Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates basis --source-matrix '1,0;0,1' --target-matrix '1,1;0,1' --vector '3,2'
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 3 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`ambient_dimension`	integer
`ambient_vector`	array[string]
`determinant`	string
`dimension`	integer
`matrix`	array[array[string]]
`source`	string
`source_coordinates`	array[string]
`target`	string
`target_coordinates`	array[string]
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 788-821, handler `command_coordinates_basis`. Handler SHA-256: `56efd2a713babb6fe33f960f2ad3e1635fc94f95caa3657763d4d6838c8aa05c`.

F.5.22 `coordinates model`

Record CLI-F-022. Maps a sequence between named recurrence-model coordinates.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates model [-h] --source SOURCE --target TARGET
    [--count COUNT] [--values VALUES]
```

Argument	Type and requirement	Default	Accepted values
`--source`	str; required	`no default`	runtime domain; see semantics
`--target`	str; required	`no default`	runtime domain; see semantics
`--count`	int; optional	`12`	runtime domain; see semantics
`--values`	str; optional	`not supplied`	runtime domain; see semantics

Output and exit contract. JSON values, source, target, source_coordinates, target_coordinates, matrix and verified.

Semantic boundary. Without –values, generates –count values from the source model. With –values, that list is used and –count is ignored. Matching model names ignores case and nonalphanumeric characters.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates model --source Fibonacci --target Pell --count 6
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 2 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`matrix`	array[array[string]]
`source`	string
`source_coordinates`	array[string]
`target`	string
`target_coordinates`	array[string]
`values`	array[string]
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 824-852, handler `command_coordinates_model`. Handler SHA-256: `397e5daecd5663df8537a4cea573b6c7a2c92a382160916a1941b8d1a1b3e531`.

F.5.23 `coordinates polynomial`

Record CLI-F-023. Computes the exact connection matrix between graded polynomial families through a finite degree.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates polynomial [-h] [--source SOURCE]
    [--target TARGET] [--degree DEGREE]
```

Argument	Type and requirement	Default	Accepted values
`--source`	str; optional	`'euler'`	runtime domain; see semantics
`--target`	str; optional	`'fibonacci'`	runtime domain; see semantics
`--degree`	int; optional	8	runtime domain; see semantics

Output and exit contract. JSON degree, source, target, matrix, determinant:string and verified:boolean.

Semantic boundary. Runtime family names and aliases, not parser choices, determine acceptance. Degree controls a finite matrix. Unknown family or domain validation returns a handled failure.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates polynomial --degree 3
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`degree`	integer
`determinant`	string
`matrix`	array[array[string]]
`source`	string
`target`	string
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `ValidationError`.

Source binding. `src/komorebi_math/cli/main.py`, lines 718-740, handler `command_coordinates_polynomial`. Handler SHA-256: `c9c9aa21a244e2f79d4052dd687a69cf2f2faad988360e1f553897b3f4633a99`.

F.5.24 `coordinates combinatorial`

Record CLI-F-024. Builds one exact binomial, factorial or forward-difference transform.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates combinatorial [-h]
    --kind {binomial, inverse-binomial, forward-difference, monomial-to-falling,
    falling-to-monomial, monomial-to-rising, rising-to-monomial, rising-to-falling}
    --size SIZE [--values VALUES]
```

Argument	Type and requirement	Default	Accepted values
`--kind`	str; required	`no default`	binomial, inverse-binomial, forward-difference, monomial-to-falling, falling-to-monomial, monomial-to-rising, rising-to-monomial, rising-to-falling
`--size`	int; required	`no default`	runtime domain; see semantics
`--values`	str; optional	`not supplied`	runtime domain; see semantics

Output and exit contract. JSON kind, source, target, matrix, output:null or array and verified.

Semantic boundary. –size controls the transform size. Supplied –values must have that length. The eight parser choices are exhaustive for this command, not for the whole Python namespace.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates combinatorial --kind binomial --size 4 --values '1,2,3,4'
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 8 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`kind`	string
`matrix`	array[array[string]]
`output`	array[string]
`source`	string
`target`	string
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(KeyError, ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 855-896, handler `command_coordinates_combinatorial`. Handler SHA-256: `1760a255db3450ddb72a839f39517d2aa87680a747124dc8447072d3664c8652`.

F.5.25 `coordinates spectral`

Record CLI-F-025. Builds a finite Fourier, cosine, Hadamard or Haar coordinate transform.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates spectral [-h] --kind {dft, dct, hadamard, haar}
    --size SIZE [--values VALUES]
```

Argument	Type and requirement	Default	Accepted values
`--kind`	str; required	`no default`	dft, dct, hadamard, haar
`--size`	int; required	`no default`	runtime domain; see semantics
`--values`	str; optional	`not supplied`	runtime domain; see semantics

Output and exit contract. JSON kind, source, target, condition_number:number, matrix, output:null or array and verified. Complex entries are objects with real and imag numbers.

