.global_.patching, komorebi_math.registry. Reverse package dependents (3): komorebi_math, komorebi_math.langlands, komorebi_math.verify.langlands. Examples (0): none. Tests or test support files (1): test_langlands_ramification_global_completion.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.12 komorebi_math.langlands.global_.dyadic

Purpose and source. Coefficient-prime-two group algebra diagnostics. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/global_/dyadic.py contains 42 lines and 1,383 bytes. Source SHA-256 begins 9bacd8ed4d652c2d.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: dyadic_sign_diagnostic. Its __all__ declaration contains 2 names: dyadic_sign_diagnostic, DyadicSignDiagnostic.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (1): komorebi_math.certificates. Reverse package dependents (1): komorebi_math.langlands.global_. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.13 komorebi_math.langlands.global_.hecke

Purpose and source. Finite Hecke packet decompositions and support transport models. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/global_/hecke.py contains 137 lines and 5,783 bytes. Source SHA-256 begins 147eea0cf592a9b9.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: FiniteHeckePackets, SupportComparison. Its __all__ declaration contains 3 names: FiniteHeckePackets, HeckePacket, SupportComparison.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (1): komorebi_math.langlands.global_. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.14 komorebi_math.langlands.global_.patching

Purpose and source. Finite gate models for patched support and characteristic-zero fibers. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/global_/patching.py contains 69 lines and 2,657 bytes. Source SHA-256 begins 6bb134c099c63852.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: PatchingSupportReport. Its __all__ declaration contains 1 name: PatchingSupportReport.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.certificates. Reverse package dependents (1): komorebi_math.langlands.global_. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.15 komorebi_math.langlands.local

Purpose and source. Executable finite models for tame and wild local packet geometry. It is the package initializer for the langlands family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/langlands/local/__init__.py contains 63 lines and 1,682 bytes. Source SHA-256 begins cce8b2f7cd922550.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 24 names: additive_character, AlternatingForm, EnvelopeRecovery, FEATURE_KEY, FiniteField, FiniteFieldElement, FrobeniusOrbit, gauss_sum, GaussSumResult, HeisenbergElement, and 14 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (9): komorebi_math._planned, komorebi_math.langlands.local.bridge, komorebi_math.langlands.local.envelopes, komorebi_math.langlands.local.finite_fields, komorebi_

math.langlands.local.gauss, komorebi_math.langlands.local.heisenberg, and 3 more in the machine-readable ledger. Reverse package dependents (5): komorebi_math, komorebi_math.cli.main, komorebi_math.langlands, komorebi_math.langlands.ramification.towers, komorebi_math.verify.langlands. Examples (2): ramification_completion.py, tame_heisenberg.py. Tests or test support files (3): test_langlands_local_fields_tame_gauss.py, test_langlands_local_heisenberg_symplectic.py, test_langlands_ramification_global_completion.py. Documentation files with literal module or public-route references (1): PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.16 komorebi_math.langlands.local.bridge

Purpose and source. Finite packet bridge and holonomy diagnostics. It is an ordinary module in the langlands family. The ledger classifies it as unmanifested implementation support. Source src/komorebi_math/langlands/local/bridge.py contains 74 lines and 2,683 bytes. Source SHA-256 begins d602ecb7891d84c6.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 2 names: LocalPacketBridge, SymplecticBridge.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): komorebi_math.certificates, komorebi_math.deformation.complexes, komorebi_math.exceptions, komorebi_math.langlands.local.symplectic, komorebi_math.nonlinear, komorebi_math.nonlinear.holonomy. Reverse package dependents (1): komorebi_math.langlands.local. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.17 komorebi_math.langlands.local.envelopes

Purpose and source. Projective intertwiner envelopes and commutator forms. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/local/envelopes.py contains 104 lines and 4,663 bytes. Source SHA-256 begins 4b6469345802df9f.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: ProjectiveIntertwinerEnvelope. Its __all__ declaration contains 2 names: EnvelopeRecovery, ProjectiveIntertwinerEnvelope.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.langlands.local.symplectic. Reverse package dependents (1): komorebi_math.langlands.local. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.18 komorebi_math.langlands.local.finite_fields

Purpose and source. Small exact finite fields for local packet computations. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/local/finite_fields.py contains 365 lines and 13,731 bytes. Source SHA-256 begins 078140eafd796083.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: FiniteField. Its __all__ declaration contains 3 names: FiniteField, FiniteFieldElement, is_irreducible_polynomial.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math._number_theory, komorebi_math.exceptions. Reverse package dependents (2): komorebi_math.langlands.local, komorebi_math.langlands.local.gauss. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.19 `komorebi_math.langlands.local.gauss`

Purpose and source. Finite field Gauss sums and phase certificates. It is an ordinary module in the `langlands` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/langlands/local/gauss.py` contains 79 lines and 2,595 bytes. Source SHA-256 begins `a09ddf5c664e7017`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: gauss_sum. Its `__all__` declaration contains 4 names: `additive_character`, `gauss_sum`, `GaussSumResult`, `multiplicative_character`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.langlands.local.finite_fields`. Reverse package dependents (1): `komorebi_math.langlands.local`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.20 `komorebi_math.langlands.local.heisenberg`

Purpose and source. Finite Heisenberg representations and isotropic selectors. It is an ordinary module in the `langlands` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/langlands/local/heisenberg.py` contains 175 lines and 7,849 bytes. Source SHA-256 begins `489d9922de7922c5`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 1 manifest card: 0 stable, 0 beta, and 1 research. Linked cards: HeisenbergModel. Its `__all__` declaration contains 2 names: `HeisenbergElement`, `HeisenbergModel`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (1): `komorebi_math.langlands.local`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.21 `komorebi_math.langlands.local.symplectic`

Purpose and source. Finite alternating forms, radicals, and dyadic quadratic refinements. It is an ordinary module in the `langlands` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/langlands/local/symplectic.py` contains 174 lines and 7,028 bytes. Source SHA-256 begins `83e286a4dadaf4d2`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: AlternatingForm, QuadraticRefinement. Its `__all__` declaration contains 2 names: `AlternatingForm`, `QuadraticRefinement`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (5): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.deformation.complexes`, `komorebi_math.exceptions`, `komorebi_math.nonlinear.lifting`. Reverse package dependents (3): `komorebi_math.langlands.local`, `komorebi_math.langlands.local.bridge`, `komorebi_math.langlands.local.envelopes`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.22 `komorebi_math.langlands.local.tame`

Purpose and source. Finite tame Frobenius packets and monodromy chains. It is an ordinary module in the `langlands` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/langlands/local/tame.py` contains 277 lines and 9,448 bytes. Source SHA-256 begins `63ba77e6127a5e13`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 2 manifest cards: 0 stable, 0 beta, and 2 research. Linked cards: FrobeniusOrbit, TameWeilPacket. Its `__all__` declaration contains 6 names: `FrobeniusOrbit`, `regular_orbit_count`, `SpecialMonodromyBlock`, `tame_tensor_refinement`, `TameWeilPacket`, `TensorRefinement`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): `komorebi_math._number_theory`, `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package

dependents (1): komorebi_math.langlands.local. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.23 komorebi_math.langlands.ramification

Purpose and source. Finite ramification Clifford tower diagnostics. It is the package initializer for the langlands family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/langlands/ramification/__init__.py contains 38 lines and 806 bytes. Source SHA-256 begins de860a4740cd27ed.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 7 names: FEATURE_KEY, ProjectiveMultiplicityPacket, RamificationCliffordTower, RamificationStage, RamificationTowerReport, require, status.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math._planned, komorebi_math.langlands.ramification.towers, komorebi_math.registry. Reverse package dependents (3): komorebi_math, komorebi_math.langlands, komorebi_math.verify.langlands. Examples (1): ramification_completion.py. Tests or test support files (1): test_langlands_ramification_global_completion.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.19.24 komorebi_math.langlands.ramification.towers

Purpose and source. Finite ramification packet and Clifford tower diagnostics. It is an ordinary module in the langlands family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/langlands/ramification/towers.py contains 188 lines and 8,364 bytes. Source SHA-256 begins 9efdf00432bb3b62.

Surface and ownership. API classification: API-manifested implementation owner. It owns 3 manifest cards: 0 stable, 0 beta, and 3 research. Linked cards: ProjectiveMultiplicityPacket, RamificationCliffordTower, RamificationStage. Its __all__ declaration contains 4 names: ProjectiveMultiplicityPacket, RamificationCliffordTower, RamificationStage, RamificationTowerReport.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (4): komorebi_math._number_theory, komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.langlands.local. Reverse package dependents (1): komorebi_math.langlands.ramification. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.20 Expression: 7 modules

D.2.20.1 komorebi_math.expression

Purpose and source. Research-tier typed finite expression calculus. It is the package initializer for the expression family. The ledger classifies it as an importable package facade outside API manifests. Source src/komorebi_math/expression/__init__.py contains 187 lines and 3,921 bytes. Source SHA-256 begins a4526fb71a56d603.

Surface and ownership. API classification: importable package module outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 83 names: add, affine_substitution, antiderivative, apply, Apply, boundary_functional, check_expression, CheckedExpression, compile_expression, compose, and 73 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): komorebi_math.expression.certification, komorebi_math.expression.engine, komorebi_math.expression.model, komorebi_math.expression.planning, komorebi_math.expression.polynomial, komorebi_math.expression.portable. Reverse package dependents (2): komorebi_math, komorebi_math.verify.expression. Examples (1): block20_typed_expression_worked_example.py. Tests or test support files (1): test_block20_expression_calculus.py. Documentation files with literal module or public-route references (1): PUBLIC_API.md. AST parsing and runtime import both passed in the recorded module audit.

D.2.20.2 komorebi_math.expression.certification

Purpose and source. Sound certificate composition for the research expression calculus. It is an ordinary module in the expression family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/expression/certification.py contains 313 lines and 11,084 bytes. Source SHA-256 begins 4348615486a61a71.

Surface and ownership. API classification: API-manifested implementation owner. It owns 7 manifest cards: 0 stable, 0 beta, and 7 research. Linked cards: compose_certificates, exact_internal_certificate, exactness_strength, ExpressionBinding, NormalForm, RewriteStep, weakest_exactness. Its __all__ declaration contains 7 names: compose_certificates, exact_internal_certificate, exactness_strength, ExpressionBinding, NormalForm, RewriteStep, weakest_exactness.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (2): komorebi_math.expression, komorebi_math.expression.engine. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.20.3 komorebi_math.expression.engine

Purpose and source. Checking, exact normalization, certified rewriting, and execution plans. It is an ordinary module in the expression family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/expression/engine.py contains 1,744 lines and 71,584 bytes. Source SHA-256 begins 5ae39e027b7f9c33.

Surface and ownership. API classification: API-manifested implementation owner. It owns 15 manifest cards: 0 stable, 0 beta, and 15 research. Linked cards: check_expression, CheckedExpression, compile_expression, EquivalenceResult, equivalent, evaluate_expression, exact_binding, execute_plan, ExpressionPlan, ExpressionResult, and 5 more in the machine-readable ledger. Its __all__ declaration contains 15 names: check_expression, CheckedExpression, compile_expression, EquivalenceResult, equivalent, evaluate_expression, exact_binding, execute_plan, ExpressionPlan, ExpressionResult, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (8): komorebi_math.certificates, komorebi_math.coordinates.exact, komorebi_math.exceptions, komorebi_math.expression.certification, komorebi_math.expression.model, komorebi_math.expression.planning, and 2 more in the machine-readable ledger. Reverse package dependents (2): komorebi_math.expression, komorebi_math.expression.portable. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.20.4 komorebi_math.expression.model

Purpose and source. Typed immutable expressions for finite exact rational computations. It is an ordinary module in the expression family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/expression/model.py contains 712 lines and 24,960 bytes. Source SHA-256 begins e01883acc993da14.

Surface and ownership. API classification: API-manifested implementation owner. It owns 28 manifest cards: 0 stable, 0 beta, and 28 research. Linked cards: add, Apply, apply, Compose, compose, exact_map, exact_value, ExactMapLiteral, ExactValueLiteral, Expression, and 18 more in the machine-readable ledger. Its __all__ declaration contains 30 names: add, Apply, apply, compose, Compose, CoordinateSpace, exact_map, exact_value, ExactMapLiteral, ExactValueLiteral, and 20 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.coordinates.exact, komorebi_math.exceptions. Reverse package dependents (4): komorebi_math.expression, komorebi_math.expression.engine, komorebi_math.expression.polynomial, komorebi_math.expression.portable. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.20.5 komorebi_math.expression.planning

Purpose and source. Exact dense matrix-chain planning independent of expression evaluation. It is an ordinary module in the expression family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/expression/planning.py contains 400 lines and 15,157 bytes. Source SHA-256 begins cfa5341a696cabed.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: matrix_chain_multiply, matrix_chain_parenthesization, matrix_chain_plan, MatrixChainPlan, MatrixChainTree. Its __all__ declaration contains 5 names: matrix_chain_multiply, matrix_chain_parenthesization, matrix_chain_plan, MatrixChainPlan, MatrixChainTree.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.coordinates.exact, komorebi_math.exceptions. Reverse package dependents (2): komorebi_math.expression, komorebi_math.expression.engine. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.20.6 komorebi_math.expression.polynomial

Purpose and source. Replayable exact polynomial primitives for the expression calculus. It is an ordinary module in the expression family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/expression/polynomial.py contains 624 lines and 21,239 bytes. Source SHA-256 begins 73a4a594e4c0f26c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 15 manifest cards: 0 stable, 0 beta, and 15 research. Linked cards: affine_substitution, antiderivative, boundary_functional, constant_injection, coordinate_change, derivative, evaluation, finite_difference, interval_integration, PolynomialPrimitive, and 5 more in the machine-readable ledger. Its __all__ declaration contains 15 names: affine_substitution, antiderivative, boundary_functional, constant_injection, coordinate_change, derivative, evaluation, finite_difference, interval_integration, PolynomialPrimitive, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.certificates, komorebi_math.coordinates.exact, komorebi_math.exceptions, komorebi_math.expression.model. Reverse package dependents (3): komorebi_math.expression, komorebi_math.expression.engine, komorebi_math.expression.portable. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.20.7 komorebi_math.expression.portable

Purpose and source. Strict portable JSON for finite typed expressions. It is an ordinary module in the expression family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/expression/portable.py contains 1,025 lines and 36,065 bytes. Source SHA-256 begins 366c25d81842e91c.

Surface and ownership. API classification: API-manifested implementation owner. It owns 7 manifest cards: 0 stable, 0 beta, and 7 research. Linked cards: expression_digest, expression_from_dict, expression_from_json, expression_to_dict, expression_to_json, type_from_dict, type_to_dict. Its __all__ declaration contains 11 names: expression_digest, expression_from_dict, expression_from_json, EXPRESSION_NODE_VERSION, EXPRESSION_SCHEMA, EXPRESSION_SCHEMA_VERSION, expression_to_dict, expression_to_json, EXPRESSION_TYPE_VERSION, type_from_dict, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): komorebi_math.exceptions, komorebi_math.expression.engine, komorebi_math.expression.model, komorebi_math.expression.polynomial. Reverse package dependents (2): komorebi_math.expression, komorebi_math.expression.engine. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21 Export: 8 modules

D.2.21.1 komorebi_math.export

Purpose and source. Portable data, report, LaTeX, and PDF export tools. It is the package initializer for the export family. The ledger classifies it as a canonical API namespace facade. Source src/komorebi_math/export/__init__.py contains 131 lines and 2,743 bytes. Source SHA-256 begins 46407a9f8b1ddb00.

Surface and ownership. API classification: canonical public namespace without implementation ownership. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 58 names: available_export_formats, available_latex_engines, certificate_document, CodeBlock, compile_latex, document_from_data, DocumentMetadata, dumps_portable, Equation, export_adapters, and 48 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): komorebi_math.export.latex, komorebi_math.export.model, komorebi_math.export.persistence, komorebi_math.export.renderers, komorebi_math.export.report, komorebi_math.export.serialization, and 1 more in the machine-readable ledger. Reverse package dependents (8): komorebi_math, komorebi_math.cli.main, komorebi_math.stable, komorebi_math.verify.coordinates, komorebi_math.verify.export, komorebi_math.verify.generating, and 2 more in the machine-readable ledger. Examples (5): block21_public_capability_tour.py, custom_generating_functions.py, export_reports.py, portable_nonlinear_state.py, scalable_nonlinear.py. Tests or test support files (16): test_block10_execution_persistence.py, test_block11_streaming_migrations.py, test_block15_persistence.py, test_block15_polyphase_refinement.py, test_block15_stable_api.py, and 11 more in the machine-readable ledger. Documentation files with literal module or public-route references (8): API_COMPATIBILITY_0.11.md, API_COMPATIBILITY_0.12.md, API_COMPATIBILITY_0.13.md, BLOCK_10_RELEASE.md, EXPORT_AND_LATEX.md, and 3 more in the machine-readable ledger. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.2 komorebi_math.export.latex

Purpose and source. LaTeX compilation with explicit engine discovery. It is an ordinary module in the export family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/export/latex.py contains 267 lines and 8,921 bytes. Source SHA-256 begins 6732665ea6282003.

Surface and ownership. API classification: API-manifested implementation owner. It owns 10 manifest cards: 0 stable, 0 beta, and 10 research. Linked cards: available_latex_engines, compile_latex, LatexCompileOptions, LatexEngine, available_latex_engines, compile_latex, LatexCompilation, LatexCompileOptions, LatexEngine, resolve_latex_engine. Its __all__ declaration contains 6 names: available_latex_engines, compile_latex, LatexCompilation, LatexCompileOptions, LatexEngine, resolve_latex_engine.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (5): komorebi_math, komorebi_math.cli.main, komorebi_math.export, komorebi_math.export.writers, komorebi_math.verify.export. Examples (1): export_reports.py. Tests or test support files (2): test_export_cli.py, test_export_files.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.3 komorebi_math.export.model

Purpose and source. Document objects for portable mathematical exports. It is an ordinary module in the export family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/export/model.py contains 244 lines and 6,917 bytes. Source SHA-256 begins 14821695790ebcf9.

Surface and ownership. API classification: API-manifested implementation owner. It owns 18 manifest cards: 4 stable, 0 beta, and 14 research. Linked cards: DocumentMetadata, Equation, MathDocument, Paragraph, DocumentMetadata, Equation, MathDocument, Table, CodeBlock, DocumentMetadata, and 8 more in the machine-readable ledger. Its __all__ declaration contains 11 names: CodeBlock, DocumentBlock, DocumentMetadata, Equation, Figure, Heading, ListBlock, MathDocument, Paragraph, RawLatex, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.exceptions`. Reverse package dependents (8): `komorebi_math`, `komorebi_math.export`, `komorebi_math.export.renderers`, `komorebi_math.export.report`, `komorebi_math.export.writers`, `komorebi_math.stable`, and 2 more in the machine-readable ledger. Examples (1): `export_reports.py`. Tests or test support files (2): `test_export_files.py`, `test_export_renderers.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.4 `komorebi_math.export.persistence`

Purpose and source. Versioned, digest-checked persistence for finite Komorebi objects. It is an ordinary module in the `export` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/export/persistence.py` contains 887 lines and 32,742 bytes. Source SHA-256 begins `0044e9c7eb95677d`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 48 manifest cards: 11 stable, 13 beta, and 24 research. Linked cards: dumps_portable, from_portable_data, load_portable, loads_portable, portable_codecs, portable_digest, portable_migrations, PortableCodec, PortableMigration, save_portable, and 38 more in the machine-readable ledger. Its `__all__` declaration contains 15 names: `dumps_portable`, `from_portable_data`, `load_portable`, `loads_portable`, `portable_codecs`, `portable_digest`, `portable_migrations`, `PORTABLE_SCHEMA`, `PORTABLE_SCHEMA_VERSION`, `PortableCodec`, and 5 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (13): `komorebi_math._version`, `komorebi_math.certificates`, `komorebi_math.coordinates.portable`, `komorebi_math.deformation.forests`, `komorebi_math.exceptions`, `komorebi_math.generating.portable`, and 7 more in the machine-readable ledger. Reverse package dependents (19): `komorebi_math`, `komorebi_math.beta`, `komorebi_math.coordinates.portable`, `komorebi_math.export`, `komorebi_math.generating.portable`, `komorebi_math.golden`, and 13 more in the machine-readable ledger. Examples (5): `block16_analysis_synthesis.py`, `block21_public_capability_tour.py`, `custom_generating_functions.py`, `portable_nonlinear_state.py`, `scalable_nonlinear.py`. Tests or test support files (12): `test_block10_execution_persistence.py`, `test_block11_streaming_migrations.py`, `test_block15_persistence.py`, `test_block15_polyphase_refinement.py`, `test_block15_stable_api.py`, and 7 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.5 `komorebi_math.export.renderers`

Purpose and source. Text, Markdown, HTML, and LaTeX renderers. It is an ordinary module in the `export` family. The ledger classifies it as a public implementation owner. Source `src/komorebi_math/export/renderers.py` contains 402 lines and 16,487 bytes. Source SHA-256 begins `1a86b12145e02c30`.

Surface and ownership. API classification: API-manifested implementation owner. It owns 12 manifest cards: 2 stable, 0 beta, and 10 research. Linked cards: render_latex, render_markdown, LatexRenderOptions, render_latex, HtmlRenderOptions, latex_escape, latex_label, LatexRenderOptions, render_html, render_latex, and 2 more in the machine-readable ledger. Its `__all__` declaration contains 8 names: `HtmlRenderOptions`, `latex_escape`, `latex_label`, `LatexRenderOptions`, `render_html`, `render_latex`, `render_markdown`, `render_text`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.export.model`. Reverse package dependents (7): `komorebi_math`, `komorebi_math.cli.main`, `komorebi_math.export`, `komorebi_math.export.writers`, `komorebi_math.stable`, `komorebi_math.stable_semantics`, and 1 more in the machine-readable ledger. Examples (0): none. Tests or test support files (1): `test_export_renderers.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.6 komorebi_math.export.report

Purpose and source. Adapters that turn mathematical values into readable documents. It is an ordinary module in the export family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/export/report.py contains 142 lines and 5,310 bytes. Source SHA-256 begins f303c23f5f9c027f.

Surface and ownership. API classification: API-manifested implementation owner. It owns 5 manifest cards: 0 stable, 0 beta, and 5 research. Linked cards: document_from_data, sequence_document, certificate_document, document_from_data, sequence_document. Its __all__ declaration contains 3 names: certificate_document, document_from_data, sequence_document.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.certificates, komorebi_math.export.model, komorebi_math.export.serialization. Reverse package dependents (4): komorebi_math, komorebi_math.cli.main, komorebi_math.export, komorebi_math.export.writers. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.7 komorebi_math.export.serialization

Purpose and source. Normalization helpers for portable data export. It is an ordinary module in the export family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/export/serialization.py contains 351 lines and 12,158 bytes. Source SHA-256 begins 20d4f7cf7754519d.

Surface and ownership. API classification: API-manifested implementation owner. It owns 8 manifest cards: 0 stable, 0 beta, and 8 research. Linked cards: from_serializable, to_serializable, export_adapters, Exportable, from_serializable, register_export_adapter, table_rows, to_serializable. Its __all__ declaration contains 6 names: export_adapters, Exportable, from_serializable, register_export_adapter, table_rows, to_serializable.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.exceptions. Reverse package dependents (6): komorebi_math, komorebi_math.cli.main, komorebi_math.export, komorebi_math.export.report, komorebi_math.export.writers, komorebi_math.verify.export. Examples (0): none. Tests or test support files (3): test_block10_execution_persistence.py, test_export_serialization.py, test_nonlinear_snapshots_persistence.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.21.8 komorebi_math.export.writers

Purpose and source. File writers for data, reports, LaTeX, and compiled PDFs. It is an ordinary module in the export family. The ledger classifies it as a public implementation owner. Source src/komorebi_math/export/writers.py contains 518 lines and 18,038 bytes. Source SHA-256 begins 4ac13bea553cd032.

Surface and ownership. API classification: API-manifested implementation owner. It owns 19 manifest cards: 0 stable, 0 beta, and 19 research. Linked cards: available_export_formats, export_bundle, export_data, export_document, export_many, ExportBundleResult, ExportFormat, ExportOptions, ExportResult, available_export_formats, and 9 more in the machine-readable ledger. Its __all__ declaration contains 10 names: available_export_formats, export_bundle, export_data, export_document, export_many, ExportBundleResult, ExportFormat, ExportOptions, ExportResult, infer_export_format.

Dependencies and evidence. Direct dependency profile: optional yaml extra, required NumPy dependency. Direct package dependencies (7): komorebi_math.certificates, komorebi_math.exceptions, komorebi_math.export.latex, komorebi_math.export.model, komorebi_math.export.renderers, komorebi_math.export.report, and 1 more in the machine-readable ledger. Reverse package dependents (4): komorebi_math, komorebi_math.cli.main, komorebi_math.export, komorebi_math.verify.export. Examples (1): export_reports.py. Tests or test support files (1): test_export_files.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.22 Extensions: 3 modules

D.2.22.1 `komorebi_math.extensions`

Purpose and source. Extension API and runtime discovery. It is the package initializer for the `extensions` family. The ledger classifies it as an extension infrastructure module. Source `src/komorebi_math/extensions/__init__.py` contains 6 lines and 254 bytes. Source SHA-256 begins `f58b0afe8ae4a746`.

Surface and ownership. API classification: extension infrastructure outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 4 names: `discover_extensions`, `ENTRY_POINT_GROUP`, `ExtensionLoadResult`, `ExtensionSpec`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math.extensions.api`, `komorebi_math.extensions.discovery`. Reverse package dependents (1): `komorebi_math.cli.main`. Examples (0): none. Tests or test support files (1): `test_unified_extensions_cli.py`. Documentation files with literal module or public-route references (2): `EXTENSION_API.md`, `PUBLIC_API.md`. AST parsing and runtime import both passed in the recorded module audit.

D.2.22.2 `komorebi_math.extensions.api`

Purpose and source. Public extension contract. It is an ordinary module in the `extensions` family. The ledger classifies it as an extension infrastructure module. Source `src/komorebi_math/extensions/api.py` contains 26 lines and 687 bytes. Source SHA-256 begins `e0a5f52cd0e4dbd4`.

Surface and ownership. API classification: extension infrastructure outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: `ExtensionSpec`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (2): `komorebi_math.extensions`, `komorebi_math.extensions.discovery`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.22.3 `komorebi_math.extensions.discovery`

Purpose and source. Extension discovery through standard Python entry points. It is an ordinary module in the `extensions` family. The ledger classifies it as an extension infrastructure module. Source `src/komorebi_math/extensions/discovery.py` contains 41 lines and 1,475 bytes. Source SHA-256 begins `93b3ea91e482d33d`.

Surface and ownership. API classification: extension infrastructure outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 2 top-level public definitions: `discover_extensions`, `ExtensionLoadResult`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): `komorebi_math.extensions.api`. Reverse package dependents (1): `komorebi_math.extensions`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.23 Cli: 3 modules

D.2.23.1 komorebi_math.cli

Purpose and source. Command-line package. It is the package initializer for the cli family. The ledger classifies it as a command line implementation module. Source src/komorebi_math/cli/__init__.py contains 1 lines and 28 bytes. Source SHA-256 begins d79725da2dfaf0df.

Surface and ownership. API classification: CLI implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found no top-level public definitions.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (0): none. Examples (8): Test-KomorebiBlock10.ps1, Test-KomorebiBlock11.ps1, Test-KomorebiBlock12.ps1, Test-KomorebiBlock13.ps1, Test-KomorebiBlock14.ps1, and 3 more in the machine-readable ledger. Tests or test support files (10): test_block10_cli.py, test_block11_cli.py, test_block12_cli_api.py, test_block13_cli_api.py, test_block14_cli_api.py, and 5 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.23.2 komorebi_math.cli.contracts

Purpose and source. Frozen command-line names covered by the release contract. It is an ordinary module in the cli family. The ledger classifies it as a command line implementation module. Source src/komorebi_math/cli/contracts.py contains 59 lines and 1,051 bytes. Source SHA-256 begins 39011c0addae62b5.

Surface and ownership. API classification: CLI implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 2 names: API_CONTRACT_MODES, VERIFICATION_SUITE_NAMES.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (0): none. Reverse package dependents (2): komorebi_math.cli.main, komorebi_math.release.contract. Examples (0): none. Tests or test support files (1): test_block16_release_contract.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.23.3 komorebi_math.cli.main

Purpose and source. Command-line interface for package inspection and verification. It is an ordinary module in the cli family. The ledger classifies it as a command line implementation module. Source src/komorebi_math/cli/main.py contains 1,651 lines and 67,103 bytes. Source SHA-256 begins a61a4e5d81a838e7.

Surface and ownership. API classification: CLI implementation outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 48 top-level public definitions: build_parser, command_api_check, command_api_snapshot, command_completion, command_coordinates_basis, command_coordinates_catalog, command_coordinates_combinatorial, command_coordinates_euler_fibonacci, command_coordinates_formal, command_coordinates_model, and 38 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (39): komorebi_math.arithmetic, komorebi_math.backends, komorebi_math.cli.contracts, komorebi_math.compatibility, komorebi_math.coordinates, komorebi_math.coordinates.basis, and 33 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.__main__. Examples (8): Test-KomorebiBlock10.ps1, Test-KomorebiBlock11.ps1, Test-KomorebiBlock12.ps1, Test-KomorebiBlock13.ps1, Test-KomorebiBlock14.ps1, and 3 more in the machine-readable ledger. Tests or test support files (9): test_block10_cli.py, test_block11_cli.py, test_block12_cli_api.py, test_block13_cli_api.py, test_block14_cli_api.py, and 4 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24 Release: 8 modules

D.2.24.1 `komorebi_math.release`

Purpose and source. Release, upgrade, evidence, documentation, readiness, and GPU gates. It is the package initializer for the `release` family. The ledger classifies it as a release infrastructure module. Source `src/komorebi_math/release/__init__.py` contains 12 lines and 670 bytes. Source SHA-256 begins `93d7ade753bb79de`.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 41 names: `ApiTier`, `BetaReadinessReport`, `check_beta_readiness`, `check_release_contract`, `check_stable_documentation`, `check_upgrade_contract`, `check_validation_evidence`, `ContractArtifact`, `create_stable_documentation_contract`, `current_runtime_record`, and 31 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (6): `komorebi_math.release.contract`, `komorebi_math.release.documentation`, `komorebi_math.release.evidence`, `komorebi_math.release.gpu`, `komorebi_math.release.readiness`, `komorebi_math.release.upgrade`. Reverse package dependents (4): `komorebi_math.cli.main`, `komorebi_math.qualification`, `komorebi_math.verify.beta`, `komorebi_math.verify.release`. Examples (0): none. Tests or test support files (6): `test_block16_gpu_qualification.py`, `test_block16_release_contract.py`, `test_block17_documentation.py`, `test_block17_evidence.py`, `test_block17_release_contract.py`, and 1 more in the machine-readable ledger. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.2 `komorebi_math.release._gpu_worker`

Purpose and source. Private isolated worker for `komorebi_math.release.gpu`. It is an ordinary module in the `release` family. The ledger classifies it as an internal support module. Source `src/komorebi_math/release/_gpu_worker.py` contains 112 lines and 5,194 bytes. Source SHA-256 begins `45d51b0da5eeadce`.

Surface and ownership. API classification: internal by module name. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: `main`.

Dependencies and evidence. Direct dependency profile: optional CuPy accelerator outside the declared project extras, optional `torch` or `autodiff` extra, required NumPy dependency. Direct package dependencies (1): `komorebi_math.algorithms`. Reverse package dependents (0): none. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.3 `komorebi_math.release.contract`

Purpose and source. Machine-readable contract for the reference Komorebi Math beta. It is an ordinary module in the `release` family. The ledger classifies it as a release infrastructure module. Source `src/komorebi_math/release/contract.py` contains 94 lines and 10,362 bytes. Source SHA-256 begins `80f205ddc875538f`.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 11 names: `ApiTier`, `check_release_contract`, `ContractArtifact`, `current_runtime_record`, `DEFAULT_RELEASE_CONTRACT`, `load_release_contract`, `QualificationCheck`, `RELEASE_CONTRACT_SCHEMA`, `RELEASE_CONTRACT_SCHEMA_VERSION`, `ReleaseContract`, and 1 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (11): `komorebi_math._version`, `komorebi_math.certificates`, `komorebi_math.cli.contracts`, `komorebi_math.compatibility`, `komorebi_math.exceptions`, `komorebi_math.persistence_contract`, and 5 more in the machine-readable ledger. Reverse package dependents (2): `komorebi_math.release`, `komorebi_math.release.readiness`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.4 `komorebi_math.release.documentation`

Purpose and source. Exact documentation coverage for the frozen stable namespace. It is an ordinary module in the `release` family. The ledger classifies it as a release infrastructure module. Source `src/komorebi_math/release/documentation.py` contains 342 lines and 12,229 bytes. Source SHA-256 begins `9158244b43886cd5`.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 9 names: `check_stable_documentation`, `create_stable_documentation_contract`, `DEFAULT_STABLE_DOCUMENTATION`, `load_stable_documentation`, `STABLE_DOCUMENTATION_SCHEMA`, `STABLE_DOCUMENTATION_SCHEMA_VERSION`, `StableDocumentationContract`, `StableDocumentationEntry`, `StableDocumentationReport`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math._version`, `komorebi_math.certificates`, `komorebi_math.compatibility`, `komorebi_math.exceptions`. Reverse package dependents (3): `komorebi_math.release`, `komorebi_math.release.contract`, `komorebi_math.release.readiness`. Examples (0): none. Tests or test support files (1): `test_block17_documentation.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.5 `komorebi_math.release.evidence`

Purpose and source. Digest-checked executed-platform evidence for the Komorebi Math 1.0 beta. It is an ordinary module in the `release` family. The ledger classifies it as a release infrastructure module. Source `src/komorebi_math/release/evidence.py` contains 341 lines and 12,955 bytes. Source SHA-256 begins `c471af87d4ef017e`.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 8 names: `check_validation_evidence`, `DEFAULT_VALIDATION_EVIDENCE`, `load_validation_evidence`, `VALIDATION_EVIDENCE_SCHEMA`, `VALIDATION_EVIDENCE_SCHEMA_VERSION`, `ValidationEvidence`, `ValidationEvidenceRecord`, `ValidationEvidenceReport`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (4): `komorebi_math._version`, `komorebi_math.certificates`, `komorebi_math.exceptions`, `komorebi_math.release.upgrade`. Reverse package dependents (3): `komorebi_math.release`, `komorebi_math.release.contract`, `komorebi_math.release.readiness`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.6 `komorebi_math.release.gpu`

Purpose and source. Crash-isolated CUDA qualification for optional PyTorch and CuPy paths. It is an ordinary module in the `release` family. The ledger classifies it as a release infrastructure module. Source `src/komorebi_math/release/gpu.py` contains 178 lines and 5,658 bytes. Source SHA-256 begins `4cbc2f52cec7a18f`.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 3 names: `GpuBackendResult`, `GpuQualificationReport`, `qualify_gpu`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): `komorebi_math.certificates`, `komorebi_math.exceptions`. Reverse package dependents (2): `komorebi_math.release`, `komorebi_math.release.readiness`. Examples (0): none. Tests or test support files (1): `test_block16_gpu_qualification.py`. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.7 komorebi_math.release.readiness

Purpose and source. Aggregate public-beta and release-candidate readiness gates. It is an ordinary module in the release family. The ledger classifies it as a release infrastructure module. Source src/komorebi_math/release/readiness.py contains 44 lines and 3,702 bytes. Source SHA-256 begins 4b1c4c219082e6d0.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 2 names: BetaReadinessReport, check_beta_readiness.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (13): komorebi_math._version, komorebi_math.api, komorebi_math.api.v1, komorebi_math.certificates, komorebi_math.release.contract, komorebi_math.release.documentation, and 7 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.release. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.24.8 komorebi_math.release.upgrade

Purpose and source. Cross-version upgrade contract for the Komorebi Math 1.0 line. It is an ordinary module in the release family. The ledger classifies it as a release infrastructure module. Source src/komorebi_math/release/upgrade.py contains 137 lines and 9,819 bytes. Source SHA-256 begins 8fce6479bd8875e4.

Surface and ownership. API classification: release tooling outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 8 names: check_upgrade_contract, DEFAULT_UPGRADE_CONTRACT, load_upgrade_contract, UpgradeArtifact, UpgradeCheck, UpgradeContract, UpgradeContractReport, UpgradeFixture.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): komorebi_math._version, komorebi_math.certificates, komorebi_math.compatibility, komorebi_math.exceptions, komorebi_math.export.persistence, komorebi_math.persistence_contract, and 1 more in the machine-readable ledger. Reverse package dependents (4): komorebi_math.release, komorebi_math.release.contract, komorebi_math.release.evidence, komorebi_math.release.readiness. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25 Verify: 28 modules

D.2.25.1 komorebi_math.verify

Purpose and source. Installed package verification entry points. It is the package initializer for the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/__init__.py contains 249 lines and 8,639 bytes. Source SHA-256 begins 569fa314a0d4a8d7.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 56 names: run_advanced_nonlinear_verification, run_algorithms_verification, run_analytic_verification, run_arithmetic_verification, run_beta_readiness_verification, run_block10_verification, run_block11_verification, run_block12_verification, run_block13_verification, run_block14_verification, and 46 more in the machine-readable ledger.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (26): komorebi_math.verify.algorithms, komorebi_math.verify.analytic, komorebi_math.verify.arithmetic, komorebi_math.verify.beta, komorebi_math.verify.coordinates, komorebi_math.verify.core, and 20 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.cli.main. Examples (0): none. Tests or test support files (3): test_block16_release_qualification.py, test_block17_release_contract.py, test_unified_extensions_cli.py. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.2 komorebi_math.verify.algorithms

Purpose and source. Installed package verification for structured algorithms. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/algorithms.py contains 150 lines and 4,882 bytes. Source SHA-256 begins b9ca065d0d4af8a4.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: run_algorithms_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.algorithms, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.3 komorebi_math.verify.analytic

Purpose and source. Installed verification for cyclic analytic functions. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/analytic.py contains 104 lines and 3,721 bytes. Source SHA-256 begins d2ccc2ee0e4ae07a.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_analytic_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.analytic, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.4 komorebi_math.verify.arithmetic

Purpose and source. Installed verification for local arithmetic packets. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/arithmetic.py contains 101 lines and 3,975 bytes. Source SHA-256 begins 7f4960cd813a8e2a.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_arithmetic_verification.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.arithmetic, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.5 komorebi_math.verify.beta

Purpose and source. Installed verification for the Komorebi Math 1.0 public beta. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/beta.py contains 8 lines and 1,036 bytes. Source SHA-256 begins f1579f4095f62875.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 4 names: run_beta_readiness_verification, run_documentation_verification, run_evidence_verification, run_upgrade_verification.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.release, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.6 komorebi_math.verify.coordinates

Purpose and source. Installed-package verification for the exact coordinate calculus. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/coordinates.py contains 447 lines and 19,322 bytes. Source SHA-256 begins 82e37ae57211e3d6.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_coordinates_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (27): komorebi_math.coordinates, komorebi_math.coordinates.affine, komorebi_math.coordinates.basis, komorebi_math.coordinates.budget, komorebi_math.coordinates.calculus, komorebi_math.coordinates.classical, and 21 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.7 komorebi_math.verify.core

Purpose and source. Lightweight installed package verification for the finite core. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/core.py contains 144 lines and 4,892 bytes. Source SHA-256 begins d673945ade70d3cb.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 3 top-level public definitions: run_core_verification, VerificationCheck, VerificationReport.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): komorebi_math.certificates, komorebi_math.core. Reverse package dependents (26): komorebi_math.verify, komorebi_math.verify.algorithms, komorebi_math.verify.analytic, komorebi_math.verify.arithmetic, komorebi_math.verify.beta, komorebi_math.verify.coordinates, and 20 more in the machine-readable ledger. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.8 komorebi_math.verify.deformation

Purpose and source. Installed verification for finite deformation and support models. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/deformation.py contains 75 lines and 2,650 bytes. Source SHA-256 begins f5a9e5a74933e080.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_deformation_verification.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (2): komorebi_math.deformation, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.9 komorebi_math.verify.dsp

Purpose and source. Installed-package verification for the DSP implementation. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/dsp.py contains 172 lines and 6,115 bytes. Source SHA-256 begins 688c3f4d5b39eb23.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_dsp_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (12): `komorebi_math.signals`, `komorebi_math.signals.adaptive`, `komorebi_math.signals.denoise`, `komorebi_math.signals.fft_convolution`, `komorebi_math.signals.filtering`, `komorebi_math.signals.recursive`, and 6 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.10 `komorebi_math.verify.dynamics`

Purpose and source. Installed package verification for semigroups, probability, and memory. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/dynamics.py` contains 142 lines and 5,020 bytes. Source SHA-256 begins `e8f740da54c4c4be`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 1 name: `run_dynamics_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (2): `komorebi_math.dynamics`, `komorebi_math.verify.core`. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.11 `komorebi_math.verify.export`

Purpose and source. Installed verification suite for portable exports and LaTeX output. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/export.py` contains 118 lines and 4,497 bytes. Source SHA-256 begins `9d6757c71e0df993`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 1 name: `run_export_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (7): `komorebi_math.export`, `komorebi_math.export.latex`, `komorebi_math.export.model`, `komorebi_math.export.renderers`, `komorebi_math.export.serialization`, `komorebi_math.export.writers`, and 1 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.12 `komorebi_math.verify.expression`

Purpose and source. Installed verification for the finite typed expression calculus. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/expression.py` contains 559 lines and 20,753 bytes. Source SHA-256 begins `fee8884d61def5d8`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 1 name: `run_expression_verification`.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): `komorebi_math.certificates`, `komorebi_math.coordinates`, `komorebi_math.coordinates.exact`, `komorebi_math.coordinates.polynomials`, `komorebi_math.exceptions`, `komorebi_math.expression`, and 1 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.13 komorebi_math.verify.frame_algebra

Purpose and source. Installed verification for redundant-frame algebra. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/frame_algebra.py contains 125 lines and 4,628 bytes. Source SHA-256 begins 017efd3c54ca263c.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_frame_algebra_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): komorebi_math.coordinates, komorebi_math.coordinates.analysis_synthesis, komorebi_math.coordinates.exact, komorebi_math.coordinates.frame_algebra, komorebi_math.exceptions, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.14 komorebi_math.verify.generating

Purpose and source. Installed-package verification for normalized generating functions. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/generating.py contains 199 lines and 7,112 bytes. Source SHA-256 begins d02a650e9c627111.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_generating_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (15): komorebi_math.export, komorebi_math.export.persistence, komorebi_math.generating, komorebi_math.generating.adapters, komorebi_math.generating.basis, komorebi_math.generating.bell, and 9 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.15 komorebi_math.verify.gpu

Purpose and source. Crash-isolated hardware-backed CUDA verification. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/gpu.py contains 42 lines and 1,405 bytes. Source SHA-256 begins e5234f735f8cfc2a.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_gpu_verification.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.qualification, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.16 komorebi_math.verify.hardening

Purpose and source. Compatibility import for the scalable nonlinear verification suite. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/hardening.py contains 5 lines and 203 bytes. Source SHA-256 begins 5bd44d51e6397c7a.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_scalable_nonlinear_verification.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (1): komorebi_math.verify.scalable_nonlinear. Reverse

package dependents (0): none. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.17 `komorebi_math.verify.integration`

Purpose and source. Installed verification for finite measure integration. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/integration.py` contains 255 lines and 10,325 bytes. Source SHA-256 begins `43fa1d21f1e086af`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 1 name: `run_integration_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (8): `komorebi_math.certificates`, `komorebi_math.coordinates`, `komorebi_math.coordinates.analysis_synthesis`, `komorebi_math.coordinates.classical`, `komorebi_math.coordinates.polynomials`, `komorebi_math.exceptions`, and 2 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.18 `komorebi_math.verify.langlands`

Purpose and source. Installed verification for finite local, finite image, and completion models. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/langlands.py` contains 168 lines and 6,308 bytes. Source SHA-256 begins `b2a1616fec75cf0d`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 4 names: `run_langlands_completion_verification`, `run_langlands_finite_image_verification`, `run_langlands_local_verification`, `run_langlands_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (6): `komorebi_math.langlands.completion`, `komorebi_math.langlands.finite_image`, `komorebi_math.langlands.global_`, `komorebi_math.langlands.local`, `komorebi_math.langlands.ramification`, `komorebi_math.verify.core`. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.19 `komorebi_math.verify.nonlinear`

Purpose and source. Installed verification suite for the nonlinear foundation. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/nonlinear.py` contains 92 lines and 3,428 bytes. Source SHA-256 begins `2807f35643e010dd`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 2 names: `run_nonlinear_foundation_verification`, `run_nonlinear_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (9): `komorebi_math.core`, `komorebi_math.nonlinear`, `komorebi_math.nonlinear.coordinates`, `komorebi_math.nonlinear.defects`, `komorebi_math.nonlinear.holonomy`, `komorebi_math.nonlinear.lifting`, and 3 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.20 komorebi_math.verify.nonlinear_advanced

Purpose and source. Installed verification suite for advanced nonlinear calculus. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/nonlinear_advanced.py contains 231 lines and 8,865 bytes. Source SHA-256 begins b8b7d3b65fe11a92.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_advanced_nonlinear_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (14): komorebi_math.certificates, komorebi_math.core, komorebi_math.dynamics._linalg, komorebi_math.nonlinear, komorebi_math.nonlinear.composition, komorebi_math.nonlinear.correction, and 8 more in the machine-readable ledger. Reverse package dependents (2): komorebi_math.verify, komorebi_math.verify.nonlinear. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.21 komorebi_math.verify.quantum

Purpose and source. Installed verification for finite quantum packet calculus. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/quantum.py contains 150 lines and 5,972 bytes. Source SHA-256 begins 8af5b89ad28093b6.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_quantum_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (3): komorebi_math.dynamics, komorebi_math.quantum, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.22 komorebi_math.verify.refinement

Purpose and source. Installed verification suite for refinement and filtered transfer. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/refinement.py contains 88 lines and 3,372 bytes. Source SHA-256 begins e008926e1df92a77.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Static analysis found 1 top-level public definition: run_refinement_verification.

Dependencies and evidence. Direct dependency profile: optional exact extra, required NumPy dependency. Direct package dependencies (3): komorebi_math.core, komorebi_math.refinement, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.23 komorebi_math.verify.release

Purpose and source. Installed release-qualification checks for the path to 1.0. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/release.py contains 95 lines and 3,972 bytes. Source SHA-256 begins 47400964ee98a885.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_release_qualification_verification.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (7): komorebi_math.compatibility, komorebi_math.persistence_contract, komorebi_math.release, komorebi_math.stable, komorebi_math.stable_semantics, komorebi_math.

support, and 1 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.24 komorebi_math.verify.scalable_nonlinear

Purpose and source. Installed verification for the scalable nonlinear runtime. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/scalable_nonlinear.py contains 159 lines and 6,084 bytes. Source SHA-256 begins cccac56a9186bea0.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_scalable_nonlinear_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (15): komorebi_math.certificates, komorebi_math.compatibility, komorebi_math.core, komorebi_math.exceptions, komorebi_math.export, komorebi_math.export.persistence, and 9 more in the machine-readable ledger. Reverse package dependents (2): komorebi_math.verify, komorebi_math.verify.hardening. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.25 komorebi_math.verify.sequences

Purpose and source. Installed verification for lazy exact sequence execution. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/sequences.py contains 77 lines and 2,812 bytes. Source SHA-256 begins 4f7ed71444419308.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_sequences_verification.

Dependencies and evidence. Direct dependency profile: no direct third-party import beyond the standard library and package-local modules. Direct package dependencies (2): komorebi_math.sequences, komorebi_math.verify.core. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.26 komorebi_math.verify.signals

Purpose and source. Installed package verification for the finite signal domain. It is an ordinary module in the verify family. The ledger classifies it as an installed verification module. Source src/komorebi_math/verify/signals.py contains 141 lines and 5,210 bytes. Source SHA-256 begins c981e9878071c41a.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its __all__ declaration contains 1 name: run_signals_verification.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (8): komorebi_math.signals, komorebi_math.signals.filterbanks, komorebi_math.signals.nonlinear, komorebi_math.signals.polyphase, komorebi_math.signals.recovery, komorebi_math.signals.singular_packets, and 2 more in the machine-readable ledger. Reverse package dependents (1): komorebi_math.verify. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.27 `komorebi_math.verify.stabilization`

Purpose and source. Installed verification for polyphase stabilization and 1.0 contracts. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/stabilization.py` contains 175 lines and 6,665 bytes. Source SHA-256 begins `9a969f6fbd408f50`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 2 names: `run_polyphase_stabilization_verification`, `run_stable_contract_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (15): `komorebi_math.api`, `komorebi_math.api.v1`, `komorebi_math.arithmetic`, `komorebi_math.compatibility`, `komorebi_math.core`, `komorebi_math.export.persistence`, and 9 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.2.25.28 `komorebi_math.verify.streaming_beta`

Purpose and source. Installed verification for persistence and compatibility boundaries. It is an ordinary module in the `verify` family. The ledger classifies it as an installed verification module. Source `src/komorebi_math/verify/streaming_beta.py` contains 191 lines and 7,319 bytes. Source SHA-256 begins `fae5f92bedb4f7d8`.

Surface and ownership. API classification: installed verifier outside the API manifests. No stable, beta, or research card names this module as its implementation owner. Its importability or declared names therefore do not create a manifest compatibility promise. Its `__all__` declaration contains 1 name: `run_streaming_beta_verification`.

Dependencies and evidence. Direct dependency profile: required NumPy dependency. Direct package dependencies (13): `komorebi_math.compatibility`, `komorebi_math.core`, `komorebi_math.exceptions`, `komorebi_math.export`, `komorebi_math.export.persistence`, `komorebi_math.golden`, and 7 more in the machine-readable ledger. Reverse package dependents (1): `komorebi_math.verify`. Examples (0): none. Tests or test support files (0): none. Documentation files with literal module or public-route references (0): none. AST parsing and runtime import both passed in the recorded module audit.

D.3 External implementation-owner rows

Five manifest owner strings resolve to Python or typing support modules rather than Komorebi source files. They own data aliases, protocols, paths, or runtime types that are exposed through Komorebi namespaces. These rows close the implementation-owner crosswalk without presenting the standard library as Komorebi implementation code.

D.3.1 `builtins`

Owner scope. External Python or typing support owner. It owns 48 cards: 9 stable, 10 beta, and 29 research. Linked cards: **version**, PORTABLE_CODEC_CONTRACT_SCHEMA, PORTABLE_CODEC_CONTRACT_SCHEMA_VERSION, PORTABLE_SCHEMA, PORTABLE_SCHEMA_VERSION, STABLE_API_STABILITY_LEVEL, STABLE_PUBLIC_NAMESPACES, STABLE_SEMANTICS_SCHEMA, STABLE_SEMANTICS_SCHEMA_VERSION, **version**, BEHAVIORAL_GOLDEN_SCHEMA, BEHAVIORAL_GOLDEN_SCHEMA_VERSION, and 36 more in the machine-readable ledger.

Evidence. Examples (1): `block21_public_capability_tour.py`. Tests or support files (4): `test_block15_stable_api.py`, `test_block16_analysis_synthesis.py`, `test_block16_release_contract.py`, `test_block19_integration.py`. Documentation files with literal public-route references (0): none. No Komorebi source path or source digest is assigned to this row.

D.3.2 `collections.abc`

Owner scope. External Python or typing support owner. It owns 3 cards: 0 stable, 0 beta, and 3 research. Linked cards: MultilinearOperation, DirectionalDerivative, MultilinearOperation.

Evidence. Examples (0): none. Tests or support files (0): none. Documentation files with literal public-route references (0): none. No Komorebi source path or source digest is assigned to this row.

D.3.3 `pathlib`

Owner scope. External Python or typing support owner. It owns 4 cards: 2 stable, 0 beta, and 2 research. Linked cards: DEFAULT_PORTABLE_CODEC_CONTRACT, DEFAULT_STABLE_SEMANTICS_FIXTURE, DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE, DEFAULT_BETA_API_MANIFEST.

Evidence. Examples (0): none. Tests or support files (0): none. Documentation files with literal public-route references (0): none. No Komorebi source path or source digest is assigned to this row.

D.3.4 `types`

Owner scope. External Python or typing support owner. It owns 6 cards: 1 stable, 0 beta, and 5 research. Linked cards: PolyphaseCoordinateRecord, CoordinateSpace, ExpressionType, Scalar, PacketLabel, PacketPath.

Evidence. Examples (0): none. Tests or support files (1): `test_block15_stable_api.py`. Documentation files with literal public-route references (0): none. No Komorebi source path or source digest is assigned to this row.

D.3.5 `typing`

Owner scope. External Python or typing support owner. It owns 16 cards: 0 stable, 0 beta, and 16 research. Linked cards: RecurrenceLike, Variance, AdaptiveMethod, BiquadKind, BoundaryMode, ConvolutionMode, DetrendMode, FIRKind, FIRMode, SpectralAverage, SpectralScaling, SpectrogramScaling, and 4 more in the machine-readable ledger.

Evidence. Examples (0): none. Tests or support files (0): none. Documentation files with literal public-route references (0): none. No Komorebi source path or source digest is assigned to this row.

D.4 Machine-readable crosswalk and closure

The machine-readable ledger contains the complete arrays abbreviated by the printed cards. `Block36_Module_Reference_Ledger.json` is the canonical module inventory. `Block36_Module_Reference_Ledger.csv` provides one row per package module. The family summary, external-owner crosswalk, internal dependency edge list, and evidence edge list are emitted as separate CSV files.

Crosswalk	Rows
Package module cards	300
External owner rows	5
Direct package dependency edges	1591
Module to example edges	268
Module to test or support-file edges	668
Module to documentation edges	165

Module-reference coverage. All 300 shipped Python source modules have one module card and one unique anchor. All 202 package implementation-owner modules and all 5 external owner strings are represented. The 201 research owner strings from Appendix C are fully joined to package or external rows. This establishes the module-reference coverage. Execution records, command documentation, and release qualification remain separate evidence layers.

Appendix E. Executable-example records

Choosing and running an example. Use the record index to choose a mathematical task, then read the linked chapter before adapting the script. For a first packet-based program, start with EX-E-043 and Chapter 4. For a broader orientation, EX-E-007 is the public capability tour. The remaining records are independent entry points into particular topics; their order is not a required curriculum.

Each record separates the ingredients of a reproducible example:

Field	Read it as
Input (`I`)	The concrete data used by this example.
Hypotheses (`H`)	Conditions that must hold before interpreting the result.
Actions (`A`)	The sequence of operations performed by the script.
Expected result (`O`)	The values, relationships, or messages to compare with your run.
Certificates (`C`)	The evidence produced and the scope of the claim.
Failure boundary (`F`)	An invalid case or limit that helps explain the contract.
Reproducibility (`R`)	The interpreter, dependencies, invocation, and associated execution context.

Before running a record, check its language, dependencies, working directory, and file effects. Use the complete source script identified in the record: the prose and displayed output are a guide to that script, not a substitute for its imports and setup. Run the unchanged example first, inspect its result, then change one input or hypothesis at a time. Keep the original working example available for comparison.

The replay controller described below is a source-bundle tool, not an additional command installed by the wheel. A wheel-only installation does not supply every repository script or historical replay fixture. Obtain the matching source material before using those paths, and keep reference replay separate from a run against a newer installed package. For an ordinary individual run, use the entry point recorded on that example's card.

Interpreting a different result. First compare the installed package and dependency versions, then the input, working directory, backend, seed, and resource settings. Exact discrete results and explicit numerical tolerances are the meaningful comparison targets. Wall-clock timings, allocation peaks, device availability, and display formatting can vary. Read the record's expected-result and failure fields before deciding that a printed `False`, an expected exception, or an unavailable backend is an error in the example.

An expected-rejection example succeeds by detecting the declared invalid case. It does not establish that the rejected mathematical or hardware condition has become valid. This distinction is particularly useful for tampered persistence data, incomplete streams, unmet completion assumptions, and GPU qualification. For recovery steps, follow Appendix I and the relevant domain chapter rather than disabling the check that exposed the problem.

E.0 Scope, evidence and replay contract

All observations in this appendix belong to the recorded reference baseline and are bound by its source and wheel hashes. They are not a new replay of the final package.

The reference inventory contains exactly the **57 Python and eight PowerShell scripts** in `komorebi-math/examples`. Each script has one record identifier and one unique anchor. A record is a documentation unit, not a new theorem. Its local claim identifier ends in `CONTRACT`; mathematical theorem identifiers, where observed, are copied from runtime certificates.

The record schema retains the guide's original contract:

$$\mathcal{E} = (I, H, A, O, C, F, R).$$

Input and hypotheses are separated from the action and expected result. The machine-readable ledger adds source path, language, imports, public symbols, dependencies, platform, runtime class, seed, working directory, artifact hashes, cleanup, related tests and historical/current status. Exact input literals and helper functions remain available in the source file bound by each SHA-256 digest; the prose describes them rather than replacing them with an incomplete paraphrase.

Record completeness and runtime qualification are separate. All 65 records are filled. All 57 Python default invocations passed against the installed reference wheel. Seven reference PowerShell workflows await native qualification; the eighth is a historical `0.16.0a2` aggregate runner and is not applicable to the reference release. An unavailable or historical runner never contributes a runtime pass.

The Python replay. The controller checks the installed package version and all 366 package-file hashes, verifies the source-record inventory, copies only the example scripts to an isolated run location, disables optimization and runs each script in a bounded child process. Its own mathematical assertions remain active. The worker observes base `Certificate.require` calls without changing their return values or rejection behavior and rejects source-checkout imports. Each run must exit zero, satisfy its declared output/artifact predicates and leave no unexpected stderr.

The recorded run passed **190 predicates across 57 scripts**. It observed **841 base-certificate require calls across 104 distinct identifier strings**, including the possible no-ID category. These are repeated runtime observations, not 841 distinct theorems or new formal proofs. Certificates of other classes and Python assertions remain active but are not counted by this base-class observer.

Reference environment. CPython 3.13.5, Linux, NumPy 2.3.5, SciPy 1.17.0 and SymPy 1.14.0. Dependencies were inherited by the selected virtual environment. All package modules came from the separately installed wheel. Timings were measured with three workers and one BLAS thread per child, so they are diagnostic observations, not comparative performance claims.

Output matching. Exact discrete fields, stable text markers and selected JSON fields are checked explicitly. Declared numerical checks use tolerances. Profiling timings, Python allocation peaks and device availability are not equality targets. Some stable numeric text remains a reference-environment display check; cross-version formatting portability is not claimed. Raw stdout, stderr, module origins, certificate samples and artifact hashes are retained separately. The formatted output excerpts below may wrap long lines and are not raw-byte snapshots.

Failure variants. Each record names a relevant failure boundary. The shipped scripts execute some negative controls, such as payload tampering, broken holonomy and false quadrature exactness. Other variants identify hypotheses or required rejection behavior and are not automatically claimed as newly injected tests. The 134 example-record tests validate record/source correspondence, replay artifacts, missing-output rejection, tolerance behavior and corruption controls. Related package tests are a direct-shared-import crosswalk, not a theorem-coverage proof.

Reproduce from the delivery root. Select a Python interpreter in which the reference wheel and its dependencies are already installed. The controller does not install packages or use the network.

```
python tools/block37/replay_examples.py \
  --python /path/to/installed/python \
  --output /path/to/new-evidence-directory
```

The Python-scope exit code is zero only when all 57 contracts pass. Adding `--require-all-platforms` deliberately returns a nonzero result while native PowerShell evidence is missing. On Windows the same arguments may be written on one line; the POSIX line-continuation marks above are not PowerShell syntax.

E.1 Record index

Record	Example topic	Runtime scope
EX-E-001	Automatic and holonomic sequences	Python passed
EX-E-002	Semantic counts and observational profiling	Python passed
EX-E-003	Polyphase refinement coherence	Python passed
EX-E-004	Redundant analysis and operator blocks	Python passed
EX-E-005	Exact change of variables and a false-exactness adversary	Python passed
EX-E-006	Typed differentiation and integration through coordinates	Python passed
EX-E-007	Integrated public capability tour	Python passed
EX-E-008	Legendre, Chebyshev and derivative transport	Python passed
EX-E-009	Recurrence coordinates and naturality	Python passed
EX-E-010	Custom rational and algebraic finite series	Python passed
EX-E-011	Cyclic projection, reciprocal coefficients and zeros	Python passed
EX-E-012	Finite residue forest and occupancy	Python passed
EX-E-013	Finite Euclidean transfer and lattice spectrum	Python passed
EX-E-014	Euler data in Fibonacci defect coordinates	Python passed
EX-E-015	Symbolic backend and seed rank	Python passed
EX-E-016	Lattice gluing and Smith congruences	Python passed
EX-E-017	Multi-format reports and export artifacts	Python passed
EX-E-018	Feshbach self-energy and nonlocal memory	Python passed
EX-E-019	Filtered pages and moving-projector transport	Python passed
EX-E-020	Induced finite representation and unresolved descent	Python passed
EX-E-021	Affine, barycentric and formal changes	Python passed
EX-E-022	Fractional transfer and phase-type survival	Python passed

E.2 Python execution records

EX-E-001. Automatic and holonomic sequences

Source and placement. `komorebi-math/examples/automatic_holonomic.py`. Chapter 26, exact sequence execution. Local claim: `EX-E-001-CONTRACT`.

Input (I). Thue-Morse residue power 4, address 7, length 20; Apery prefix length 10.

Hypotheses and evidence class (H). EXACT finite sequences. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the automaton certificate at 256 terms and the holonomic certificate at 15 terms, then evaluate the two prefixes.

Expected result (O). The residue starts 1,0,0,1; the Apery prefix starts 1,5,73,1445. These are finite prefix checks, not evidence about all automatic or holonomic models.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-SEQ-AUTOMATIC`, `PSC-SEQ-HOLONOMIC`.

Failure boundary (F). Invalid residue addresses or negative prefix lengths must be rejected rather than silently wrapped.

Source API routes. `komorebi_math.sequences.apery_recurrence`, `komorebi_math.sequences.thue_morse_automaton`.

Reproducibility (R). `python examples/automatic_holonomic.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.902 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_sequences_models.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `399b420ae1364f5dcc84a73f8693b95e813f154e65d1e48839e084576c167081`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Thue Morse residue (1, 0, 0, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 1, 1,
 0)
Apery (Fraction(1, 1), Fraction(5, 1), Fraction(73, 1), Fraction(1445, 1),
Fraction(33001, 1), Fraction(819005, 1), Fraction(21460825, 1),
Fraction(584307365, 1), Fraction(16367912425, 1), Fraction(468690849005, 1))
```

EX-E-002. Semantic counts and observational profiling

Source and placement. `komorebi-math/examples/block11_semantic_profile.py`. Chapter 72, semantic contracts. Local claim: `EX-E-002-CONTRACT`.

Input (I). A two-dimensional order-2 tensor has diagonal entries 2 and -3. Use x/y coordinate packets, directions (2,3),(-1,4), two repetitions and one warmup.

Hypotheses and evidence class (H). EXACT counts / NUMERICAL evaluation / OBSERVATIONAL timing. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Construct the support, profile the declared jet, capture stream-writing stages, and require both the profile and golden-fixture certificates.

Expected result (O). Eight family addresses reduce to two active addresses and six pruned addresses; two planned derivative calls replace eight naive calls. Fifteen golden cases are present. Timings and allocation peaks are observations, not portable equality targets.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 6 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `KM-GOLDEN-011`, `PSC-I-T20`, `PSC-III-A10`, `PSC-III-A61`, `PSC-III-C08` (the complete set is in the execution record).

Failure boundary (F). Changing an exact count must fail the contract even when timing changes are allowed.

Source API routes. `komorebi_math.PacketSystem`, `komorebi_math.golden.run_behavioral_golden_fixture`, `komorebi_math.nonlinear.PacketJetFamily`, `komorebi_math.nonlinear.PolynomialDerivativeProvider`, `komorebi_math.nonlinear.packet_jet_support` and 1 more route in the JSON ledger.

Reproducibility (R). `python examples/block11_semantic_profile.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.107 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block10_sparse_autodiff.py`, `tests/test_operators_transfer.py`, `tests/test_nonlinear_trees.py` and 16 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `7c41b8bc55b671b6bca2a3c03e28bc4e9d5903037a8c07619e775e0b1355d2ab`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{
  "golden_cases": 15,
  "active_addresses": 2,
  "pruned_addresses": 6,
  "planned_derivative_calls": 2
}
```

EX-E-003. Polyphase refinement coherence

Source and placement. `komorebi-math/examples/block15_polyphase_refinement.py`. Chapters 12 and 14, refinement and polyphase. Local claim: `EX-E-003-CONTRACT`.

Input (I). The integer signal arange(29), a 4-to-12 refinement, and the tower (2,6,12).

Hypotheses and evidence class (H). EXACT finite indexing. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Refine and coarsen the finite signal, require reconstruction and tower-coherence certificates, and check the residue children of lane 1.

Expected result (O). The children are (1,5,9); both reconstructions equal the original signal exactly. The success line is emitted only after the explicit assertions.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `KM-B15-T01`, `KM-B15-T02`.

Failure boundary (F). An order that is not divisible by the coarse order is not a valid refinement.

Source API routes. `komorebi_math.refinement.PolyphaseRefinement`, `komorebi_math.refinement.PolyphaseRefinementTower`, `komorebi_math.signals.polyphase_analyze`.

Reproducibility (R). `python examples/block15_polyphase_refinement.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.828 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block16_release_qualification.py`, `tests/test_block17_upgrade_contract.py`, `tests/test_signals_polyphase_filterbanks.py` and 4 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `796d8e1a42fef3960f23d6af470ce7b616daacc35aeb933ebf5c944096b0b75f`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Block 15 polyphase refinement verified
```

EX-E-004. Redundant analysis and operator blocks

Source and placement. `komorebi-math/examples/block16_analysis_synthesis.py`. Chapter 20, analysis-synthesis. Local claim: `EX-E-004-CONTRACT`.

Input (I). Analysis rows (1,0),(0,1),(1,1),(1,-1); signal (3,-2); operator [[2,-1],[3,4]]; coordinate groups (0,2),(1,3).

Hypotheses and evidence class (H). NUMERICAL, declared certificate tolerances. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Build the canonical dual, reconstruct signal and operator blocks, then portable-serialize and restore the analysis system.

Expected result (O). Both reconstructions satisfy their numerical certificates; the signal is (3,-2). Redundancy is four coordinates for a two-dimensional signal, not an invertible square change of basis.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 249 package modules checked for import origin.

Observed base-certificate identifiers include `KM-AS-01`, `KM-AS-02`.

Failure boundary (F). A rank-deficient analysis matrix or coordinate groups that do not partition the coordinates must not be certified.

Source API routes. `komorebi_math.stable.AnalysisSynthesisSystem`, `komorebi_math.stable.dumps_portable`, `komorebi_math.stable.loads_portable`.

Reproducibility (R). `python examples/block16_analysis_synthesis.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.820 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Source SHA-256. `4403a6ef5db1aeb5e94840618ca5926b7a46f89840f1d7f81bd86285f53787d2`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
analysis-synthesis certificate {'valid': True, 'exactness': 'numerical',
'residuals': {'analysis_synthesis_left_inverse': 0.0}, 'tolerance': 1e-12,
'assumptions_checked': ('finite matrices', 'declared matrix dimensions',

```

EX-E-005. Exact change of variables and a false-exactness adversary

Source and placement. `komorebi-math/examples/block19_measure_integration_worked_example.py`. Chapters 47 through 49, exact integration. Local claim: `EX-E-005-CONTRACT`.

Input (I). Lebesgue measure on [0,1], y=2x+1, and f(y)=y^4-2y+1. Simpson uses 16 panels. The adversarial polynomial is defined in the shipped run() function.

Hypotheses and evidence class (H). EXACT rational identities / RIGOROUS finite quadrature bound. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compare pushforward, density and pullback integrals, pair three polynomial coordinate families, bound Simpson error, and test the node-vanishing adversary.

Expected result (O). Every exact integral and coordinate pairing is 106/5. The adversary samples to zero but integrates to 1/840, and its false exactness certificate is blocked.

Certificate and replay checks (C). The source contains 7 explicit `assert` statements and 9 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 5 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `INT.COORD.TRANSPORT`, `INT.EVAL.POLY.MOMENTS`, `INT.ID.COV.AFFINE`, `INT.ID.FTC`, `INT.ID.PUSHFORWARD` (the complete set is in the execution record).

Failure boundary (F). The shipped adversarial node polynomial is an executed negative control, not merely a suggested future test.

Source API routes. `komorebi_math.coordinates.connection_transform`, `komorebi_math.coordinates.euler_polynomial_family`, `komorebi_math.coordinates.fibonacci_polynomial_family`, `komorebi_math.coordinates.monomial_polynomial_family`, `komorebi_math.exceptions.ValidationError` and 13 more routes in the JSON ledger.

Reproducibility (R). `python examples/block19_measure_integration_worked_example.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.902 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_generating_block13.py`, `tests/test_certificates_registry.py`, `tests/test_algorithms_complexity_benchmarks.py` and 67 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `3c013d95c1be0d73b6bc4884d8bce2178f5766687d7ad5489e518544b7587480`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Block 19 worked example
  chart: y = 2x + 1, x in [0,1]
  pushed measure: (1/2) dy on [1,3]
  integrand: f(y) = y^4 - 2y + 1
  pullback: f(2x+1) = 16x^4 + 32x^3 + 24x^2 + 4x
  exact integral: 106/5
  monomials pairing: 106/5
  Euler polynomials pairing: 106/5
```

EX-E-006. Typed differentiation and integration through coordinates

Source and placement. `komorebi-math/examples/block20_typed_expression_worked_example.py`. Chapters 50 through 52, typed expressions. Local claim: `EX-E-006-CONTRACT`.

Input (I). G3(x)=x^3+2x in Fibonacci coordinates, degree-3 and degree-4 spaces, Euler coordinates, and integration over [0,1].

Hypotheses and evidence class (H). EXACT finite typed expressions. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compose antiderivative, coordinate changes and derivative; normalize, simplify, compile an optimal matrix chain, and round-trip the portable expression.

Expected result (O). The pipeline is I4, the integral is 5/4, and the declared chain costs are 244 versus 260. The affine weighted regression returns 106/5.

Certificate and replay checks (C). The source contains 12 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). Composition across incompatible spaces must fail type validation. A portable digest alone is not a mathematical identity proof.

Source API routes. `komorebi_math.expression.IdentityMap`, `komorebi_math.expression.MatrixChainPlan`, `komorebi_math.expression.PolynomialCoordinateSpace`, `komorebi_math.expression.affine_substitution`, `komorebi_math.expression.antiderivative` and 15 more routes in the JSON ledger.

Reproducibility (R). `python examples/block20_typed_expression_worked_example.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.069 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block20_expression_calculus.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `4e816b9e809d993ef141f011b4e9d800d432be59c5494ade945275c80290d2d7`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Block 20 typed finite expression worked example
Input: G_3(x) = x^3 + 2x
  J_0_in_Fibonacci: (-1/2, 0, 1/4, 0, 1/4)
  Fibonacci4_to_Euler4: (5/8, 3/2, 7/4, 1/2, 1/4)
  D_in_Euler: (3/2, 7/2, 3/2, 1)
  Euler3_to_Fibonacci3: (0, 0, 0, 1)
Integration covector: (1, 1/2, 4/3, 5/4)
Compiled pipeline normal form: I4
```

EX-E-007. Integrated public capability tour

Source and placement. `komorebi-math/examples/block21_public_capability_tour.py`. Chapter 74, publication capability tour. Local claim: `EX-E-007-CONTRACT`.

Input (I). Use the built-in polyphase, analysis-synthesis, integration, and typed-expression fixtures, eighteen Euler coefficients, and the 131-entry stable manifest.

Hypotheses and evidence class (H). MIXED exact and numerical finite checks. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Call sibling integration/expression examples and combine refinement, reconstruction, serialization and stable-contract checks in a JSON record.

Expected result (O). passed is true; stable symbol count is 131; the exact integral fields are 106/5 and 5/4. The record digest binds the canonical record, not external publication.

Certificate and replay checks (C). The source contains 12 explicit `assert` statements and 4 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 7 output/artifact predicates with exit code zero and 249 package modules checked for import origin.

Observed base-certificate identifiers include `CC.R1`, `INT.COORD.TRANSPORT`, `INT.EVAL.POLY.MOMENTS`, `INT.ID.COV.AFFINE`, `INT.ID.FTC` (the complete set is in the execution record).

Failure boundary (F). Retain the sibling example files. Copying this script alone causes an import failure; changing a capability field must fail the replay contract.

Source API routes. `komorebi_math.__version__`, `komorebi_math.coordinates.AnalysisSynthesisSystem`, `komorebi_math.coordinates.euler_fibonacci_coordinates`, `komorebi_math.export.persistence.dumps_portable`, `komorebi_math.export.persistence.loads_portable` and 3 more routes in the JSON ledger.

Reproducibility (R). `python examples/block21_public_capability_tour.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.052 seconds, measured under the shared reference profile; this is not a performance promise. Default invocation writes only stdout. The optional –output PATH creates directories and writes JSON; that alternate path is not part of this default replay.

Related package tests. `tests/test_block16_release_qualification.py`, `tests/test_coordinates_normalized_persistence.py`, `tests/test_block17_upgrade_contract.py` and 12 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `07e0a014e14aa62afbbf9bd5dc6464f534121caa215e84da10ff7e162422ddda`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{
  "passed": true,
  "package_version": "1.0.0b4",
  "stable_symbol_count": 131,
  "finite_integral": "106/5",
  "typed_integral": "5/4"
}
```

EX-E-008. Legendre, Chebyshev and derivative transport

Source and placement. `komorebi-math/examples/classical_coordinate_families.py`. Chapter 17, classical coordinate families. Local claim: `EX-E-008-CONTRACT`.

Input (I). Degree 8; Legendre, Chebyshev-T and monomial families; exact coefficient vector (1,2,…,9).

Hypotheses and evidence class (H). EXACT rational coordinate algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the connection certificate, invert the transformed coefficients, and compare transported differentiation with direct family differentiation.

Expected result (O). The exact coefficient round-trip holds and derivative matrices agree. The connection determinant is 21091995799875/2251799813685248.

Certificate and replay checks (C). The source contains 2 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `CC.P1`.

Failure boundary (F). A coefficient vector of the wrong degree must be rejected; a singular basis cannot supply an inverse.

Source API routes. `komorebi_math.coordinates.connection_transform`, `komorebi_math.coordinates.derivative_coordinate_operator`, `komorebi_math.coordinates.get_polynomial_family`, `komorebi_math.coordinates.transport_polynomial_operator`.

Reproducibility (R). `python examples/classical_coordinate_families.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.890 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `bd85e6b2ff7d9b5ced8a07e46e65be7dc8d01bebd4b37c564b78a23e13f79fd3`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Legendre to Chebyshev determinant: 21091995799875/2251799813685248
Chebyshev coordinates: (Fraction(62417, 16384), Fraction(803, 128),
Fraction(13583, 2048), Fraction(719, 128), Fraction(24493, 4096),
Fraction(609, 128), Fraction(10329, 2048), Fraction(429, 128),
Fraction(57915, 16384))
```

EX-E-009. Recurrence coordinates and naturality

Source and placement. `komorebi-math/examples/coordinate_calculus.py`. Chapter 16, coordinate calculus. Local claim: `EX-E-009-CONTRACT`.

Input (I). Values 1 through 8; recurrence coefficients (1,1) and (2,-1,3); degree-10 Euler and Fibonacci polynomial systems.

Hypotheses and evidence class (H). EXACT finite coordinate algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compare coordinate conversion with independent analysis in the target recurrence, then transport differentiation through the polynomial transform.

Expected result (O). Both displayed determinants are 1 and both explicit coordinate/naturality assertions pass.

Certificate and replay checks (C). The source contains 2 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). Do not confuse a finite defect-coordinate conversion with a claim that the input obeys either homogeneous recurrence.

Source API routes. `komorebi_math.coordinates.analyze_recurrence_coordinates`, `komorebi_math.coordinates.coordinate_change_between_recurrences`, `komorebi_math.coordinates.derivative_operator_in_family`, `komorebi_math.coordina

tes.euler_polynomial_family, komorebi_math.coordinates.euler_to_fibonacci_transform and 2 more routes in the JSON ledger.

Reproducibility (R). `python examples/coordinate_calculus.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.932 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_coordinates_recurrence.py`, `tests/test_coordinates_polynomials.py`, `tests/test_block19_integration.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `7085836c27f4dbd4f87db3c8b1f3c0d9c465a970564fc41b69608fcd0f3bd3fe`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
recurrence determinant 1
polynomial determinant 1
```

EX-E-010. Custom rational and algebraic finite series

Source and placement. `komorebi-math/examples/custom_generating_functions.py`. Chapters 21 through 24, generating functions. Local claim: `EX-E-010-CONTRACT`.

Input (I). Fibonacci rational function z/(1-z-z^2), the Catalan equation 1-y+zy^2=0 with y0=1, and a factorial-power basis of order 2.

Hypotheses and evidence class (H). EXACT finite prefixes. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Register both functions, evaluate finite prefixes, multiply normalized series and serialize a frozen degree-12 Catalan prefix.

Expected result (O). Fibonacci coefficient 12 is 144; Catalan coefficient 8 is 1430; the product coefficients are (2,3,-10,109,-512,2000). The frozen portable prefix round-trips.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `NGF.FINITE_NORMALIZED_SERIES`.

Failure boundary (F). A duplicate registry name or a non-simple algebraic branch must not be accepted as a new unambiguous function.

Source API routes. `komorebi_math.export.dumps_portable`, `komorebi_math.export.loads_portable`, `komorebi_math.generating.FiniteNormalizedSeries`, `komorebi_math.generating.FunctionRegistry`, `komorebi_math.generating.RationalDomain` and 4 more routes in the JSON ledger.

Reproducibility (R). `python examples/custom_generating_functions.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.815 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_generating_block13.py`, `tests/test_block10_execution_persistence.py`, `tests/test_generating_foundation.py` and 2 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `d42f374925bd24119a5177760718ad7d1f87f64fdd9d7eb0054f0129f9cd61a5`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'registry': ('catalan', 'fibonacci'), 'catalan_8': '1430', 'product': ('2',
 '3', '-10', '109', '-512', '2000'), 'portable_degree': 12}
```

EX-E-011. Cyclic projection, reciprocal coefficients and zeros

Source and placement. `komorebi-math/examples/cyclic_analytic.py`. Chapter 27, cyclic analytic systems. Local claim: `EX-E-011-CONTRACT`.

Input (I). Coefficients 0 through 14, cyclic order 4, reciprocal family order 2 and parameter 1, and the first four positive order-4 zeros.

Hypotheses and evidence class (H). EXACT coefficients / NUMERICAL roots. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the finite projection certificate, check secant coefficients and two theta-polynomial roots, and require the numerical zero certificate.

Expected result (O). Secant coefficients begin (1,1,5,61); the first zero is approximately 2.2214414691. Numerical root certificates do not make the roots exact algebraic values.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-IV-T01`, `PSC-IV-T54`.

Failure boundary (F). Invalid cyclic orders or insufficient root-search conditions must fail rather than be represented as an exact zero list.

Source API routes. `komorebi_math.analytic.CyclicDenominator`, `komorebi_math.analytic.cyclic_projection_certificate`, `komorebi_math.analytic.reciprocal_coefficients`, `komorebi_math.analytic.theta_polynomial`.

Reproducibility (R). `python examples/cyclic_analytic.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.934 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_analytic_appell_zeros.py`, `tests/test_analytic_cyclic_reciprocal.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `bc1eab12edd47ced72ea5669cc18b864a4d96a739a54d930cdc6391657b42e1e`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
cyclic analytic example passed (2.221441469079183, 6.66432440723755,
11.107207345395917, 15.550090283554283)
```

EX-E-012. Finite residue forest and occupancy

Source and placement. `komorebi-math/examples/deformation_support.py`. Chapter 56, deformation support. Local claim: `EX-E-012-CONTRACT`.

Input (I). Prime 2; residue levels {0,1}, {0,1,2,3}, {0,1,4,5}; nested coordinate subspaces of dimensions 3,2,1.

Hypotheses and evidence class (H). EXACT combinatorics / NUMERICAL subspaces. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Build the finite forest and nested occupancy report and require their certificates; evaluate the finite normal-crossing count at q=3, depth=2.

Expected result (O). Level sizes are (2,4,4), stable-core sizes (2,2,4), branch count 4, intersection dimension 1 and normal-crossing count 21.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-X-FINITE-OCCUPANCY`, `PSC-X-LIFT-FOREST`.

Failure boundary (F). This finite residue forest does not certify infinite persistence or an arithmetic deformation theorem.

Source API routes. `komorebi_math.deformation.nested_subspace_occupancy`, `komorebi_math.deformation.normal_crossing_count`, `komorebi_math.deformation.residue_forest`.

Reproducibility (R). `python examples/deformation_support.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.823 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_deformation_complex_support_companions.py`, `tests/test_deformation_forests_visibility_counting.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `bf7389f272d9d7caab6da2a3fe084b9ad8d86daae85f23b039adb3dfd17e5a11`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'level_sizes': (2, 4, 4), 'stable_core_sizes': (2, 2, 4), 'branch_count':
4, 'intersection_dimension': 1, 'normal_crossing_count_q3_depth2': 21}
```

EX-E-013. Finite Euclidean transfer and lattice spectrum

Source and placement. `komorebi-math/examples/euclidean_spectral.py`. Chapter 53, Euclidean quantum spectral systems. Local claim: `EX-E-013-CONTRACT`.

Input (I). Diagonal Hamiltonian (0,1,2), time step 0.2, a periodic 4-by-5 lattice and three explicitly bounded 2-by-2 Hamiltonians.

Hypotheses and evidence class (H). NUMERICAL finite-dimensional. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Check reflection positivity for the supplied vectors/times, compare dense eigenvalues with the lattice formula and require the finite tower report.

Expected result (O). The lattice spectra agree to numerical tolerance and the spectral-dimension value is nonnegative. The success line follows all checks.

Certificate and replay checks (C). The source contains 2 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VII-T56`, `PSC-VII-T70`.

Failure boundary (F). No continuum reflection-positivity, spectral-dimension limit or quantum field existence statement follows from this finite example.

Source API routes. `komorebi_math.quantum.BoundedHamiltonianTower`, `komorebi_math.quantum.EuclideanTransfer`, `komorebi_math.quantum.periodic_laplacian`, `komorebi_math.quantum.periodic_lattice_eigenvalues`, `komorebi_math.quantum.spectral_dimension`.

Reproducibility (R). `python examples/euclidean_spectral.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.226 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_quantum_transport_effective_spectral.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `bdb08297db34b86e1d9c2205b924a38d035782b83b2512a48e3bbb611bf37de1`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Euclidean and spectral example passed
```

EX-E-014. Euler data in Fibonacci defect coordinates

Source and placement. `komorebi-math/examples/euler_to_fibonacci_coordinates.py`. Chapters 17 and 65, classical-family conversion. Local claim: `EX-E-014-CONTRACT`.

Input (I). Eighteen Euler-sequence values generated by the named coordinate constructor.

Hypotheses and evidence class (H). EXACT finite recurrence coordinates. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the coordinate certificate and compare direct reconstruction with the variation-of-constants prefix.

Expected result (O). Initial data are (1,0); the reconstructed prefix begins 1,0,-1,0,5,0,-61,0. Sixteen defect entries accompany the two initial values.

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `CC.R1`.

Failure boundary (F). Dropping the defects would incorrectly claim a homogeneous Fibonacci recurrence for the Euler sequence.

Source API routes. `komorebi_math.coordinates.euler_fibonacci_coordinates`, `komorebi_math.coordinates.variation_of_constants_prefix`.

Reproducibility (R). `python examples/euler_to_fibonacci_coordinates.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.884 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_coordinates_normalized_persistence.py`, `tests/test_coordinates_recurrence.py`, `tests/test_coordinates_realization.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `5b362d07c86d368036865082633d60ccc6a6f300a8a5dfa3b5ff668740b59ddd`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
initial ('1', '0')
defects ('-2', '1', '6', '-5', '-66', '61', '1446', '-1385', '-51906',
'50521', '2753286', '-2702765', '-202063746', '199360981', '19590873126',
'-19391512145')
reconstructed ('1', '0', '-1', '0', '5', '0', '-61', '0', '1385', '0',
'-50521', '0', '2702765', '0', '-199360981', '0', '19391512145', '0')
```

EX-E-015. Symbolic backend and seed rank

Source and placement. `komorebi-math/examples/exact_backend.py`. Chapter 8, exact scalar backends. Local claim: `EX-E-015-CONTRACT`.

Input (I). SymPy nilpotent matrix [[0,1],[0,0]], two coordinate projectors and the direct sum of a size-2 Jordan block at 4 with a size-1 block at 4.

Hypotheses and evidence class (H). EXACT SymPy linear algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Construct the operator algebra and packet system with backend=sympy; print the packet certificate and compute the single-operator seed rank.

Expected result (O). Algebra dimension and seed rank are both 2. The printed packet certificate is valid and tagged exact.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`.

Failure boundary (F). This example requires SymPy. A missing optional symbolic backend is a dependency failure, not a successful NumPy substitute.

Source API routes. `komorebi_math.OperatorAlgebra`, `komorebi_math.PacketSystem`, `komorebi_math.single_operator_seed_rank`.

Reproducibility (R). `python examples/exact_backend.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. SymPy is imported directly and is required for this fixture. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.448 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_operators_transfer.py`, `tests/test_nonlinear_trees.py`, `tests/test_morphisms.py` and 16 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `28d479db2e1a20588c940020c513b88b7e9b119d6a7bae8c8edde5c3796aaa08`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
algebra dimension: 2
{
  "assumptions_checked": [
    "common dimension",
    "idempotence",
    "annihilation",
    "completeness"
  ],
```

EX-E-016. Lattice gluing and Smith congruences

Source and placement. `komorebi-math/examples/exact_lattice_separation.py`. Chapter 13, lattice separation. Local claim: `EX-E-016-CONTRACT`.

Input (I). P0=[[1,1/4],[0,0]], P1=I-P0, split basis [[1,-1],[0,4]], prime 2; congruence diag(2,4) on three variables at depth 3.

Hypotheses and evidence class (H). EXACT rational/integer lattice algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the gluing-weight certificate and solve the exact prime-power congruence.

Expected result (O). Projector weights (2,2), gluing invariant factors (1,4), and exactly 64 solutions.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-II-D12`, `PSC-II-SNF`, `PSC-II-T13`, `PSC-II-T18`.

Failure boundary (F). A composite prime parameter, invalid split basis or inconsistent congruence must not yield a valid solution certificate.

Source API routes. `komorebi_math.LatticePacketData`, `komorebi_math.SmithCongruenceProblem`.

Reproducibility (R). `python examples/exact_lattice_separation.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. SymPy is imported directly and is required for this fixture. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.344 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Source SHA-256. `9b79fbd8bf454b9a68237a62d54873fc906bcfc165354f9758b95ad8db1d2fe3`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
projector weights: (2, 2)
gluing factors: (1, 4)
congruence solutions: 64
```

EX-E-017. Multi-format reports and export artifacts

Source and placement. `komorebi-math/examples/export_reports.py`. Chapters 59 through 60 and 70, reports and rendering. Local claim: `EX-E-017-CONTRACT`.

Input (I). Twenty-four Fibonacci values and the certified Euler coordinate at index 20, depth 2. Defaults: output=komorebi_export_demo, engine=auto.

Hypotheses and evidence class (H). EXACT data / FORMAT and compiler checks. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Build a MathDocument, export text/Markdown/HTML/TeX and sequence CSV/JSON, optionally compile PDFs, then build an export ZIP.

Expected result (O). The JSON and CSV contain the exact 24 indexed Fibonacci values. All declared files are nonempty; export certificates pass. PDF is conditional on an available LaTeX engine.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 6 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-IX-T19`.

Failure boundary (F). The script uses overwrite=True. Run only in a disposable output directory. Missing LaTeX must be distinguished from a failed available compiler.

Source API routes. `komorebi_math.EulerLocalCoordinates`, `komorebi_math.export.DocumentMetadata`, `komorebi_math.export.ExportOptions`, `komorebi_math.export.LatexCompileOptions`, `komorebi_math.export.MathDocument` and 5 more routes in the JSON ledger.

Reproducibility (R). `python examples/export_reports.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 8.433 seconds, measured under the shared reference profile; this is not a performance promise. Writes komorebi_export_demo under the replay working directory with overwrite=True. The runner retains all exports and their hashes. Delete only the disposable run directory after preserving evidence.

Related package tests. `tests/test_export_renderers.py`, `tests/test_export_cli.py`, `tests/test_sequences_execution.py` and 2 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `ea0aeca271247086dd1b8993c23b303254e62e27c130e2eee5c2774a1995b893`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
No stdout. Verified artifact files:
komorebi_export_demo/fibonacci.csv
komorebi_export_demo/fibonacci.json
komorebi_export_demo/fibonacci_bundle.zip
komorebi_export_demo/fibonacci_bundle.zip.manifest
komorebi_export_demo/report.html
komorebi_export_demo/report.komorebi.log
komorebi_export_demo/report.md
komorebi_export_demo/report.pdf
komorebi_export_demo/report.tex
komorebi_export_demo/report.txt
```

EX-E-018. Feshbach self-energy and nonlocal memory

Source and placement. `komorebi-math/examples/feshbach_memory.py`. Chapter 46, Feshbach memory kernels. Local claim: `EX-E-018-CONTRACT`.

Input (I). The shipped 4-by-4 dissipative operator, retained indices (0,1), resolvent points 2+0.3i and 2+0.2i, horizon 15 and 3000 quadrature points.

Hypotheses and evidence class (H). NUMERICAL finite resolvent and quadrature. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require resolvent and memory-kernel certificates, then inspect the zero-time kernel and local-closure diagnostic.

Expected result (O). The zero-time kernel is diag(0.12,-0.1). Exact local closure is False by design: memory remains present.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VI-T28`, `PSC-VI-T30`.

Failure boundary (F). Requiring every printed Boolean to be true would be wrong. The negative local-closure diagnostic is the intended result.

Source API routes. `komorebi_math.dynamics.FeshbachReduction`.

Reproducibility (R). `python examples/feshbach_memory.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.201 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_dynamics_feshbach.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `cd45ded4bbf8c931b7f186384781ad8839c4a9073744ee6ce118c544d48de346`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
self energy at z=2+0.3i:
[[ 0.03960396-0.0039604j   0.00143203-0.00027196j]
 [-0.        +0.j         -0.02918455+0.00257511j]]
memory kernel at zero:
[[ 0.12  0.  ]
 [ 0.   -0.1 ]]
exact local closure: False
```

EX-E-019. Filtered pages and moving-projector transport

Source and placement. `komorebi-math/examples/filtered_transport.py`. Chapters 42 and 44, filtered transport. Local claim: `EX-E-019-CONTRACT`.

Input (I). A one-dimensional cochain map over prime 5 with shifted filtration; a 2-by-2 rotation generator of speed 0.4 and 32 coarse time steps.

Hypotheses and evidence class (H). EXACT finite filtration / NUMERICAL transport. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the finite spectral-sequence certificate and compare coarse/fine Kato transport after a derivative check.

Expected result (O). Page dimensions/ranks are (2,0),(2,1),(0,0); the coarse/fine transport difference must be at most 1e-6.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-III-C60`, `PSC-III-D56`, `PSC-III-S54`.

Failure boundary (F). A filtration that the differential does not preserve must not be certified. Coarse/fine agreement is not a global error theorem.

Source API routes. `komorebi_math.dynamics.matrix_exponential`, `komorebi_math.nonlinear.FilteredVectorSpace`, `komorebi_math.nonlinear.FiniteFilteredCochainComplex`, `komorebi_math.nonlinear.KatoTransport`, `komorebi_math.nonlinear.MovingPacketSystem`.

Reproducibility (R). `python examples/filtered_transport.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.288 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block4_hardening.py`, `tests/test_nonlinear_transport.py`, `tests/test_quantum_transport_effective_spectral.py` and 1 more file in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `ecd83b558196743d21639f48cafc0f111a552ed9e421f63023126fddf3acd2bb`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
page 0 dimension 2 rank 0
page 1 dimension 2 rank 1
page 2 dimension 0 rank 0
transport coarse-fine difference: 4.649628121515814e-15
```

EX-E-020. Induced finite representation and unresolved descent

Source and placement. `komorebi-math/examples/finite_image_clifford.py`. Chapter 58, finite-image and Clifford models. Local claim: `EX-E-020-CONTRACT`.

Input (I). C4 with subgroup C2 and character (1,-1), symmetric degree 3, and three supplied Clifford steps forming EIE.

Hypotheses and evidence class (H). FINITE representation model / CONDITIONAL descent. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the induced representation, packet-dimension and finite Clifford report certificates.

Expected result (O). Induced dimension 2, symmetric packet dimensions (2,2), word EIE, depth 1 and unresolved extension step (0,).

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `KM-INDUCED-REPRESENTATION`, `PSC-LANG-CLIFFORD-DEPTH`, `PSC-LANG-MONOMIAL-ORBITS`.

Failure boundary (F). The unresolved extension must remain visible. A finite Clifford word is not evidence that an unattached descent has been constructed.

Source API routes. `komorebi_math.langlands.finite_image.CliffordStep`, `komorebi_math.langlands.finite_image.CliffordTower`, `komorebi_math.langlands.finite_image.InducedRepresentation`, `komorebi_math.langlands.finite_image.LinearCharacter`, `komorebi_math.langlands.finite_image.MonomialAction` and 1 more route in the JSON ledger.

Reproducibility (R). `python examples/finite_image_clifford.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.867 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_langlands_finite_image.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `c7876aa3661747d437d26b4174acf8b3186017c9fd2cbd2ca94d871e50f74f16`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'induced_dimension': 2, 'symmetric_packet_dimensions': (2, 2),
'clifford_word': 'EIE', 'clifford_depth': 1, 'unresolved_extension_steps':
(0,)}
```

EX-E-021. Affine, barycentric and formal changes

Source and placement. `komorebi-math/examples/formal_affine_coordinate_changes.py`. Chapters 15 through 16, formal affine changes. Local claim: `EX-E-021-CONTRACT`.

Input (I). Origin (3,-2), basis ((1,1),(1,-1)), local point (5/2,-3/2); triangle ((0,0),(2,0),(0,3)); formal coefficients (0,1,1,-2,3).

Hypotheses and evidence class (H). EXACT finite rational algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Invert affine and barycentric coordinates and pull/push a finite series through the certified formal coordinate change.

Expected result (O). Cartesian point (4,2), barycentric image (2/3,3/2), and formal pullback (3,4,3,-8,26); all finite round-trips hold.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `CC.J1`.

Failure boundary (F). A singular affine basis, degenerate simplex or zero formal linear coefficient must not be treated as invertible.

Source API routes. `komorebi_math.coordinates.BarycentricCoordinateSystem`, `komorebi_math.coordinates.FormalCoordinateChange`, `komorebi_math.coordinates.affine_basis_transform`.

Reproducibility (R). `python examples/formal_affine_coordinate_changes.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.837 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_coordinates_general_persistence.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `e5503b36732eb502882387df8b314cf8672b2d3178721a9895b6e3fea4831e8b`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Cartesian point: (Fraction(4, 1), Fraction(2, 1))
barycentric point: (Fraction(2, 3), Fraction(3, 2))
formal pullback: (Fraction(3, 1), Fraction(4, 1), Fraction(3, 1),
Fraction(-8, 1), Fraction(26, 1))
```

EX-E-022. Fractional transfer and phase-type survival

Source and placement. `komorebi-math/examples/fractional_survival.py`. Chapter 46, fractional survival. Local claim: `EX-E-022-CONTRACT`.

Input (I). Positive diagonal operator (1,4,9), exponent 1/2, time 0.7; two-state subgenerator [[-0.7,0.2],[0.3,-0.6]] and initial mass (1,0).

Hypotheses and evidence class (H). NUMERICAL finite-dimensional. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compute the spectral square root and transfer, then require the survival and identity certificates.

Expected result (O). Square-root spectrum (1,2,3), survival at time 1 approximately 0.6703200460 and mean lifetime 2.5.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VI-T32`, `PSC-VI-T33`.

Failure boundary (F). Invalid probability mass or a non-transient subgenerator must not be accepted as a normalized survival model.

Source API routes. `komorebi_math.dynamics.PhaseTypeSurvival`, `komorebi_math.dynamics.fractional_power`, `komorebi_math.dynamics.fractional_semigroup`.

Reproducibility (R). `python examples/fractional_survival.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.206 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block4_hardening.py`, `tests/test_dynamics_fractional_green_feynman_survival.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `bd0e7f3364aaa98a964a6dbbd3358f970b2f020699599fb8aa74ceee58b97a90`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
square root spectrum: [1. 2. 3.]
fractional transfer diagonal: [0.4965853  0.24659696 0.12245643]
survival at t=1: 0.6703200460356394
mean lifetime: 2.5
```

EX-E-023. Finite Frobenius separator and carrier multiplicities

Source and placement. `komorebi-math/examples/frobenius_companions.py`. Chapter 56, Frobenius companions. Local claim: `EX-E-023-CONTRACT`.

Input (I). Frobenius polynomials at 2 and 3; trace rows (1,1),(1,-1),(2,0); observed trace (5,1); carrier capacities (4,2).

Hypotheses and evidence class (H). EXACT finite separator / CONDITIONAL carrier input. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Build the finite separator, require its certificate, recover multiplicities and select within the declared carrier.

Expected result (O). Rank 2, separating places (2,3), multiplicities (3,2), selected rho1=3 and rho2=2.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-X-FROBENIUS-SEPARATOR`.

Failure boundary (F). This verifies supplied finite traces and capacities, not the existence of compatible global Galois or automorphic objects.

Source API routes. `komorebi_math.deformation.CompatibleCarrier`, `komorebi_math.deformation.FrobeniusSpine`, `komorebi_math.deformation.finite_frobenius_separator`.

Reproducibility (R). `python examples/frobenius_companions.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.962 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_deformation_complex_support_companions.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `1bd76f1683ad2a7827e1d018c229ebae503dad726467e125f683ba39cd144b14`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'spine_rank': 2, 'separating_places': (2, 3), 'multiplicities': (3, 2),
'selected_carrier': {'rho1': 3, 'rho2': 2}}
```

EX-E-024. Three-basis exact atlas

Source and placement. `komorebi-math/examples/general_coordinate_atlas.py`. Chapters 15 through 19, coordinate atlas. Local claim: `EX-E-024-CONTRACT`.

Input (I). Standard basis in dimension 3, upper-unitriangular shear, diagonal scaling (2,3,5), and vector (7,-3,11).

Hypotheses and evidence class (H). EXACT finite rational algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Register direct and inverse changes, compare the direct and two-step paths, then synthesize from scaled coordinates.

Expected result (O). The direct route is standard to scaled; exact coordinates are (7/2,-1,11/5) and reconstruct the vector.

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `CC.A2`.

Failure boundary (F). A conflicting direct edge must produce a noncommuting-diagram diagnostic, not silently replace the disagreement.

Source API routes. `komorebi_math.coordinates.CoordinateAtlas`, `komorebi_math.coordinates.CoordinateSystem`, `komorebi_math.coordinates.basis_from_matrix`, `komorebi_math.coordinates.standard_basis`.

Reproducibility (R). `python examples/general_coordinate_atlas.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.890 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_coordinates_general_persistence.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `9f5fd4259beacf4b50f3b7867b0c81174a69219db6965ca5b2c60232ac8f3779`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
path: ('standard', 'scaled')
scaled coordinates: (Fraction(7, 2), Fraction(-1, 1), Fraction(11, 5))
```

EX-E-025. Gauge-invariant gluing with a broken-cycle control

Source and placement. `komorebi-math/examples/holonomy.py`. Chapter 40, holonomy. Local claim: `EX-E-025-CONTRACT`.

Input (I). Two shear matrices A,B, direct edge C=B A, three vertices and invertible diagonal gauges. The negative graph uses direct edge 2C.

Hypotheses and evidence class (H). NUMERICAL finite matrix relations. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require gluing before and after gauge change and assert that the deliberately broken graph is invalid.

Expected result (O). One fundamental cycle, gauge-invariant gluing True and broken cycle detected True.

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-III-T40`.

Failure boundary (F). The shipped 2C edge is an executed negative control. Flatness is only asserted for this finite graph.

Source API routes. `komorebi_math.TransportEdge`, `komorebi_math.TransportGraph`.

Reproducibility (R). `python examples/holonomy.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.875 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Source SHA-256. `c8eb15199c3e3b812f13152a5fefa2b4b0a91a4a50412e84487db91a3eec5487`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
fundamental cycles: 1
gauge invariant gluing: True
broken cycle detected: True
```

EX-E-026. Quantum transport and Feshbach Laplace identity

Source and placement. `komorebi-math/examples/kato_feshbach.py`. Chapters 45 through 46, Kato-Feshbach dynamics. Local claim: `EX-E-026-CONTRACT`.

Input (I). Rotation generator speed 0.3, 160 time steps, Hamiltonian [[0.2,0.3],[0.3,1.4]], retained coordinate 0 and z=2.1+0.4i.

Hypotheses and evidence class (H). NUMERICAL finite quantum model. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require transport and resolvent certificates and compare kernel.laplace(-i z) with i times self-energy.

Expected result (O). The explicit Laplace identity holds with atol=1e-8 and the success line follows the checks.

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-III-T58`, `PSC-VI-T28`.

Failure boundary (F). A singular resolvent or a non-Hermitian input outside the constructor contract must not receive the same certificate.

Source API routes. `komorebi_math.dynamics.matrix_exponential`, `komorebi_math.quantum.KatoTransport`, `komorebi_math.quantum.MovingPacketSystem`, `komorebi_math.quantum.QuantumFeshbachReduction`.

Reproducibility (R). `python examples/kato_feshbach.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.306 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block4_hardening.py`, `tests/test_nonlinear_transport.py`, `tests/test_quantum_transport_effective_spectral.py` and 1 more file in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `a7bf14e656dab624dcee56b49bf5238a79e054d5ae16572e8c1a8f934cb55576`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Kato and Feshbach example passed
```

EX-E-027. Dyadic and odd-prime Euler truncations

Source and placement. `komorebi-math/examples/local_euler_coordinates.py`. Chapters 17 and 25, local Euler coordinates. Local claim: `EX-E-027-CONTRACT`.

Input (I). Euler index 20 and depth 2 for primes 2 and 5.

Hypotheses and evidence class (H). EXACT rational / prime-power congruence. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compute each local truncation, require its certificate and print exact, truncated, modulus and error fields.

Expected result (O). The exact Euler value is 370371188237525 for both primes. The certified moduli are 2048 and 15625; the truncations are p-adic approximations, not small real errors.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 5 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-IX-T19`.

Failure boundary (F). Do not interpret a large real error as failed p-adic accuracy. Prime/compression hypotheses still apply.

Source API routes. `komorebi_math.arithmetic.EulerLocalCoordinates`.

Reproducibility (R). `python examples/local_euler_coordinates.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.815 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_arithmetic_euler.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `89ae0fd16f1960e0ae167bb68024f3634ce5dfacaad81203cd12878034811979`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'prime': 2, 'exact': Fraction(370371188237525, 1), 'truncated':
'8804179016755/231', 'modulus': 2048, 'error': '85546940303851520/231'}
{'prime': 5, 'exact': Fraction(370371188237525, 1), 'truncated':
'86777696087933558237525', 'modulus': 15625, 'error':
'-8677769571756237000000'}
```

EX-E-028. Low-rank structured solve and recompression

Source and placement. `komorebi-math/examples/low_rank_recompression.py`. Chapter 29, low-rank recompression. Local claim: `EX-E-028-CONTRACT`.

Input (I). NumPy generator seed 7; diagonal blocks 2I2 and 3I2; two small 4-by-2 factors and a generated right-hand side.

Hypotheses and evidence class (H). NUMERICAL structured algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Apply and invert the structured operator, form an exact structured product and recompress it to rank 2.

Expected result (O). Solve residual is below 1e-10, product rank bound 4, compressed rank 2; spectral compression error is finite and nonzero for this fixture.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VIII-T12`.

Failure boundary (F). Recompression is an approximation. Rank reduction does not imply zero spectral error or a universal speedup.

Source API routes. `komorebi_math.algorithms.BlockDiagonalLowRankOperator`, `komorebi_math.algorithms.BlockDiagonalOperator`.

Reproducibility (R). `python examples/low_rank_recompression.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. NumPy default_rng(7).

Runtime and filesystem. Recorded Linux replay: 0.870 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_algorithms_structured.py`, `tests/test_algorithms_low_rank.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `83fb6064816002498a5eeab4e7b39af492d6e16f0b2c840af6a2a2672fb4fdd8`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
solve residual 0.0
product rank bound 4
compressed rank 2
compression spectral error 0.00024475675260188207
```

EX-E-029. Finite-mask carry and rational-mask Mahler compilation

Source and placement. `komorebi-math/examples/mahler_cartier_compilers.py`. Chapters 23, 25, and 26, Mahler-Cartier execution. Local claim: `EX-E-029-CONTRACT`.

Input (I). Mask (1,1,1), radix 2; A=(1,1), B=(1,-1), prime 5; coefficient index 10^18+12345; degree-4 coboundary problem.

Hypotheses and evidence class (H). EXACT finite-state / modular arithmetic. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Certify 500 Stern-shift coefficients, evaluate a bounded-dimensional Cartier state and solve the exact polynomial coboundary.

Expected result (O). Cartier dimension 2, large-index residue 0 and coboundary (1,2). The Cartier model solves B(z)F(z)=A(z)F(z^5), F(0)=1, not the ordinary rational series A(z)/B(z).

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `GF-FINITE-MASK-CARRY`.

Failure boundary (F). Conflating a rational mask with a rational generating function would give the wrong coefficient expectation. Composite primes must be rejected.

Source API routes. `komorebi_math.generating.compile_cartier_linear_representation`, `komorebi_math.generating.compile_finite_mask_carry_plan`, `komorebi_math.generating.solve_polynomial_coboundary`.

Reproducibility (R). `python examples/mahler_cartier_compilers.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.973 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_generating_block13.py`, `tests/test_generating_cartier_padic.py`, `tests/test_generating_domains.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `b66b364ec0168205a96288549652ff7d3316b9b264e1fc14d5de853ee4974088`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'stern_shift_prefix': (Fraction(1, 1), Fraction(1, 1), Fraction(2, 1),
Fraction(1, 1), Fraction(3, 1), Fraction(2, 1), Fraction(3, 1), Fraction(1,
1), Fraction(4, 1), Fraction(3, 1), Fraction(5, 1), Fraction(2, 1),
Fraction(5, 1), Fraction(3, 1), Fraction(4, 1), Fraction(1, 1), Fraction(5,
1), Fraction(4, 1), Fraction(7, 1), Fraction(3, 1)), 'cartier_dimension': 2,
 'large_index_value_mod_5': 0, 'coboundary': (Fraction(1, 1), Fraction(2,
1))}
```

EX-E-030. Lumping and Bayesian sufficiency

Source and placement. `komorebi-math/examples/markov_bayes.py`. Chapter 45, Markov and Bayesian dynamics. Local claim: `EX-E-030-CONTRACT`.

Input (I). The shipped 4-by-4 column-conservative generator, partition (0,0,1,1), prior (0.1,0.2,0.3,0.4) and likelihood (2,2,0.5,0.5).

Hypotheses and evidence class (H). NUMERICAL finite stochastic model. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require lumpability and coarse-posterior certificates, then inspect fixed sufficiency on the supplied likelihood.

Expected result (O). Coarse generator [[-0.1,0],[0.1,0]], coarse posterior (12/19,7/19) numerically, and fixed sufficiency True.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VI-T21`, `PSC-VI-T36`.

Failure boundary (F). A likelihood that varies within a block need not be fixed sufficient; the example is not a universal sufficiency claim.

Source API routes. `komorebi_math.dynamics.BayesianPartition`, `komorebi_math.dynamics.MarkovLumping`.

Reproducibility (R). `python examples/markov_bayes.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.841 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_semigroups_markov.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `7a4361d727bfbb5bedbc707377777f3475032df09e3ef1c5c8643ccdab64c591`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
coarse generator:
[[-0.1  0. ]
 [ 0.1  0. ]]
coarse posterior: [0.63157895 0.36842105]
fixed sufficient: True
```

EX-E-031. Faà di Bruno and sparse packet support

Source and placement. `komorebi-math/examples/nonlinear_jets_composition.py`. Chapter 38, nonlinear jet composition. Local claim: `EX-E-031-CONTRACT`.

Input (I). Scalar outer quadratic and inner x+x^2 at x=2 with directions 3,4; then a two-output diagonal quadratic tensor.

Hypotheses and evidence class (H). EXACT scalar example / NUMERICAL packet example. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the composed directional-derivative certificate and reconstruct the two-dimensional packet-jet family from its support.

Expected result (O). The scalar second directional derivative is 888 with two set-partition terms; only the x/xx and y/yy packet jets are nonzero.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-III-C08`, `PSC-III-T07`, `PSC-III-T10`.

Failure boundary (F). Wrong derivative order, direction count or dimension must fail rather than fabricate missing derivatives.

Source API routes. `komorebi_math.Exactness`, `komorebi_math.PacketSystem`, `komorebi_math.nonlinear.PacketJetFamily`, `komorebi_math.nonlinear.PolynomialDerivativeProvider`, `komorebi_math.nonlinear.faa_di_bruno` and 1 more route in the JSON ledger.

Reproducibility (R). `python examples/nonlinear_jets_composition.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.884 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_nonlinear_correction_elimination.py`, `tests/test_block10_sparse_autodiff.py`, `tests/test_operators_transfer.py` and 19 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `9d5465383605a4ef8878f6ba72c0fc9b77c6fe3f46e47623fa001c88db382655`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
second directional derivative: 888
set-partition terms: 2
nonzero packet jets: (PacketJetAddress(output='x', inputs=('x', 'x')),
PacketJetAddress(output='y', inputs=('y', 'y')))
```

EX-E-032. Tree expansion, Schur elimination and obstruction

Source and placement. `komorebi-math/examples/nonlinear_trees_elimination.py`. Chapters 39 and 41, tree elimination. Local claim: `EX-E-032-CONTRACT`.

Input (I). Fixed-point seed 0.1 with quadratic nonlinearity, depth 4 and radius 0.2; retained map 3x+2y, hidden map y-4x; singular map (y,x^2).

Hypotheses and evidence class (H). NUMERICAL finite expansion / stated majorant bound. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require tree and majorant certificates, compute implicit/reduced derivatives, and solve the Lyapunov-Schmidt range equation at x=0.3.

Expected result (O). Finite tree sum 0.11256641, implicit derivative 4, reduced derivative 11 and reduced obstruction 0.09. The nonzero obstruction is not a solution.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 4 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-III-T14`, `PSC-III-T14A`, `PSC-III-T33`, `PSC-III-T41`.

Failure boundary (F). A nonzero reduced obstruction must not be reported as a root of the full nonlinear system.

Source API routes. `komorebi_math.nonlinear.CallableDerivativeProvider`, `komorebi_math.nonlinear.LyapunovSchmidtReduction`, `komorebi_math.nonlinear.NonlinearSchurElimination`, `komorebi_math.nonlinear.PolynomialFixedPointProblem`, `komorebi_math.nonlinear.majorant_convergence`.

Reproducibility (R). `python examples/nonlinear_trees_elimination.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.854 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Source SHA-256. `2aaf93d61b99676bc6725ff4adfc2bbc066f9ce9bf07c9e817a7e56a1e771cd5`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
finite tree sum: 0.11256641000000002
Picard tail bound at depth 4: 0.004266666666666668
implicit derivative: [[4.-0.j]]
reduced derivative: [[11.+0.j]]
reduced obstruction: [0.09]
```

EX-E-033. Cokernel obstruction and prime-power branches

Source and placement. `komorebi-math/examples/obstruction_lifting.py`. Chapter 40, obstruction lifting. Local claim: `EX-E-033-CONTRACT`.

Input (I). Exact matrix diag(1,0), target (0,1); polynomial x^2-1 over prime 3, roots 1 and 2 mod 3, depths 1 through 5.

Hypotheses and evidence class (H). EXACT finite prime-power algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Solve the linear obstruction and construct the finite lift tree from the two roots.

Expected result (O). The cokernel obstruction is nonzero with dimension 1; there are five levels and two terminal branches of length five.

Certificate and replay checks (C). The source contains 4 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-III-T28`.

Failure boundary (F). Nonvanishing obstruction is intentional. Five verified depths alone are not an unqualified infinite lifting statement.

Source API routes. `komorebi_math.LinearObstructionProblem`, `komorebi_math.PolynomialLiftProblem`, `komorebi_math.nonlinear.build_lift_tree`.

Reproducibility (R). `python examples/obstruction_lifting.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. SymPy is imported directly and is required for this fixture. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 1.440 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_lifting.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `123e7c4c7bc12fef7295c39c68d5c96f10bf37fee9c6920811e66a30cd9d1316`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
obstruction coordinates: (1,)
lift levels: 5
terminal branches: 2
```

EX-E-034. Finite candidate-tree optimization

Source and placement. `komorebi-math/examples/packet_compiler.py`. Chapters 28 through 30, packet compilation. Local claim: `EX-E-034-CONTRACT`.

Input (I). The shipped five-node tree with keep costs/errors, split overheads 0.5 and 0.2, Lagrangian penalty 4, error budget 6 and error unit 0.1.

Hypotheses and evidence class (H). FINITE combinatorial optimization / floating input costs. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compute Lagrangian and budget plans and enumerate the finite Pareto frontier.

Expected result (O). Both selected leaves are (left,right); the frontier has the root plan and two split plans. The budget is the declared quantized error budget, not a cost cap of six.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). An infeasible budget returns no plan. Optimality is relative to the supplied candidate tree, not all possible representations.

Source API routes. `komorebi_math.algorithms.TreeNode`, `komorebi_math.algorithms.compile_tree_budget`, `komorebi_math.algorithms.compile_tree_lagrangian`, `komorebi_math.algorithms.pareto_frontier`.

Reproducibility (R). `python examples/packet_compiler.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.925 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_algorithms_compiler.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `a6509e6230b080d88a75c22c7b37d54f102de1a9d54b57711899bdf001134511`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Lagrangian leaves ('left', 'right')
budget leaves ('left', 'right')
Pareto points [(9.0, 0.0, ('root',)), (7.5, 0.30000000000000004, ('left',
'right')), (5.2, 0.8999999999999999, ('left', 'right_low', 'right_high'))]
```

EX-E-035. Structured packet intermediate representation

Source and placement. `komorebi-math/examples/packet_ir.py`. Chapter 28, packet intermediate representation. Local claim: `EX-E-035-CONTRACT`.

Input (I). Layout (2,1), matrix [[2,1,0],[0,3,0],[4,0,5]], vector (1,2,3).

Hypotheses and evidence class (H). NUMERICAL apply / EXACT layout counts. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Create a PacketIR, require its certificate, apply it and evaluate the declared cost model.

Expected result (O). Result (4,6,19), support {(0,0),(1,0),(1,1)}, seven stored entries and fourteen modeled flops.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VIII-T01`.

Failure boundary (F). Modeled flops are not measured runtime. An incompatible vector or layout must be rejected.

Source API routes. `komorebi_math.algorithms.PacketIR`, `komorebi_math.algorithms.PacketLayout`, `komorebi_math.algorithms.packet_cost_estimate`.

Reproducibility (R). `python examples/packet_ir.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.963 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_algorithms_complexity_benchmarks.py`, `tests/test_algorithms_discovery_gpu.py`, `tests/test_algorithms_krylov.py` and 1 more file in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `977ea6b7e2944b44fb12e46529d74959cbc21b7570fba73ff5783a50738718bf`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
support [(0, 0), (1, 0), (1, 1)]
result [ 4.  6. 19.]
stored entries 7
modeled flops 14
```

EX-E-036. Polyphase and Haar reconstruction

Source and placement. `komorebi-math/examples/polyphase_filterbank.py`. Chapters 14 and 35, polyphase filter banks. Local claim: `EX-E-036-CONTRACT`.

Input (I). Signal arange(16), modulus 4, FIR taps (1/4,1/2,1/4), Haar depth 3 and pruning leaves (0,10,110,111).

Hypotheses and evidence class (H). EXACT indexing / NUMERICAL transforms. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require polyphase/convolution certificates and verify Haar and pruned-tree reconstruction.

Expected result (O). Four channels of length four, filtered length 18 and fifteen packet-tree nodes; both reconstruction assertions pass.

Certificate and replay checks (C). The source contains 2 explicit `assert` statements and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-V-T02`, `PSC-V-T07`, `PSC-V-T13`.

Failure boundary (F). An invalid pruning cover must not masquerade as a complete reconstruction.

Source API routes. `komorebi_math.signals.HaarPacketTree`, `komorebi_math.signals.haar_analyze`, `komorebi_math.signals.haar_synthesize`, `komorebi_math.signals.polyphase_analyze`, `komorebi_math.signals.polyphase_convolution`.

Reproducibility (R). `python examples/polyphase_filterbank.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.842 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_signals_polyphase_filterbanks.py`, `tests/test_block4_hardening.py`, `tests/test_block15_polyphase_refinement.py` and 2 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `70c0560838804d81cfc22326f2b4ef37d611aba24d57c4a3709197b860e050ab`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
polyphase channels: (4, 4, 4, 4)
filtered length: 18
packet tree nodes: 15
```

EX-E-037. Portable jet snapshot and tamper rejection

Source and placement. `komorebi-math/examples/portable_nonlinear_state.py`. Chapters 43 and 61, portable nonlinear state. Local claim: `EX-E-037-CONTRACT`.

Input (I). Diagonal order-2 tensor entries 3,-2; x/xx jet; directions (2,5),(-1,4).

Hypotheses and evidence class (H). NUMERICAL snapshot / INTEGRITY check. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Capture and serialize a jet, restore it, require a comparison certificate, then replace the payload digest with 64 zeroes.

Expected result (O). One stored coefficient; evaluation (-6,0); the tampered payload is rejected with ValidationError.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-III-D58`.

Failure boundary (F). The shipped digest replacement is an executed negative control. Digest integrity does not establish callback semantics outside the captured finite jet.

Source API routes. `komorebi_math.PacketSystem`, `komorebi_math.exceptions.ValidationError`, `komorebi_math.export.dumps_portable`, `komorebi_math.export.loads_portable`, `komorebi_math.export.portable_digest` and 3 more routes in the JSON ledger.

Reproducibility (R). `python examples/portable_nonlinear_state.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.806 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_generating_block13.py`, `tests/test_certificates_registry.py`, `tests/test_algorithms_complexity_benchmarks.py` and 71 more file in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `72aaebad93767495ffcb5bf2f22f97de2222e5a81b2daa0918fa56160bf96469`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
snapshot address: PacketJetAddress(output='x', inputs=('x', 'x'))
stored coefficients: 1
portable digest:
dae6206f9b99acfa72649825253fd0b748c1e62236109f0a120872767ad97033
evaluation: [(-6+0j), 0j]
tampered payload: rejected
```

EX-E-038. Discrete precision and task scheduling

Source and placement. `komorebi-math/examples/precision_schedule.py`. Chapter 30, precision scheduling. Local claim: `EX-E-038-CONTRACT`.

Input (I). Two two-choice dtype groups with costs 1 or 3 and quantized errors (3,0),(2,0); budget 3; analyze/low/high/synthesize task DAG.

Hypotheses and evidence class (H). EXACT finite model / supplied duration assumptions. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the chosen-precision certificate, then compute an unlimited-resource schedule for the fixed dependencies and durations.

Expected result (O). Choose (low64,high32), cost 4, makespan 5 and critical path (analyze,high,synthesize).

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VIII-T28`.

Failure boundary (F). A cyclic dependency graph or infeasible precision budget is not a valid schedule. This is not a measured parallel speedup.

Source API routes. `komorebi_math.algorithms.DTypeChoice`, `komorebi_math.algorithms.Task`, `komorebi_math.algorithms.assign_discrete_precisions`, `komorebi_math.algorithms.schedule_unlimited`.

Reproducibility (R). `python examples/precision_schedule.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.808 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_algorithms_precision.py`, `tests/test_algorithms_scheduling.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `fb4ee131cb7b5081a0984974d4d51010824312bfbafbd2e52f36da44a5f6e27a`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
precision choices ('low64', 'high32')
total cost 4.0
schedule makespan 5.0
critical path ('analyze', 'high', 'synthesize')
```

EX-E-039. Prime-power kernels and valuations

Source and placement. `komorebi-math/examples/prime_power_generating.py`. Chapter 24, prime-power generating systems. Local claim: `EX-E-039-CONTRACT`.

Input (I). Prime 3, exponent 5, power 2, binomial indices 137 and 52; Bell input (137,5,9); q-binomial input (48,22,2,5).

Hypotheses and evidence class (H). EXACT integer/modular arithmetic. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compare the kernel residue with Python integer comb modulo 3^5, require the Bell reduction and compute the q-valuation.

Expected result (O). Kernel residue 81, valuation 4, Bell digit sum 5 and q-binomial valuation 1.

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). Invalid primes or negative exponents must be rejected; residues do not identify the full integer value.

Source API routes. `komorebi_math.generating.PrimePowerKernelCompiler`, `komorebi_math.generating.generalized_bell_digit_reduction`, `komorebi_math.generating.q_binomial_valuation_decomposition`.

Reproducibility (R). `python examples/prime_power_generating.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 2.057 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_generating_cartier_padic.py`, `tests/test_generating_domains.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `992082ab5f90e3f77cfc7b899e10844e7fea09cc5519e8a9588c75136b70423b`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'kernel_residue': 81, 'kernel_valuation': 4, 'bell_digit_sum': 5,
'q_binomial_valuation': 1}
```

EX-E-040. Finite DSP pipeline with fixed seed

Source and placement. `komorebi-math/examples/production_dsp.py`. Chapters 31 through 36 and 66, production DSP. Local claim: `EX-E-040-CONTRACT`.

Input (I). Seed 1212; 1024 samples at 1024 Hz with a 73 Hz sinusoid; finite FIR, resampling 5/4, NLMS and wavelet fixtures.

Hypotheses and evidence class (H). NUMERICAL finite DSP / OBSERVATIONAL risk. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require STFT, streaming filters, resampling, adaptive and wavelet certificates, then report finite output sizes and an observed denoising comparison.

Expected result (O). Dominant frequency 73 Hz; 1280 resampled values, 1027 convolution values, learned weights approximately (0.7,-0.35,0.15). Denoising improves on this seeded fixture only.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 11 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 12 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `KM-DSP-C02`, `KM-DSP-C04`, `KM-DSP-D02`, `KM-DSP-D07`, `KM-DSP-D10` (the complete set is in the execution record).

Failure boundary (F). Do not equate batch and streaming frame counts with different framing contracts: this fixture prints 33 and 29 respectively.

Source API routes. `komorebi_math.signals.certified_overlap_add_convolve`, `komorebi_math.signals.cross_spectrum`, `komorebi_math.signals.denoising_risk_certificate`, `komorebi_math.signals.design_biquad`, `komorebi_math.signals.design_lowpass` and 10 more routes in the JSON ledger.

Reproducibility (R). `python examples/production_dsp.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. NumPy default_rng(1212).

Runtime and filesystem. Recorded Linux replay: 0.949 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block12_recursive_fft.py`, `tests/test_block12_windows_time_frequency.py`, `tests/test_block12_denoise_streaming.py` and 2 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `4a0928bb7048e62417efbba97f90fd0f4ba78c4fd4018338b23ee0adfb1bf376`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{
  "adaptive_final_weights": [
    0.7,
    -0.35,

```

EX-E-041. Amplitude damping and finite error correction

Source and placement. `komorebi-math/examples/quantum_channel_qec.py`. Chapters 54 through 55, channels and error correction. Local claim: `EX-E-041-CONTRACT`.

Input (I). Damping parameter 0.2; excited qubit; the three-qubit repetition-code projector and identity plus three single-X errors.

Hypotheses and evidence class (H). NUMERICAL finite quantum algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the channel certificate, compare the output density diagonal, then require Knill-Laflamme and recovered-channel certificates.

Expected result (O). The excited-state diagonal becomes (0.2,0.8); the declared finite error set is correctable by the supplied recovery.

Certificate and replay checks (C). The source contains 1 explicit `assert` statement and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VII-T31`, `PSC-VII-T42`, `PSC-VII-T44`.

Failure boundary (F). Correcting this error set does not certify arbitrary errors. Parameters outside the channel domain must fail.

Source API routes. `komorebi_math.quantum.QuantumCode`, `komorebi_math.quantum.amplitude_damping`.

Reproducibility (R). `python examples/quantum_channel_qec.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.873 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_quantum_channels_qec.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `c7d4831611607d0e208ba02f1422ee08dfa3100c8a50c64dec975bb13cdc6e6a`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
quantum channel and error correction example passed
```

EX-E-042. Interfering symmetry-resolved circuit paths

Source and placement. `komorebi-math/examples/quantum_symmetry_circuit.py`. Chapters 53 through 54, symmetry circuits. Local claim: `EX-E-042-CONTRACT`.

Input (I). Z symmetry, cyclic order 2, three Hadamard gates and four matching packet systems; initial state (1,0).

Hypotheses and evidence class (H). NUMERICAL finite quantum circuit. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require reconstruction and block-unitarity certificates and evaluate the declared packet interference report.

Expected result (O). Target probability is 1/2 within numerical tolerance. Coherent path amplitudes, not independent path probabilities, are combined.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 3 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-VII-C17`, `PSC-VII-T14`, `PSC-VII-T15`.

Failure boundary (F). Replacing coherent addition with a probability sum would discard interference and is not the implemented contract.

Source API routes. `komorebi_math.quantum.CircuitPacketExpansion`, `komorebi_math.quantum.cyclic_symmetry_projectors`.

Reproducibility (R). `python examples/quantum_symmetry_circuit.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.855 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_quantum_symmetry_circuits.py`, `tests/test_quantum_channels_qec.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `7f5e976cd4255999aace0e6edd359120b57c0d0249b82c17989152404056f8a7`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
quantum circuit example passed 0.4999999999999998
```

EX-E-043. First packet-resolved operator program

Source and placement. `komorebi-math/examples/quickstart.py`. Chapter 4, first verified program. Local claim: `EX-E-043-CONTRACT`.

Input (I). Four-cycle shift matrix, seed e0, even/odd diagonal projectors and a UnifiedSystem.

Hypotheses and evidence class (H). NUMERICAL finite matrix algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Construct seed and packet systems, resolve operator blocks and print the system summary and block norms.

Expected result (O). The summary is valid, the seed hull dimension is 4 and the off-diagonal block norms are sqrt(2); diagonal block norms vanish.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`.

Failure boundary (F). The seed hull is this finite generated span; it is not a universal claim of minimal generators for arbitrary algebras.

Source API routes. `komorebi_math.PacketOperator`, `komorebi_math.PacketSystem`, `komorebi_math.SeedSystem`, `komorebi_math.UnifiedSystem`.

Reproducibility (R). `python examples/quickstart.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.795 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_operators_transfer.py`, `tests/test_nonlinear_trees.py`, `tests/test_morphisms.py` and 16 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `7d844580b57e0fccd5a923a78570d7265797c8dcbf39ad5bc31ce81b5f9e844a`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'valid': True, 'exactness': 'numerical', 'grammar_vertices': (),
'seed_dimension': 4, 'packet_names': ('even', 'odd'), 'operators':
('shift',), 'refinement_levels': 0, 'metadata': {}}
hull dimension: 4
block norms: ((0.0, 1.4142135623730951), (1.4142135623730951, 0.0))
```

EX-E-044. Finite ramification with an unmet realization gate

Source and placement. `komorebi-math/examples/ramification_completion.py`. Chapter 58, ramification and completion. Local claim: `EX-E-044-CONTRACT`.

Input (I). Prime-2 alternating form and quadratic refinement, two declared ramification stages, and five Boolean completion gates with realization=False.

Hypotheses and evidence class (H). EXACT finite data / CONDITIONAL external gates. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Build the ramification report and inspect the conditional completion result.

Expected result (O). Breaks (0,1), dimensions (4,2), Arf invariant 0, completion_ready=False and unmet gate realization.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). A successful script must retain completion_ready=False. The four supplied true gates are assumptions, not newly proven global theorems.

Source API routes. `komorebi_math.langlands.completion.AutomorphicCompletionReport`, `komorebi_math.langlands.completion.CompletionGate`, `komorebi_math.langlands.completion.GateStatus`, `komorebi_math.langlands.local.AlternatingForm`, `komorebi_math.langlands.local.QuadraticRefinement` and 3 more routes in the JSON ledger.

Reproducibility (R). `python examples/ramification_completion.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.940 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_local_heisenberg_symplectic.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `3d7343488c3c849ddcd61bfb02c531a3a6b07ad0c13ab1d4e989073d0045d279`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'ramification_breaks': (0, 1), 'ramification_dimensions': (4, 2),
'arf_invariant': 0, 'completion_ready': False, 'unmet_gates':
('realization',)}
```

EX-E-045. Recurrence lanes and modular large-index terms

Source and placement. `komorebi-math/examples/recurrence_packets.py`. Chapters 18 and 26, recurrence packets. Local claim: `EX-E-045-CONTRACT`.

Input (I). Fibonacci recurrence, modulus-7 lane at address 3, twelve lane terms; index 1,000,000 modulo 1,000,003; period modulo 32.

Hypotheses and evidence class (H). EXACT integer/modular recurrence. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the finite lane certificate, then evaluate a modular term and finite period.

Expected result (O). The lane begins 2,55,1597; the large-index residue is 3 and the period modulo 32 is 48.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-IX-T43`.

Failure boundary (F). The lane modulus and the arithmetic reduction modulus have different roles and must not be interchanged.

Source API routes. `komorebi_math.arithmetic.fibonacci_recurrence`.

Reproducibility (R). `python examples/recurrence_packets.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.878 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_arithmetic_recurrence.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `6c4852b544e9aabb96d69e94125e593d7a4b662493593f4f0129bb1ef062a344`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
packet (2, 55, 1597, 46368, 1346269, 39088169, 1134903170, 32951280099,
956722026041, 27777890035288, 806515533049393, 23416728348467685)
F(1_000_000) mod 1_000_003 3
period mod 32 48
```

EX-E-046. Recurrence bridge and state observability

Source and placement. `komorebi-math/examples/recurrence_state_coordinate_atlas.py`. Chapter 18, recurrence state coordinates. Local claim: `EX-E-046-CONTRACT`.

Input (I). Sixteen Pell values mapped to Tribonacci defect coordinates; a third-order SISO system with the shipped exact A,B,C,D and state (2,-3,5).

Hypotheses and evidence class (H). EXACT finite rational state-space algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Check the sequence-coordinate bridge, require controllability-coordinate equivalence and invert the observability map.

Expected result (O). The bridge preserves finite coordinates and the observable state is (-9,-15,-6).

Certificate and replay checks (C). The source contains 2 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `CC.R3`.

Failure boundary (F). Finite defect coordinates do not assert that the Pell sequence obeys the homogeneous Tribonacci recurrence.

Source API routes. `komorebi_math.coordinates.certify_state_coordinate_change`, `komorebi_math.coordinates.controllability_coordinate_transform`, `komorebi_math.coordinates.get_recurrence_model`, `komorebi_math.coordinates.observability_coordinate_transform`, `komorebi_math.coordinates.sequence_coordinates_between_models` and 1 more route in the JSON ledger.

Reproducibility (R). `python examples/recurrence_state_coordinate_atlas.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.919 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Source SHA-256. `f54912ebd67030bf03f20630f33de3f9fcedd5cda7135679a0f5b2c37bc1fa5d`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
recurrence bridge: Pell recurrence coordinates of length 16 -> Tribonacci
recurrence coordinates of length 16
observable state coordinates: (Fraction(-9, 1), Fraction(-15, 1),
Fraction(-6, 1))
```

EX-E-047. Packet refinement, CRT and weighted transfer

Source and placement. `komorebi-math/examples/refinement_pipeline.py`. Chapters 12 through 14, refinement pipeline. Local claim: `EX-E-047-CONTRACT`.

Input (I). Two coarse and four fine coordinate projectors, vector (1,2,3,4), residue modulus 3 and CRT pairs (1 mod 2,2 mod 3,4 mod 5).

Hypotheses and evidence class (H). EXACT indexing/weights / NUMERICAL inversion. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Refine/coarsen, reconstruct residue data, solve CRT and verify the acyclic weighted-transfer inverse against a dense inverse.

Expected result (O). Two refinement levels, CRT residue 29 and minimum path weight 3 from packet 0 to 2.

Certificate and replay checks (C). The source contains 5 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-II-C11`, `PSC-II-T03`.

Failure boundary (F). Cyclic transfer graphs do not automatically admit the same finite acyclic inverse formula.

Source API routes. `komorebi_math.PacketRefinement`, `komorebi_math.PacketSystem`, `komorebi_math.WeightedTransferEdge`, `komorebi_math.WeightedTransferGraph`, `komorebi_math.refinement.RefinementTower` and 2 more routes in the JSON ledger.

Reproducibility (R). `python examples/refinement_pipeline.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.831 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_operators_transfer.py`, `tests/test_nonlinear_trees.py`, `tests/test_morphisms.py` and 18 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `122868a33c99ee2b334f141e876540d07ff40b71354f649e16523a77ea1115ce`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
refinement levels: 2
CRT address: 29
minimum transfer weight 0 to 2: 3
```

EX-E-048. Pause, resume and verify a finite jet stream

Source and placement. `komorebi-math/examples/resumable_packet_jet_stream.py`. Chapter 43, resumable jet streaming. Local claim: `EX-E-048-CONTRACT`.

Input (I). Order-2 tensor [[[1,2],[3,4]]], full source/target packets, directions (2,3),(-1,4), chunk size 1 and initial evaluation budget 2.

Hypotheses and evidence class (H). NUMERICAL finite stream / INTEGRITY checks. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Capture a partial stream, resume it, verify chunk digests and require the streamed evaluation certificate inside a temporary directory.

Expected result (O). Pause after two evaluations, resume=True, four chunks, four stored coefficients and value 53. The temporary stream directory is deleted on exit.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 5 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-III-D60`.

Failure boundary (F). Tampered or incompatible stream chunks must be rejected. The captured finite snapshot is not a serialized arbitrary callback.

Source API routes. `komorebi_math.PacketSystem`, `komorebi_math.nonlinear.PacketJetFamily`, `komorebi_math.nonlinear.PolynomialDerivativeProvider`, `komorebi_math.nonlinear.capture_packet_jet_stream`, `komorebi_math.nonlinear.open_packet_jet_snapshot_stream`.

Reproducibility (R). `python examples/resumable_packet_jet_stream.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.926 seconds, measured under the shared reference profile; this is not a performance promise. The script owns a TemporaryDirectory for its kmstream and deletes it on normal exit. The runner retains logs and metadata, not the temporary stream.

Related package tests. `tests/test_block10_sparse_autodiff.py`, `tests/test_operators_transfer.py`, `tests/test_nonlinear_trees.py` and 16 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `15c78001b6938920535c006a8c968dd8cda75a49ae029ea673acd80aca276cc8`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```

  "value": [
    53.0
```

EX-E-049. Sparse derivative plan with backend disclosure

Source and placement. `komorebi-math/examples/scalable_nonlinear.py`. Chapters 37 through 43, scalable nonlinear execution. Local claim: `EX-E-049-CONTRACT`.

Input (I). Exact rational two-output derivative data with four stored entries versus ten dense entries, x/y packets and fixed rational directions.

Hypotheses and evidence class (H). EXACT declared input / NUMERICAL packet realization. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compile and execute sparse support, round-trip a jet snapshot and inspect CuPy availability without demanding a GPU execution.

Expected result (O). Two active and six pruned blocks, two derivative calls and reconstructed derivative (-4,-36). GPU status is diagnostic and must not be counted as a CUDA pass.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 4 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 6 output/artifact predicates with exit code zero and 245 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-III-A10`, `PSC-III-C08`, `PSC-III-D58`.

Failure boundary (F). Exact coefficient inputs do not by themselves imply that all intermediate NumPy packet operations remain exact.

Source API routes. `komorebi_math.Exactness`, `komorebi_math.PacketSystem`, `komorebi_math.export.dumps_portable`, `komorebi_math.export.loads_portable`, `komorebi_math.nonlinear.PacketJetFamily` and 7 more routes in the JSON ledger.

Reproducibility (R). `python examples/scalable_nonlinear.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.787 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_nonlinear_correction_elimination.py`, `tests/test_generating_block13.py`, `tests/test_block10_sparse_autodiff.py` and 21 more file in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `3279dfc545c0828f2ac84306e9db3ecb35277c3371f8518ac7d7b068d204c687`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
sparse entries: 4
dense entries: 10
active packet blocks: 2
pruned packet blocks: 6
provider derivative calls: 2
reconstructed derivative: (np.complex128(-4+0j), np.complex128(-36+0j))
snapshot coefficients: 1
portable bytes: 6806
```

EX-E-050. Sparse packet-jet runtime counts

Source and placement. `komorebi-math/examples/scalable_nonlinear_runtime.py`. Chapter 43, nonlinear runtime. Local claim: `EX-E-050-CONTRACT`.

Input (I). Three-dimensional tensor with x^2, xz and z^2 entries; three coordinate packets; directions (2,-1,1/2),(-1/4,3,4).

Hypotheses and evidence class (H). NUMERICAL derivative evaluation / EXACT counts. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require sparse-storage, support, plan and evaluation certificates and report the declared finite execution counts.

Expected result (O). Three stored versus 27 dense entries; four active and 23 pruned blocks; four planned versus 27 naive calls; result (-1,-11.8125,8).

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 4 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 7 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-I-T20`, `PSC-III-A10`, `PSC-III-C08`, `PSC-III-D04P`.

Failure boundary (F). Pruning requires complete certified support, not merely absence from a sampled address list.

Source API routes. `komorebi_math.PacketSystem`, `komorebi_math.nonlinear.PacketJetFamily`, `komorebi_math.nonlinear.PolynomialDerivativeProvider`, `komorebi_math.nonlinear.SparsePolynomialDerivativeProvider`, `komorebi_math.nonlinear.compile_packet_jet_plan` and 2 more routes in the JSON ledger.

Reproducibility (R). `python examples/scalable_nonlinear_runtime.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.822 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_block10_sparse_autodiff.py`, `tests/test_operators_transfer.py`, `tests/test_nonlinear_trees.py` and 16 more files in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `78874af6b3b667359f0482e72731c929dc8d8d2461a188cf8989afb9f846777c`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
stored derivative entries: 3
dense derivative entries: 27
active packet blocks: 4

EX-E-051. Declared sequence models and compiler strategies

Source and placement. `komorebi-math/examples/sequence_compiler.py`. Chapter 26, sequence compiler. Local claim: `EX-E-051-CONTRACT`.

Input (I). Built-in Fibonacci, Thue-Morse and Apery sequence specifications; twelve terms each.

Hypotheses and evidence class (H). EXACT finite sequence execution. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Compile each declared model, require the compilation certificate and print its strategy and prefix.

Expected result (O). Strategies are declared linear recurrence, declared finite automaton and declared holonomic recurrence. Fibonacci ends the 12-term prefix at 89.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). The compiler uses supplied models here. This is not an experiment in autonomous discovery of an unknown recurrence.

Source API routes. `komorebi_math.sequences.apery_sequence`, `komorebi_math.sequences.compile_sequence`, `komorebi_math.sequences.fibonacci_sequence`, `komorebi_math.sequences.thue_morse_sequence`.

Reproducibility (R). `python examples/sequence_compiler.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.936 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `10fe1ba2019775f48f935659f010283b161557f80e63cd783cbaf7004869a143`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Fibonacci declared linear recurrence (0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55,
89)
Thue Morse declared finite automaton (0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0, 1)
Apery declared holonomic recurrence (Fraction(1, 1), Fraction(5, 1),
Fraction(73, 1), Fraction(1445, 1), Fraction(33001, 1), Fraction(819005, 1),
 Fraction(21460825, 1), Fraction(584307365, 1), Fraction(16367912425, 1),
Fraction(468690849005, 1), Fraction(13657436403073, 1),
Fraction(403676083788125, 1))
```

EX-E-052. Separated jumps and retained reconstruction

Source and placement. `komorebi-math/examples/singular_packet_recovery.py`. Chapter 36, singular packet recovery. Local claim: `EX-E-052-CONTRACT`.

Input (I). 513 samples on a 512-cell grid; jumps at 0.23,0.71 with amplitudes 0.45,-0.35; sinusoidal background with declared Lipschitz bound 0.08*pi and zero noise.

Hypotheses and evidence class (H). NUMERICAL finite sampling / stated separation hypotheses. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require separated-jump recovery, build the singular packet and certify an identity retained-reconstruction operator.

Expected result (O). Detected cells are (117,363), estimated locations approximately (0.22949219,0.70996094). Location errors are within one grid cell; amplitude errors obey the finite smooth-background bound.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-V-T18`, `PSC-V-T36`.

Failure boundary (F). The Lipschitz and separation hypotheses are supplied. The identity reconstruction is not evidence of compression or recovery under arbitrary noise.

Source API routes. `komorebi_math.signals.SingularPacket1D`, `komorebi_math.signals.recover_separated_jumps`, `komorebi_math.signals.retained_packet_reconstruction`.

Reproducibility (R). `python examples/singular_packet_recovery.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.825 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_signals_recovery.py`, `tests/test_signals_wavelets_singular.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `5f11bb3142a0b715562bbbd8d07935885214ee42b60d204b717d53faa3655f3c`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
detected cells: (117, 363)
estimated locations: [0.22949219 0.70996094]
estimated amplitudes: [ 0.45006308 -0.35012219]
```

EX-E-053. Fourier, Haar and exact residue ordering

Source and placement. `komorebi-math/examples/spectral_packet_coordinates.py`. Chapters 19 and 32, spectral packet coordinates. Local claim: `EX-E-053-CONTRACT`.

Input (I). Eight samples arange(8), normalized DFT and Haar transforms, and an exact modulus-2 residue permutation.

Hypotheses and evidence class (H). NUMERICAL spectral transforms / EXACT permutation. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require spectral transform certificates, invert both numerical transforms and round-trip the exact residue ordering.

Expected result (O). The residue order is (0,2,4,6,1,3,5,7); Fourier and Haar reconstruct the input to tolerance.

Certificate and replay checks (C). The source contains 3 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 1 output/artifact predicate with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `CC.S1`, `CC.S4`.

Failure boundary (F). Tiny complex residuals in Fourier coordinates are numerical roundoff, not nonzero exact invariants.

Source API routes. `komorebi_math.coordinates.discrete_fourier_transform`, `komorebi_math.coordinates.haar_wavelet_transform`, `komorebi_math.coordinates.residue_class_transform`.

Reproducibility (R). `python examples/spectral_packet_coordinates.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.933 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_coordinates_general_persistence.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `d72f667e04cca2940e0fcc064faf36a01e98f58c373d3f32e18148a85bf38be4`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
Fourier coordinates: [ 9.89949494+0.00000000e+00j
-1.41421356+3.41421356e+00j
 -1.41421356+1.41421356e+00j -1.41421356+5.85786438e-01j
 -1.41421356-1.21233848e-15j -1.41421356-5.85786438e-01j
 -1.41421356-1.41421356e+00j -1.41421356-3.41421356e+00j]
Haar coordinates: [ 9.89949494 -5.65685425 -2.         -2.
-0.70710678 -0.70710678
 -0.70710678 -0.70710678]
residue-lane order: (Fraction(0, 1), Fraction(2, 1), Fraction(4, 1),
Fraction(6, 1), Fraction(1, 1), Fraction(3, 1), Fraction(5, 1), Fraction(7,
1))
```

EX-E-054. Standard-window and affine Mahler refinement

Source and placement. `komorebi-math/examples/standard_window_mahler.py`. Chapter 25, standard-window Mahler models. Local claim: `EX-E-054-CONTRACT`.

Input (I). Prime 7, compression 2, address 3 and degree 12; values n^4+2n+1 for n=0,…,8; affine change n -> 3n+2.

Hypotheses and evidence class (H). EXACT polynomial/Mahler algebra. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the finite standard-window certificate, form a Mahler series from the exact values and evaluate eight refined terms.

Expected result (O). Window period 3; refined values start 21,636,4113,14664 and end at 279888 for the eight-term prefix.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 1 syntactic `.require()` call site. These are source counts, not dynamic proof counts. The installed-wheel run passed 3 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-IX-T09`.

Failure boundary (F). A finite interpolation model is not an arbitrary infinite-sequence continuation without its polynomial hypothesis.

Source API routes. `komorebi_math.arithmetic.MahlerSeries`, `komorebi_math.arithmetic.StandardWindow`.

Reproducibility (R). `python examples/standard_window_mahler.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.786 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_mahler_polyphase.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `3ae534dd9fa2f50a2d9d4b6b79bd2cdc91c12f266acd683d948f51a32c4c87ca`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
period 3
window (1, 6, 5, 2, 6, 5, 2, 6, 5, 2, 6, 5, 2)
refined (Fraction(21, 1), Fraction(636, 1), Fraction(4113, 1),
Fraction(14664, 1), Fraction(38445, 1), Fraction(83556, 1), Fraction(160041,
 1), Fraction(279888, 1))
```

EX-E-055. Preconditioned conjugate gradient

Source and placement. `komorebi-math/examples/structured_krylov.py`. Chapters 29 through 30, structured Krylov methods. Local claim: `EX-E-055-CONTRACT`.

Input (I). The shipped symmetric positive-definite 4-by-4 matrix, right-hand side (1,2,3,4), layout (2,2) and relative tolerance 1e-12.

Hypotheses and evidence class (H). NUMERICAL linear solve. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require the block-Jacobi certificate, solve with preconditioned CG and require its convergence certificate.

Expected result (O). Four iterations on this fixture and a residual below 1e-10.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 2 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 2 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-VIII-T22`, `PSC-VIII-T24`.

Failure boundary (F). A convergence certificate must not be inferred from an iteration cap alone; indefinite matrices violate CG assumptions.

Source API routes. `komorebi_math.algorithms.PacketLayout`, `komorebi_math.algorithms.block_jacobi_certificate`, `komorebi_math.algorithms.block_jacobi_preconditioner`, `komorebi_math.algorithms.conjugate_gradient`.

Reproducibility (R). `python examples/structured_krylov.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.940 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_algorithms_complexity_benchmarks.py`, `tests/test_algorithms_discovery_gpu.py`, `tests/test_algorithms_krylov.py` and 1 more file in the shared-import crosswalk. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `7b1259b89df76c0498535fc3dfba37ba5c8166cbff8e4424e021d366aa354f3b`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
iterations 4
residual 9.930136612989092e-16
```

EX-E-056. Finite tame and Heisenberg packets

Source and placement. `komorebi-math/examples/tame_heisenberg.py`. Chapter 57, tame Heisenberg packets. Local claim: `EX-E-056-CONTRACT`.

Input (I). Frobenius q=2, degree 3, exponent 1; Heisenberg prime 3 and rank 1; two explicitly given group elements.

Hypotheses and evidence class (H). FINITE exact group data / NUMERICAL matrix representation. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Require orbit, tame relation, group-law and selector certificates.

Expected result (O). Orbit (1,2,4), tame and Heisenberg dimensions 3, determinant orientation 1 and selector rank 1.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 4 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Observed base-certificate identifiers include `PSC-XI-HEISENBERG-LAW`, `PSC-XI-ISOTROPIC-SELECTOR`, `PSC-XI-TAME-ATOM`, `PSC-XI-TAME-ORBIT`.

Failure boundary (F). Finite packet relations do not establish a global Langlands correspondence.

Source API routes. `komorebi_math.langlands.local.FrobeniusOrbit`, `komorebi_math.langlands.local.HeisenbergModel`, `komorebi_math.langlands.local.TameWeilPacket`.

Reproducibility (R). `python examples/tame_heisenberg.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.780 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_local_heisenberg_symplectic.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `319d3d92a3187ec81723b6a2d80f0a0a3fc6d2b83f9dd6c53b04251fb966b0a2`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{'frobenius_orbit': (1, 2, 4), 'tame_dimension': 3,
'determinant_orientation': (1+0j), 'heisenberg_dimension': 3,
'selector_rank': 1}
```

EX-E-057. Typed operator relation certificate

Source and placement. `komorebi-math/examples/typed_grammar.py`. Chapters 9 and 50, typed grammars. Local claim: `EX-E-057-CONTRACT`.

Input (I). One object X of dimension 3, generator T and relation T^3-T=0; realization T=diag(-1,0,1).

Hypotheses and evidence class (H). NUMERICAL finite matrix relation. The source fixture fixes all remaining literals and dimensions. The first observed certificate for each identifier, including checked and unchecked assumptions, is retained in the execution record.

Actions (A). Build the typed relation and print its numerical certificate.

Expected result (O). Certificate valid=True, relation count 1, cubic residual 0 and theorem identifier PSC-I-T01.

Certificate and replay checks (C). The source contains 0 explicit `assert` statements and 0 syntactic `.require()` call sites. These are source counts, not dynamic proof counts. The installed-wheel run passed 4 output/artifact predicates with exit code zero and 244 package modules checked for import origin.

Failure boundary (F). A dimension mismatch or realization that violates T^3=T must not receive a valid relation certificate.

Source API routes. `komorebi_math.OperatorGrammar`, `komorebi_math.OperatorRealization`.

Reproducibility (R). `python examples/typed_grammar.py`. Reference wheel, NumPy, and the logged validation environment with SciPy, SymPy and mpmath. Direct imports are listed separately; this profile is not a proof of minimal transitive dependencies. No random input in the shipped fixture.

Runtime and filesystem. Recorded Linux replay: 0.791 seconds, measured under the shared reference profile; this is not a performance promise. No persistent output files are declared by the example. Replay stdout/stderr and metadata are retained in the selected evidence directory.

Related package tests. `tests/test_unified_extensions_cli.py`, `tests/test_grammar_realization.py`. These files were included in the separate 1,203-test source run. Shared imports alone do not prove full behavioral coverage.

Source SHA-256. `92242b96f29d7e06fc35ad7059e03d9567bb20743940154189c0bc91db3a4df0`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

Observed output excerpt. Selected fields or wrapped lines only. Full stdout is preserved in the replay directory.

```
{
  "assumptions_checked": [
    "operator shapes",
    "typed path composition",
    "declared relations"
  ],
  "assumptions_unchecked": [],
  "diagnostics": {
```

E.3 PowerShell and historical records

EX-E-058. Scalable nonlinear workflow

Source and placement. `komorebi-math/examples/Test-KomorebiBlock10.ps1`. Chapters 63 and 71, scalable nonlinear CLI verification. Local claim: `EX-E-058-CONTRACT`.

Input (I). -Python (default python). Root is resolved from PSScriptRoot.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Runs sparse runtime and portable-state examples, strict research API validation, verify block10 and its deep audit.

Expected result (O). Both examples and all verifier children must report success.

Certificate and replay checks (C). Legacy workflow for the reference package; native PowerShell runtime has not been tested. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI api check --strict-signatures`, `CLI verify block10`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiBlock10.ps1`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Script-

s/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `bdedbcdf85ef86b804c67d58728879ee1f68066af9f50fa1a85e09bb189f81d7`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-059. Streaming and semantic workflow

Source and placement. `komorebi-math/examples/Test-KomorebiBlock11.ps1`. Chapters 63, 71, and 72, streaming and semantic verification. Local claim: `EX-E-059-CONTRACT`.

Input (I). -Python (default python). Root is resolved from PSScriptRoot.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Runs resumable streams, semantic profiling, golden fixtures, API checks, verify block11 and its deep audit.

Expected result (O). The stream resumes correctly, semantic counts match, and all verifier children succeed.

Certificate and replay checks (C). Legacy workflow for the reference package; native PowerShell runtime has not been tested. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI golden`, `CLI verify block11`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiBlock11.ps1`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Scripts/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `a8e89805f07e3e2c94082e908ee4d62666c34d1bfba3d6edc3ae875ca108222b`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-060. DSP workflow

Source and placement. `komorebi-math/examples/Test-KomorebiBlock12.ps1`. Chapters 63 and 71, DSP CLI verification. Local claim: `EX-E-060-CONTRACT`.

Input (I). No parameters. python must be on PATH. Run from the komorebi-math directory because the example path is relative.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Runs DSP verification and its aggregate suite, strict/beta API checks and production_dsp.py.

Expected result (O). Five child invocations must succeed; the DSP record must match its finite fixture contract.

Certificate and replay checks (C). Legacy workflow for the reference package; native PowerShell runtime has not been tested. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI verify dsp`, `CLI verify block12`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiBlock12.ps1`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Scripts/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `6609830bf08e1ea2d5bd19369be9a3139a4cdecc5c6ff86e988c8f69b9ca0729`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-061. Generating-function workflow

Source and placement. `komorebi-math/examples/Test-KomorebiBlock13.ps1`. Chapters 63 and 71, generating-function CLI verification. Local claim: `EX-E-061-CONTRACT`.

Input (I). No parameters. python on PATH; run from komorebi-math. The script hardcodes finite mask, Cartier, kernel and Bell parameters.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Runs generating-function verification and its aggregate suite, API checks, four generating commands and three generating examples.

Expected result (O). All verifier, CLI and example children must succeed. Cartier coefficients refer to a rational-mask Mahler series.

Certificate and replay checks (C). Legacy workflow for the reference package; native PowerShell runtime has not been tested. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI verify generating`, `CLI generating mask`, `CLI generating cartier`, `CLI generating kernel`, `CLI generating bell`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiBlock13.ps1`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Scripts/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `ea48d1edaec34a55d9c18cec97320577fa2a1634f4200ce001d458ff03ba8012`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-062. Coordinate workflow

Source and placement. `komorebi-math/examples/Test-KomorebiBlock14.ps1`. Chapters 63 and 74A, coordinate example with `--length` syntax. Local claim: `EX-E-062-CONTRACT`.

Input (I). -Python (default python); named coordinate fixtures and packet –length 12 –modulus 3.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Runs coordinate verification and its aggregate suite, coordinate catalog and eight coordinate operations, golden fixtures and API checks.

Expected result (O). All child commands must succeed. The packet invocation uses the corrected –length option, not –size.

Certificate and replay checks (C). Legacy workflow for the reference package; native PowerShell runtime has not been tested. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI verify coordinates`, `CLI coordinates packet`, `CLI coordinates model`, `CLI coordinates formal`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiBlock14.ps1`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Scripts/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `9fc18b1b97995c2864b1ba6c2cd7124b4413d715ad73d4680168f31e1b9e77c7`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-063. Nonlinear verification workflow

Source and placement. `komorebi-math/examples/Test-KomorebiBlock9.ps1`. Chapters 63 and 71, nonlinear CLI verification. Local claim: `EX-E-063-CONTRACT`.

Input (I). -Python (default python). Root is resolved from PSScriptRoot.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Runs jets, tree elimination, filtered transport, verify block9 and the nonlinear deep audit.

Expected result (O). All five child commands must succeed independently.

Certificate and replay checks (C). Legacy workflow for the reference package; native PowerShell runtime has not been tested. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI verify block9`, `verification/block9_deep_audit.py`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiBlock9.ps1`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Script-

s/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `a53bcd528b9293e2c5f840f150d0886beca7501b4ba90578e2dcaca4873c6623`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-064. Historical aggregate runner

Source and placement. `komorebi-math/examples/Test-KomorebiEverything.ps1`. Chapters 63 and 71, historical aggregate verification. Local claim: `EX-E-064-CONTRACT`.

Input (I). Modes Quick/Full/Maximum; -Python defaults to py. Other switches control system-site dependencies, offline wheelhouse/network, optional AD/CUDA/build checks, retained work and results directory.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Searches specifically for the 0.16.0a2 wheel/source distribution and optional historical Git bundle, then orchestrates that release workflow.

Expected result (O). In the reference delivery, the required historical artifacts are absent. This script is not the reference release gate. The reference delivery uses VERIFY_REPAIR.ps1.

Certificate and replay checks (C). Historical, not applicable as a reference release check; not executed. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The fixed 0.16.0a2 artifact lookup prevents use as a reference release gate. Do not remove this version guard merely to obtain a green exit.

Source API routes. `historical CLI verify block16`, `historical release 0.16.0a2`.

Reproducibility (R). `Historical record only: do not run as the R2 release gate.`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Scripts/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `178283fd02310695b18ad69733b8b36f381bc08d8c15977eeafdce23bdbcad4b`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

EX-E-065. Windows wheel installation and export workflow

Source and placement. `komorebi-math/examples/Test-KomorebiExport.ps1`. Chapters 59 through 60 and 63, export CLI verification. Local claim: `EX-E-065-CONTRACT`.

Input (I). The `-Wheel` argument is required. `-Python` defaults to `python`, and `-OutputDirectory` defaults to `.\komorebi_export_test`. The optional switches are `UseSystemSitePackages`, `NoDependencies` and `SkipPdf`.

Hypotheses and evidence class (H). ORCHESTRATION evidence, not a mathematical exactness class. Requires the native PowerShell interpreter and the paths, dependencies and source release explicitly named by the script. A Linux reconstruction of child commands is not a native PowerShell qualification.

Actions (A). Creates a Windows-layout virtual environment, installs the supplied wheel, runs export/LaTeX CLIs, writes sequence and sample reports and prints SHA-256 hashes.

Expected result (O). Current wheel installation plus nonempty matching JSON/CSV/Markdown/HTML/TeX and ZIP outputs are required. PDF paths are conditional on SkipPdf and compiler availability.

Certificate and replay checks (C). Windows-specific virtual-environment paths; native runtime not executed. Native acceptance requires individual child exit codes, expected outputs/artifacts and a deliberate failing-child control. No success is claimed by the static inventory.

Failure boundary (F). The script does not explicitly test LASTEXITCODE after every native command. ErrorActionPreference alone is not treated here as a fail-closed native-child gate. Inspect each child result; inject a nonzero Python exit during native qualification.

Source API routes. `CLI export sequence`, `CLI export json`, `CLI export bundle`, `CLI latex compile`, `komorebi_math.export.export_data`.

Reproducibility (R). `powershell -NoProfile -File examples/Test-KomorebiExport.ps1 -Wheel release/dist/komorebi_math-1.0.0b4-2-py3-none-any.whl`. Native PowerShell, installed Python and required package dependencies. Export additionally expects Windows Scripts/python.exe and Scripts/komorebi.exe; optional LaTeX enables PDFs. No top-level deterministic seed. Child scripts retain their own declared seeds.

Runtime and filesystem. Not measured; workflow may run multiple verification suites or build/install operations. komorebi-math repository directory. Export output must be disposable; historical Everything must use a separate matching 0.16.0a2 archive. The individual verification wrappers primarily produce console output. Export retains its environment and exports. Historical Everything owns a results/work directory and applies its own cleanup policy; it is not executed here.

Source SHA-256. `ae4682c36e744a1b4f3d90be8df0f2d2e99859c1bb9ed395c27b852b317c83a3`. Full source and replay hashes are also stored in the JSON ledger and per-record result files.

E.4 Coverage and qualification boundaries

The record/source bijection covers **65 of 65 scripts** and all record anchors are unique. The recorded Python replay covers **57 of 57 default invocations**. The recorded full-source suite passed 1,203 tests and the separate record/contract suite passed 134 tests. These results describe the unchanged reference package and scripts.

Appendix E's documentation-record layer is complete. Its all-platform execution predicate is not: seven reference native PowerShell workflows remain unexecuted, and the historical aggregate is explicitly not applicable to the reference package. Optional GPU/device observations do not establish CUDA qualification. The replay checks default invocations, not every possible argument combination, input size or backend.

Appendix F provides the complete CLI option matrix for this reference baseline. Strict HTML validation, native Windows qualification, and the final publication predicate require their own evidence.

Appendix F. Complete CLI option matrix

Using the command reference. Begin with the command record for your task, read its argument table, and then inspect its output, file effects, and failure contract. The smallest invocation is a starting point using the prepared fixtures; it may depend on files created in Section F.1. For a conceptual introduction to command-line use, read Chapter 63 first.

A short command workflow.

1. Select the Python interpreter containing the package and dependencies you intend to use. The `python -m komorebi_math` form makes that selection explicit.
2. Inspect help for the exact command or subcommand you need. Compare it with this version-bound record before reusing a script with another release.
3. Read the argument types and defaults. Distinguish a switch from an option that consumes a value, and distinguish an input path from an output path.
4. Prepare the stated input files and choose a new output location when the command writes files. The replacement rules differ by command.
5. After the command finishes, inspect the exit status and diagnostics as well as any result or certificate. A file can exist after a failed run.

The fixture helper in F.1 is distributed with the source material used for the recorded replay. It is not an installed CLI subcommand. If you have only the wheel, obtain the corresponding source fixtures or prepare equivalent inputs according to the selected command's contract. Do not copy a fixture pathname without first creating the file it names.

Common command-line difficulties.

Symptom	First check
An option is reported as unrecognized	Confirm the command group, the installed version, and the exact full option spelling in that command's help. Options are not automatically global.
A negative list is treated as another option	Use the attached-value form illustrated in F.0, such as `--values=-1,0,1`.
A matrix argument is split by the shell	Quote the complete value, including semicolon-separated rows.
Parsing succeeds but the operation rejects the input	Read the semantic boundary: parser types do not enforce every mathematical precondition.
An output path already exists	Check this command's replacement policy and select a fresh path before requesting an overwrite.
A JSON response or output file exists but the run failed	Inspect the exit status, stderr, and the response's validation or certificate fields.
A verification command reports an unavailable GPU or unmet gate	Read the qualification requirement and the recorded scope; an expected rejection is not a qualified platform.

Use the suite-dispatch table in F.2 when choosing verification. The name `all` has a specific recorded dispatch target and should not be read as every possible test in the repository. Similarly, shared export flags can have different effects on different formats. The per-command semantic boundary explains what is actually consumed and produced.

F.0 Scope, syntax and evidence

The parser, commands, source locations, and outcomes below are the recorded reference-baseline inventory. They preserve the complete documented interface and do not assert that later package revisions expose identical commands or have been replayed here.

This reference covers every leaf reachable from the reference package's installed `komorebi` parser: **46 commands, 201 non-help argument records and 51 verification-suite names**. There are **57 parser nodes**, including the root and command groups. The 201 count repeats shared export options at each consuming command. It is not a count of 201 distinct flag spellings. With each leaf's help action included, the ledger has 247 argument records.

The installed console command `komorebi` and `python -m komorebi_math` dispatch to the same CLI. The latter is used below to select the intended interpreter. The only root option is `-h` / `--help`; there is no global `--version`, `--json` or `--force`. Run `info` for the version. Every command and group supports help. A bare root or group requires a subcommand and exits with code 2.

Defaults and token rules. Not supplied means the Python default is `None`, not the string `None`. Boolean store-true flags default to false and consume no following value. The reference parser permits unambiguous long-option abbreviations and repeated scalar options take their last value; use full flags in maintained scripts. Parser type conversion is not mathematical domain validation. An accepted integer can still be rejected by the implementation.

Shell quoting. Quote comma-separated values and especially semicolon-separated matrix rows in both shells. Attach a leading-negative list to its option, for example `--values=-1,0,1`, because quoting alone does not stop argparse from treating a leading hyphen as an option. Commands shown below use one-line syntax valid in either POSIX or PowerShell. Native PowerShell execution is not claimed. Inspect `$LASTEXITCODE` in PowerShell and `$?` immediately after a POSIX command. Do not infer success from the presence of a JSON file.

Exit and failure contract. Help exits 0. Missing arguments, unknown options, conflicting tiers and invalid parser types/choices exit 2 with usage on stderr. Domain handlers typically return 0 for success and 1 for rejected validation or failed certificates. Some commands explicitly return 2 for semantic errors. There is no global exception-to-JSON adapter: uncaught errors can terminate with code 1 and a traceback. The individual records name their boundaries. Filesystem permissions and unexpected backend failures are not promised to have a uniform JSON schema.

Evidence classes. Parser reflection establishes syntax coverage. CLI replay establishes the recorded finite behavior. A certificate's exactness field still controls its mathematical scope. Caller-supplied completion gates remain assumptions. A successful expected-rejection test is never counted as successful platform qualification.

Traceability. `Block38_CLI_Inventory.json` contains the full parser tree, per-action metadata, mutually exclusive groups, handler line ranges and source hashes. `Block38_CLI_Records.json` adds semantics. `Block38_Runtime_Selectors.json` binds runtime aliases. `Block38_CLI_Output_Shapes.json` retains observed nested field/type structures, not a universal or closed JSON Schema for every possible result.

F.1 Local fixture preparation

Use a scratch directory outside the source tree. The following helper creates the small JSON, array, TeX and stream fixtures used by the examples, and refuses existing fixture paths unless explicitly forced. It also creates a deliberately corrupted stream for rejection tests. No network access is used.

```
python tools/block38/fixtures.py --output-dir cli-scratch
cd cli-scratch
```

Run the helper from the extracted bundle root, with the reference wheel installed in that interpreter. `input.json` contains columns x=[1,2] and y=[3,4]. `array.json` contains [1,2,3]. `small.tex` is a minimal local document. `complete.kmstream` is a four-coefficient finite quadratic stream. `partial.kmstream` contains its committed prefix. `bad.kmstream` deliberately fails chunk integrity. Commands with output paths assume those paths do not already exist.

Optional YAML export requires PyYAML. PDF commands require a working local LaTeX installation. NumPy binary export requires a suitable numeric representation: the reference NPY command uses `array.json`, not the column dictionary. Optional GPU checks cannot qualify CUDA on a CPU-only host. Run only trusted TeX and installed plugins: disabling shell escape or detecting an extension is not a general execution sandbox.

F.2 Runtime selectors and the verification dispatch matrix

`verify` accepts the following exact suite strings. The second column is the function selected by the reference dispatcher. The result is the recorded host exit, not an all-input proof. Several suites aggregate or repeat earlier suites, so check totals must not be summed as unique mathematics.

Suite	Dispatched function	Observed result
`core`	`run_core_verification`	exit 0
`refinement`	`run_refinement_verification`	exit 0
`nonlinear`	`run_nonlinear_verification`	exit 0
`block2`	`run_block2_verification`	exit 0
`algorithms`	`run_algorithms_verification`	exit 0
`block3`	`run_block3_verification`	exit 0
`signals`	`run_signals_verification`	exit 0
`dynamics`	`run_dynamics_verification`	exit 0
`block4`	`run_block4_verification`	exit 0
`analytic`	`run_analytic_verification`	exit 0
`quantum`	`run_quantum_verification`	exit 0
`block5`	`run_block5_verification`	exit 0
`arithmetic`	`run_arithmetic_verification`	exit 0
`sequences`	`run_sequences_verification`	exit 0
`block6`	`run_block6_verification`	exit 0
`deformation`	`run_deformation_verification`	exit 0
`langlands-local`	`run_langlands_local_verification`	exit 0
`langlands-finite-image`	`run_langlands_finite_image_verification`	exit 0
`langlands-completion`	`run_langlands_completion_verification`	exit 0
`langlands`	`run_langlands_verification`	exit 0
`block7`	`run_block7_verification`	exit 0
`export`	`run_export_verification`	exit 0
`block8`	`run_block8_verification`	exit 0
`block9`	`run_block9_verification`	exit 0
`hardening`	`run_scalable_nonlinear_verification`	exit 0
`block10`	`run_block10_verification`	exit 0
`streaming-beta`	`run_streaming_beta_verification`	exit 0
`block11`	`run_block11_verification`	exit 0
`dsp`	`run_dsp_verification`	exit 0
`block12`	`run_block12_verification`	exit 0
`generating`	`run_generating_verification`	exit 0
`block13`	`run_block13_verification`	exit 0
`coordinates`	`run_coordinates_verification`	exit 0
`block14`	`run_block14_verification`	exit 0
`block15`	`run_block15_verification`	exit 0
`stable`	`run_stable_verification`	exit 0
`release`	`run_release_qualification_verification`	exit 0
`gpu`	`run_gpu_verification`	exit 1; CUDA unqualified
`block16`	`run_block16_verification`	exit 0
`upgrade`	`run_upgrade_verification`	exit 0
`evidence`	`run_evidence_verification`	exit 0
`documentation`	`run_documentation_verification`	exit 0
`beta`	`run_beta_readiness_verification`	exit 0
`block17`	`run_block17_verification`	exit 0
`frame-algebra`	`run_frame_algebra_verification`	exit 0

Suite	Dispatched function	Observed result
`block18`	`run_block18_verification`	exit 0
`integration`	`run_integration_verification`	exit 0
`block19`	`run_block19_verification`	exit 0
`expression`	`run_expression_verification`	exit 0
`block20`	`run_block20_verification`	exit 0
`all`	`run_block17_verification`	exit 0

Reference aggregate-verification alias. `verify all` is exactly `run_block17_verification`. It does not select the source pytest suite or automatically include frame-algebra, integration, expression or their later aggregate extensions. To check those installed extensions explicitly, use:

```
python -m komorebi_math verify block18
python -m komorebi_math verify block19
python -m komorebi_math verify block20
```

Sequence names. `apery`, `bell`, `bernoulli`, `catalan`, `euler`, `fibonacci`, `lucas`, `motzkin`, `partition`, `thue-morse`, `zigzag`. Strip whitespace, convert to lowercase, replace underscores with hyphens, then apply the alias map. Aliases: `apery-zeta3` -> `apery`, `euler-zigzag` -> `zigzag`, `signed-euler` -> `euler`, `thue-morse` -> `thue-morse`, `thuemorse` -> `thue-morse`.

Polynomial families. `monomials`, `Euler polynomials`, `Fibonacci polynomials`, `falling factorials`, `rising factorials`, `binomial polynomials`, `Bernoulli polynomials`, `Lucas polynomials`, `Pell polynomials`, `Chebyshev T polynomials`, `Chebyshev U polynomials`, `Legendre polynomials`, `probabilists Hermite polynomials`, `physicists Hermite polynomials`, `Laguerre polynomials`. Convert to lowercase, retain only alphanumeric characters, then apply the alias map. Short aliases map to normalized catalog keys:

Alias	Normalized target
`bernoulli`	`bernoullipolynomials`
`binomial`	`binomialpolynomials`
`chebyshevt`	`chebyshevtpolynomials`
`chebyshevu`	`chebyshevupolynomials`
`euler`	`eulerpolynomials`
`falling`	`fallingfactorials`
`fibonacci`	`fibonaccipolynomials`
`hermitephysicists`	`physicistshermitepolynomials`
`hermiteprobabilists`	`probabilistshermitepolynomials`
`laguerre`	`laguerrepolynomials`
`legendre`	`legendrepolynomials`
`lucas`	`lucaspolynomials`
`monomial`	`monomials`
`pell`	`pellpolynomials`
`rising`	`risingfactorials`

Recurrence models. `Fibonacci`, `Lucas`, `Pell`, `Jacobsthal`, `Tribonacci`, `Padovan`. Convert to lowercase, retain only alphanumeric characters, and match the six catalog names.

Completion gate names. `residual`, `patching`, `comparison`, `fiber`, `realization`. `--satisfied` uses a comma-separated list. Supplying all five marks external flags as supplied, not proved. Unknown names return 2.

Export selectors. `json`, `yaml`, `csv`, `tsv`, `text`, `markdown`, `html`, `latex`, `pdf`, `npy`, `npz`. Explicit aliases: `md` -> `markdown`, `tex` -> `latex`, `txt` -> `text`, `yml` -> `yaml`.

Suffix	Inferred format
`.csv`	`csv`
`.htm`	`html`
`.html`	`html`
`.json`	`json`
`.markdown`	`markdown`
`.md`	`markdown`
`.npy`	`npy`
`.npz`	`npz`
`.pdf`	`pdf`
`.tex`	`latex`
`.tsv`	`tsv`
`.txt`	`text`
`.yaml`	`yaml`
`.yml`	`yaml`

F.3 Shared export option group

The following 16 options occur on `export sequence`, `export standard-window`, `export euler`, `export json` and `export bundle`. Each command's JSON record contains the full expanded list. The per-command tables below avoid printing these shared rows five times. Accepted options can have format-specific or handler-specific effects; an accepted flag is not necessarily consumed by every route.

Option	Type and requirement	Default	Accepted values
`--output`	str; required	`no default`	runtime domain; see semantics
`--format`	str; optional	`not supplied`	runtime domain; see semantics
`--title`	str; optional	`'Komorebi Math Export'`	runtime domain; see semantics
`--author`	str; optional	`not supplied`	runtime domain; see semantics
`--date`	str; optional	`not supplied`	runtime domain; see semantics
`--abstract`	str; optional	`not supplied`	runtime domain; see semantics
`--document-class`	str; optional	`'article'`	runtime domain; see semantics
`--toc`	switch; optional	`False`	on/off flag
`--mathjax`	switch; optional	`False`	on/off flag
`--engine`	str; optional	`'auto'`	auto, pdflatex, xelatex, lualatex, latexmk
`--passes`	int; optional	`2`	runtime domain; see semantics
`--timeout`	float; optional	`120.0`	runtime domain; see semantics
`--keep-auxiliary`	switch; optional	`False`	on/off flag
`--no-keep-tex`	switch; optional	`False`	on/off flag
`--no-type-metadata`	switch; optional	`False`	on/off flag
`--force`	switch; optional	`False`	on/off flag

`--output`. Required destination path. Parent creation and existence checks are handled by the export writer. Use a fresh path unless replacement is intended.

`--format`. Runtime format name or alias; None means infer from extension. On export bundle this singular option is unused; use –formats.

`--title`. Document title for generic data/document construction. export sequence constructs its own sequence title.

`--author`. Optional author passed to the document constructor. It is metadata, not an authenticated signature.

`--date`. Optional displayed document date, not a build timestamp attestation. Not propagated by the export sequence handler.

`--abstract`. Optional document abstract. Not propagated by the export sequence handler.

`--document-class`. LaTeX document class string, validated by LatexRenderOptions. Mainly relevant to LaTeX/PDF.

`--toc`. Request a LaTeX table of contents. No effect on non-LaTeX formats.

`--mathjax`. Include the HTML MathJax loader. Rendering that HTML can require a network-accessible script; CLI export itself writes local text.

`--engine`. Select a PDF compiler; auto resolves an available engine. Merely parsing the option does not verify a compiler exists.

`--passes`. Positive integer direct-compiler pass count; compiler options are constructed even when exporting another format.

`--timeout`. Positive per-compiler-process timeout in seconds. Does not cap sequence generation, serialization or the entire CLI run.

`--keep-auxiliary`. Keep LaTeX auxiliary files after a successful render.

`--no-keep-tex`. Do not retain the TeX companion when the exporter uses that option for PDF export.

`--no-type-metadata`. Set preserve_types=False in serialization options. This can change encoded structure and is not a portable round-trip guarantee.

`--force`. Permit replacement of an existing export destination. It does not supply automatic rollback or guarantee atomic updates.

A LaTeX document-class name must match `[A-Za-z0-9_.-]+`. Compiler passes and timeout must be positive. The CLI constructs render/compiler option objects even for non-PDF exports, so invalid option values can fail before a format-specific writer is reached. Explicit export formats override suffix inference. A requested output file stores the rendered payload, whereas stdout normally stores an export acknowledgment. `--no-type-metadata` affects the exported representation, not necessarily the acknowledgment printed by the CLI.

Overwrite caution. Most export destinations and optional release-report outputs refuse an existing path without `--force`. Companion files and multi-step operations are not a general atomic transaction. `latex compile` is the important exception: it has no force guard and can overwrite existing PDF/log artifacts. Use a new directory for repeatable runs.

F.4 Output contracts and schema boundaries

JSON records below name all emitted top-level keys seen in the bounded fixtures and give their types. Conditional fields are explained in the command-specific contract. Nested structures and variant observations are retained in the machine-readable output-shape ledger. Those observations are examples of the versioned Python serializers, not a replacement for the portable codec contract in Appendix G. Environment maps, diagnostics, source paths and residuals can vary by run.

The common certificate object has `valid:boolean`, `exactness:string`, `assumptions_checked:array`, `assumptions_unchecked:array`, `diagnostics:object`, `message:string`, `residuals:object`, `theorem_id:string or null` and `tolerance:number or null`. A certificate may be the whole stdout object or a nested field. Qualification uses `certificate.valid`, and its stdout has no top-level `passed` field. Export and LaTeX result serializers can include `__type__`. Rational values may be strings; spectral complex numbers use `{real:number, imag:number}`.

The report path acknowledgment from `api snapshot` is not the manifest itself. Similarly, export stdout is not the exported data. `sequence --index` switches to a scalar line rather than a prefix JSON object. A failed command may

emit a valid rejection report, only stderr, or a traceback. Consumers must inspect exit status and the appropriate report field together.

F.5 Complete command records

All records include handler location in `src/komorebi_math/cli/main.py`, exact argument defaults, output behavior, overwrite policy and a minimum fixture invocation. Commands that have no mathematical inputs still have records. The common `-h` / `--help` action is available on every record and is documented once in F.0.

F.5.1 `info`

Record CLI-F-001. Prints the installed distribution version and a textual capability summary.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi info [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. Human-readable text, not a stable JSON object.

Semantic boundary. The phrase implemented blocks is explanatory metadata, not a build or proof audit.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math info
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Observed text excerpt. Only the first five lines are shown.

```
komorebi-math 1.0.0b4
language: seed -> address -> operate -> project -> transfer -> refine -> constrain -> complete -> reconstruct
implemented blocks: finite dimensional core through Block 17, production finite DSP, plus research-tier Blocks
   ↪ 18-20 for frame algebra, finite integration, and typed exact expressions
```

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 80-84, handler `command_info`. Handler SHA-256: `48e1f485 7b08efac42af0fdf96cc1c296d8d39a32a5e01355e7ee52c220c1ac0`.

F.5.2 `doctor`

Record CLI-F-002. Inspects available backends, optional import specifications, LaTeX executables and extension entry points.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi doctor [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. Human-readable environment listing. Returns 0 when all discovered extensions load, otherwise 1.

Semantic boundary. Available or installed means detection, not numerical/device qualification. Extension discovery can import third-party plugins.

File effects and replacement. No output-file option. Plugin discovery can run third-party extension import code; no general no-side-effects promise is made for installed plugins.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math doctor
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Observed text excerpt. Only the first five lines are shown.

```
Python: 3.13.5
Platform: Linux-6.18.35-x86_64-with-glibc2.41
Backends:
  numpy    available
  sympy    available
```

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 87-106, handler `command_doctor`. Handler SHA-256: `4b7395aa701ef6c667695555c1c70a437ba027b7d58c8e959d2a96f8630f5544`.

F.5.3 features

Record CLI-F-003. Prints registered feature keys, statuses and summaries.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi features [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. Aligned text rows: feature key, status value and summary.

Semantic boundary. Planned and implemented status labels are retained. Listing is not a runtime test.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math features
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Observed text excerpt. Only the first five lines are shown.

```
algorithms              implemented               Packet IR, structured operators, low rank algebra, support
    ↪ propagation, Krylov methods, precision planning, exact tree compilation, scheduling, restricted discovery,
    ↪ and optional CuPy execution.
analytic                implemented               Cyclic projections, transfer and signed sections, reciprocal and
    ↪ Appell families, numerical zero strings, Hadamard products, and zeta diagnostics.
arithmetic              implemented               Modular domains, Hurwitz modes, standard windows, odd and dyadic
    ↪ Euler coordinates, Mahler transfer, polyphase refinement, local unit gains, and recurrence packets.
backends                partial                    NumPy and optional exact SymPy backends are implemented. A CuPy
    ↪ packet executor is available when CuPy is installed.
coordinates             implemented               Arbitrary exact bases and atlases, checked finite
    ↪ analysis--synthesis systems, normalized-series changes, recurrence defects, companion and state-space
    ↪ coordinates, classical polynomial-family connections, combinatorial transforms, affine and formal charts,
    ↪ tensor and operator transport, finite-field maps, spectral transforms, packet permutations, trusted
    ↪ persistence, and named bridges such as Euler-to-Fibonacci.
```

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 109-111, handler `command_features`. Handler SHA-256: `6c054eaab8e6f1fe796725a05601870dd0d156f1ad8d9d24e06a03e1bc6befd0`.

F.5.4 `verify`

Record CLI-F-004. Invokes exactly one installed verification-suite function and prints each check plus a summary.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi verify [-h]
    {core, refinement, nonlinear, block2, algorithms, block3, signals, dynamics, block4,
    analytic, quantum, block5, arithmetic, sequences, block6, deformation,
    langlands-local, langlands-finite-image, langlands-completion, langlands, block7,
    export, block8, block9, hardening, block10, streaming-beta, block11, dsp, block12,
    generating, block13, coordinates, block14, block15, stable, release, gpu, block16,
    upgrade, evidence, documentation, beta, block17, frame-algebra, block18, integration,
    block19, expression, block20, all}
```

Argument	Type and requirement	Default	Accepted values
`suite`	str; required	`no default`	51 exact suite names; see F.2

Output and exit contract. Text lines [PASS] or [FAIL], optional detail, then the certificate message. 0 means the selected report passed, 1 means it failed.

Semantic boundary. The all choice dispatches to run_block17_verification, not the full pytest suite or the later redundant-frame, finite-integration, and typed-expression aggregate suites. Suite names are listed in F.2.

File effects and replacement. No persistent output-file option. Selected suites may use temporary files or optional backend probes.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math verify core
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 52 associated replay cases are retained, including shared-suite selections or variants where applicable.

Observed text excerpt. Only the first five lines are shown.

```
[PASS] typed grammar relations
[PASS] finite seed hull
[PASS] packet analysis and synthesis
[PASS] packet operator reconstruction
[PASS] packet path expansion
```

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `KeyError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 114-178, handler `command_verify`. Handler SHA-256: `64ca9c5c0367b49a2748ab739ba90389b5d93ee5064e4ecf8bdbcde3524843f8`.

F.5.5 `api check`

Record CLI-F-005. Compares a supplied or committed manifest against the installed research, beta or stable API.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi api check [-h] [--manifest MANIFEST] [--strict-signatures]
    [--beta | --stable]
```

Argument	Type and requirement	Default	Accepted values
`--manifest`	str; optional	`not supplied`	runtime domain; see semantics
`--strict-signatures`	switch; optional	`False`	on/off flag
`--beta`	switch; optional	`False`	on/off flag
`--stable`	switch; optional	`False`	on/off flag

Mutually exclusive flags. `--beta` and `--stable` cannot be supplied together.

Output and exit contract. API compatibility JSON report including certificate, compatible, added, removed, kind_changed, signature_changed, reference_digest, current_digest and strict_signatures. 0 means compatible, 1 means incompatible or handled validation failure.

Semantic boundary. Default tier is research. –beta and –stable are mutually exclusive. –strict-signatures affects the research route; beta/stable use their own strict policies. –manifest is an input, never an output.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math api check
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`added`	array (empty in this fixture)
`certificate`	object
`compatible`	boolean
`current_digest`	string
`kind_changed`	array (empty in this fixture)
`reference_digest`	string
`removed`	array (empty in this fixture)
`signature_changed`	array (empty in this fixture)
`strict_signatures`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 181-200, handler `command_api_check`. Handler SHA-256: `174af0d3e1428da632539550eaf1b7761028e8b47393353bf91a1a826202496a`.

F.5.6 `api snapshot`

Record CLI-F-006. Creates a current API manifest for the selected tier and writes it to –output.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi api snapshot [-h] --output OUTPUT [--force] [--beta |
    --stable]
```

Argument	Type and requirement	Default	Accepted values
`--output`	str; required	`no default`	runtime domain; see semantics
`--force`	switch; optional	`False`	on/off flag
`--beta`	switch; optional	`False`	on/off flag
`--stable`	switch; optional	`False`	on/off flag

Mutually exclusive flags. `--beta` and `--stable` cannot be supplied together.

Output and exit contract. JSON acknowledgment with path:string and digest:string. The file contains the API manifest, not this acknowledgment.

Semantic boundary. Default tier is research. –beta and –stable cannot be combined. Refuses an existing path unless –force is present.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math api snapshot --output api.json
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 5 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`digest`	string
`path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 203-225, handler `command_api_snapshot`. Handler SHA-256: `3e22829fdb745d15031c840ef3f3514c4506375ca872b47ae06f89fd61087f02`.

F.5.7 `golden`

Record CLI-F-007. Executes the committed finite behavioral fixture.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi golden [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON object containing cases/results and certificate. 0 means all fixture checks passed, otherwise 1.

Semantic boundary. A finite behavioral fixture is not a claim that all inputs or all theorems are verified.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math golden
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`fixture_digest`	string
`fixture_path`	string
`results`	array[object

Field	Type at this invocation

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 228-239, handler `command_golden`. Handler SHA-256: `59c88298c63c8fe9d336046071b896dd01708f27172c58cb733a7023aa2621e7`.

F.5.8 `release contract`

Record CLI-F-008. Checks the committed current-beta release contract.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release contract [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON release report with checks, passed and certificate. 0/1 follows report.passed.

Semantic boundary. Checks an installed frozen contract. It does not certify the outer documentation ZIP or its editorial edition.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release contract
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`checks`	array[object]
`contract`	object
`contract_digest`	string
`passed`	boolean
`runtime`	object

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 242-249, handler `command_release_contract`. Handler SHA-256: `7def743048b70cf34a9264d94d8e1f0a72ba1471abca4c3b66e7bb772142c0e8`.

F.5.9 `release environment`

Record CLI-F-009. Prints the current finite runtime record.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release environment [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON environment object. Recorded keys and nested types are retained in the output-shape ledger.

Semantic boundary. A runtime record is descriptive; exit 0 does not mean all optional packages, platforms or hardware passed qualification.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release environment
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`environment`	object
`package_version`	string
`platform`	string
`python`	string
`python_executable`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 252-258, handler `command_release_environment`. Handler SHA-256: `482c880da9c20aa759ce7013e2860b02569a20966a3b0dd83d4edb411d7cb64e`.

F.5.10 `release qualify`

Record CLI-F-010. Runs installed freeze-candidate qualification; optionally writes the full report.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release qualify [-h] [--gpu] [--require-gpu] [--output OUTPUT]
    [--force]
```

Argument	Type and requirement	Default	Accepted values
`--gpu`	switch; optional	`False`	on/off flag
`--require-gpu`	switch; optional	`False`	on/off flag

Argument	Type and requirement	Default	Accepted values
`--output`	str; optional	`not supplied`	runtime domain; see semantics
`--force`	switch; optional	`False`	on/off flag

Output and exit contract. JSON qualification report with checks, gpu, gpu_required, optional_backends, runtime, schema, schema_version, version and certificate. There is no top-level passed field; use certificate.valid. The same full report is written when –output is set.

Semantic boundary. –require-gpu implies a GPU probe and requires success; –gpu alone probes opportunistically. Output overwrite rejection is raised by report.write and is not caught at the CLI boundary.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release qualify
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`checks`	array[object]
`gpu`	null
`gpu_required`	boolean
`optional_backends`	object
`runtime`	object
`schema`	string
`schema_version`	integer
`version`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 261-273, handler `command_release_qualify`. Handler SHA-256: `d08d543517da3278c8561dc6be69e9415defabde14a0c9caaaac9c52aac98faa`.

F.5.11 `release upgrade`

Record CLI-F-011. Checks predecessor API, semantic, codec and portable-record upgrade contracts.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release upgrade [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON report with checks, passed and certificate. Returns 0/1 according to report.passed.

Semantic boundary. Only the committed predecessor contracts and records are covered. This is not an automatic source or installed-package upgrade.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release upgrade
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`checks`	array[object]
`contract`	object
`contract_digest`	string
`loaded_fixtures`	array[string]
`passed`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 292-299, handler `command_release_upgrade`. Handler SHA-256: `3df02aa760167edb3b3c0c4a1d93e45b2c9c2d9affa697f3dd5a3a910c7d7332`.

F.5.12 `release evidence`

Record CLI-F-012. Checks digest-bound platform evidence and can write a copy of the evidence report.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release evidence [-h] [--current] [--output OUTPUT] [--force]
```

Argument	Type and requirement	Default	Accepted values
`--current`	switch; optional	`False`	on/off flag
`--output`	str; optional	`not supplied`	runtime domain; see semantics
`--force`	switch; optional	`False`	on/off flag

Output and exit contract. JSON platform-evidence report with passed, certificate and coverage/missing-platform fields. A handled output-path rejection prints a diagnostic to stderr and returns 1.

Semantic boundary. –current requires current-version evidence across every declared platform family. Baseline evidence passing does not imply –current passes.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release evidence
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`covered_platforms`	array[string]
`current_platforms`	array[string]
`evidence`	object
`evidence_digest`	string
`inherited_records`	array[string]
`missing_current_platforms`	array[string]
`missing_platforms`	array (empty in this fixture)
`passed`	boolean
`release_candidate_ready`	boolean
`require_current_all_platforms`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 302-317, handler `command_release_evidence`. Handler SHA-256: `bd6a100a37964c562fb5ec28a25e6aaf74ef2f8027c4626d6b984e35fb681029`.

F.5.13 `release documentation`

Record CLI-F-013. Checks exact stable-namespace documentation coverage in the installed package.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release documentation [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON documentation report with changed, deprecated, extra, missing, current_digest, reference_digest, passed and certificate. Returns 0/1 by report.passed.

Semantic boundary. This is the stable package documentation gate, not a claim that the full manual, its supplementary crosswalks, or a strict MkDocs build is complete.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release documentation
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`changed`	array (empty in this fixture)
`current_digest`	string
`deprecated`	array (empty in this fixture)
`extra`	array (empty in this fixture)
`missing`	array (empty in this fixture)
`passed`	boolean
`reference_digest`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 320-327, handler `command_release_documentation`. Handler SHA-256: `65935e554a078b3237618e38da25f6683127a1d1c17adbeb6763cc3fc702cd1e`.

F.5.14 `release readiness`

Record CLI-F-014. Evaluates public-beta readiness or the stricter final/current-platform gate.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi release readiness [-h] [--final] [--gpu] [--require-gpu]
    [--output OUTPUT] [--force]
```

Argument	Type and requirement	Default	Accepted values
`--final`	switch; optional	`False`	on/off flag
`--gpu`	switch; optional	`False`	on/off flag
`--require-gpu`	switch; optional	`False`	on/off flag
`--output`	str; optional	`not supplied`	runtime domain; see semantics
`--force`	switch; optional	`False`	on/off flag

Output and exit contract. JSON readiness report with checks, passed and certificate, optionally copied to –output.

Semantic boundary. –final requires current-version platform evidence. –require-gpu implies –gpu and requires the hardware gate. A passing baseline is not a final-platform qualification.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math release readiness
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`certificate`	object
`checks`	array[object]
`gpu`	null
`mode`	string
`passed`	boolean
`runtime`	object
`version`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 330-347, handler `command_release_readiness`. Handler SHA-256: `8313a6c12b50403c4cd9b4e96606ccb5733f34534349ec5262e441f78e4392fc`.

F.5.15 `stream inspect`

Record CLI-F-015. Reads a packet-jet stream directory and emits its manifest.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi stream inspect [-h] [--allow-incomplete] [--verify-chunks]
    path
```

Argument	Type and requirement	Default	Accepted values
`path`	str; required	`no default`	runtime domain; see semantics
`--allow-incomplete`	switch; optional	`False`	on/off flag
`--verify-chunks`	switch; optional	`False`	on/off flag

Output and exit contract. JSON manifest, including state, completed coefficient count, chunks and stream digest. A rejected stream prints stderr and returns 1.

Semantic boundary. –allow-incomplete permits opening a partial stream; it does not declare completion. –verify-chunks adds chunk validation before printing. Inspection does not write or repair the stream.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math stream inspect complete.kmstream
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 5 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`capture_certificate`	object
`chunk_size`	integer
`chunks`	array[object]
`coefficients_completed`	integer
`evaluations_completed`	integer
`maximum_omitted_basis_norm`	number
`metadata`	object
`metadata_sha256`	string
`producer_version`	string
`state`	string
`stream_sha256`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 350-365, handler `command_stream_inspect`. Handler SHA-256: `aedc002a5cf0894af36728376237503c5627925be7143fbae437c84d56000397`.

F.5.16 `stream verify`

Record CLI-F-016. Opens a packet-jet stream and verifies every committed chunk.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi stream verify [-h] [--allow-incomplete] path
```

Argument	Type and requirement	Default	Accepted values
`path`	str; required	`no default`	runtime domain; see semantics
`--allow-incomplete`	switch; optional	`False`	on/off flag

Output and exit contract. Certificate JSON. Exit 0/1 follows certificate.valid or a handled stream validation error.

Semantic boundary. –allow-incomplete permits partial streams, so a valid committed prefix is not a completed full stream. No repair or write is performed.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math stream verify complete.kmstream
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 3 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`assumptions_checked`	array[string]
`assumptions_unchecked`	array[string]
`diagnostics`	object
`exactness`	string
`message`	string
`residuals`	object
`theorem_id`	string
`tolerance`	null
`valid`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 368-383, handler `command_stream_verify`. Handler SHA-256: `4b4b90a6a920fedfce4799a420885f4702218d56772aa719ae2462594436f254`.

F.5.17 `sequence`

Record CLI-F-017. Computes a finite prefix or one indexed exact sequence term.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi sequence [-h] [--terms TERMS] [--index INDEX]
    [--modulus MODULUS] [--compile]
    name
```

Argument	Type and requirement	Default	Accepted values
`name`	str; required	`no default`	runtime domain; see semantics
`--terms`	int; optional	`20`	runtime domain; see semantics
`--index`	int; optional	`not supplied`	runtime domain; see semantics
`--modulus`	int; optional	`not supplied`	runtime domain; see semantics
`--compile`	switch; optional	`False`	on/off flag

Output and exit contract. Prefix: JSON name:string, terms:array of strings; –compile adds strategy and exactness. With –index: a scalar text line, not the prefix object.

Semantic boundary. –index takes precedence over –terms. –modulus uses a compiled model even without –compile. Sequence names are normalized and aliases appear in F.2. Invalid names or domains can raise an uncaught exception.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math sequence fibonacci --terms 8
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 7 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`name`	string
`terms`	array[string]

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 396-419, handler `command_sequence`. Handler SHA-256: `713abaf159e30cb450b7b82774c3339bcb98f6dfd969e5d0f622763109cc3bda`.

F.5.18 `coordinates euler-fibonacci`

Record CLI-F-018. Constructs the exact signed-Euler recurrence-defect coordinates and their reconstruction.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates euler-fibonacci [-h] [--count COUNT]
```

Argument	Type and requirement	Default	Accepted values
`--count`	int; optional	`20`	runtime domain; see semantics

Output and exit contract. JSON system, count, initial, defects, reconstructed, homogeneous and defect_egf.

Semantic boundary. Exact quantities are rendered as rational strings where the serializer receives Fraction values. The finite count controls this calculation, not an infinite identity proof.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates euler-fibonacci --count 8
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`count`	integer
`defect_egf`	string
`defects`	array[string]
`homogeneous`	boolean
`initial`	array[string]
`reconstructed`	array[string]
`system`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 651-673, handler `command_coordinates_euler_fibonacci`. Handler SHA-256: `22c8daeeaf360fb2efa181517fb30d1f5c94ef36c3759c6e796ce20694c621f0`.

F.5.19 `coordinates recurrence`

Record CLI-F-019. Changes a supplied finite prefix between two exact recurrence-defect coordinate systems.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates recurrence [-h] --values VALUES --source SOURCE
    --target TARGET
    [--source-name SOURCE_NAME]
    [--target-name TARGET_NAME]
```

Argument	Type and requirement	Default	Accepted values
`--values`	str; required	`no default`	runtime domain; see semantics
`--source`	str; required	`no default`	runtime domain; see semantics
`--target`	str; required	`no default`	runtime domain; see semantics
`--source-name`	str; optional	`'source recurrence'`	runtime domain; see semantics
`--target-name`	str; optional	`'target recurrence'`	runtime domain; see semantics

Output and exit contract. JSON source_coordinates, target_coordinates, matrix, determinant:string and verified:boolean.

Semantic boundary. All three coefficient lists use comma-separated rational values. The mapped source coordinates are checked against independent target analysis before verified is emitted.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates recurrence --values '0,1,1,2,3,5' --source '1,1' --target '2,1'
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`determinant`	string
`matrix`	array[array[string]]
`source_coordinates`	array[string]
`target_coordinates`	array[string]
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 676-715, handler `command_coordinates_recurrence`. Handler SHA-256: `f695ca61720e3e1b5aec31b39f70f5e19313435a2db6583a4bc93dc2e8ed17e6`.

F.5.20 `coordinates catalog`

Record CLI-F-020. Lists built-in coordinate families, recurrence models and transform categories.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates catalog [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON category names mapped to arrays of descriptive names.

Semantic boundary. Use these names for runtime selectors where applicable; not every descriptive category is a direct CLI subcommand.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates catalog
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`affine_and_formal`	array[string]
`arithmetic`	array[string]
`combinatorial`	array[string]
`exact_linear`	array[string]

Field	Type at this invocation
`packet`	array[string]
`polynomial_families`	array[string]
`recurrence_models`	array[string]
`spectral`	array[string]
`state_space`	array[string]

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 743-785, handler `command_coordinates_catalog`. Handler SHA-256: `7ff9cc720866a2783e7ea47f2d04ec53af7aa5a6ecec3ccc67ee2049e5ef711e`.

F.5.21 `coordinates basis`

Record CLI-F-021. Connects exact finite bases supplied as matrices and optionally analyzes an ambient vector.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates basis [-h] --source-matrix SOURCE_MATRIX
    --target-matrix TARGET_MATRIX
    [--source-name SOURCE_NAME]
    [--target-name TARGET_NAME]
    [--vector VECTOR]
```

Argument	Type and requirement	Default	Accepted values
`--source-matrix`	str; required	`no default`	runtime domain; see semantics
`--target-matrix`	str; required	`no default`	runtime domain; see semantics
`--source-name`	str; optional	`'source basis'`	runtime domain; see semantics
`--target-name`	str; optional	`'target basis'`	runtime domain; see semantics
`--vector`	str; optional	`not supplied`	runtime domain; see semantics

Output and exit contract. JSON source, target, ambient_dimension, dimension, matrix, determinant, verified; –vector adds ambient_vector and both coordinate arrays.

Semantic boundary. Rows are separated by semicolons and entries by commas, but the basis vectors are columns. Quote the matrix token in both shells. Singular/incompatible bases and malformed rows are rejected.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.