Semantic boundary. –values accepts real floating-point comma-separated data, not general rational fractions or complex tokens. Hadamard/Haar size restrictions are enforced by their constructors. Valid means numerical tolerance checks, not exact symbolic equality.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates spectral --kind dft --size 4 --values '1,2,3,4'
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`condition_number`	number
`kind`	string
`matrix`	array[array[object]]
`output`	array[object]
`source`	string
`target`	string
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(KeyError, ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 899-934, handler `command_coordinates_spectral`. Handler SHA-256: `b7169d9d9ad9b55968e3b10377bd25b92dc8742b4195e0905c4a4dee517fffdb`.

F.5.26 `coordinates packet`

Record CLI-F-026. Constructs an exact residue-lane, digit-reversal or Chinese-remainder permutation.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates packet [-h] --kind {residue, digit-reversal, crt}
    [--length LENGTH] [--modulus MODULUS]
    [--radix RADIX] [--moduli MODULI]
```

Argument	Type and requirement	Default	Accepted values
`--kind`	str; required	`no default`	residue, digit-reversal, crt
`--length`	int; optional	`8`	runtime domain; see semantics
`--modulus`	int; optional	`2`	runtime domain; see semantics
`--radix`	int; optional	`2`	runtime domain; see semantics
`--moduli`	str; optional	`'2,3'`	runtime domain; see semantics

Output and exit contract. JSON kind, source, target, matrix and verified.

Semantic boundary. residue uses –length/–modulus. digit-reversal uses –length/–radix. crt uses –moduli and ignores –length, –modulus and –radix. CRT dimension is derived from the moduli.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates packet --kind residue
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 3 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`kind`	string
`matrix`	array[array[string]]
`source`	string
`target`	string
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 937-965, handler `command_coordinates_packet`. Handler SHA-256: `f5404e9104d03ec87a54cde4d8c40c714d32a607a11f200607a8965e40702146`.

F.5.27 `coordinates formal`

Record CLI-F-027. Builds a truncated invertible formal change of variable and its inverse.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi coordinates formal [-h] --coordinate COORDINATE
    [--series SERIES] [--name NAME]
    [--source SOURCE] [--target TARGET]
```

Argument	Type and requirement	Default	Accepted values
`--coordinate`	str; required	`no default`	runtime domain; see semantics
`--series`	str; optional	`not supplied`	runtime domain; see semantics
`--name`	str; optional	`'formal coordinate change'`	runtime domain; see semantics
`--source`	str; optional	`'source formal coordinate'`	runtime domain; see semantics
`--target`	str; optional	`'target formal coordinate'`	runtime domain; see semantics

Output and exit contract. JSON name, source, target, coefficients, inverse, substitution_matrix, verified; –series adds pullback and roundtrip.

Semantic boundary. Use comma-separated rational coefficients. The coordinate must satisfy the constructor/inversion conditions, including the origin and invertible linear term. Labels do not change coefficients.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math coordinates formal --coordinate '0,1,1,0' --series '1,2,3,4'
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 3 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`coefficients`	array[string]
`inverse`	array[string]
`name`	string
`pullback`	array[string]
`roundtrip`	array[string]
`source`	string
`substitution_matrix`	array[array[string]]
`target`	string
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 968-1001, handler `command_coordinates_formal`. Handler SHA-256: `533d3f900f0ceac1c263481ff83f0ad20e8136ecaf5a5d9d91d67e77f211397e`.

F.5.28 `generating mask`

Record CLI-F-028. Compiles a finite Mahler mask into a carry plan and emits a finite sequence.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi generating mask [-h] --mask MASK --radix RADIX [--count COUNT]
```

Argument	Type and requirement	Default	Accepted values
`--mask`	str; required	`no default`	runtime domain; see semantics
`--radix`	int; required	`no default`	runtime domain; see semantics
`--count`	int; optional	`20`	runtime domain; see semantics

Output and exit contract. JSON radix, mask:array of strings, carry_bound, dimension, coefficients:array of strings and verified.

Semantic boundary. Mask entries are exact rationals and radix/count domains are checked by the compiler and certificate. A leading negative list should use –mask=-1,1 syntax so argparse receives one value.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math generating mask --mask '1,1' --radix 2 --count 8
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`carry_bound`	integer
`coefficients`	array[string]
`dimension`	integer
`mask`	array[string]
`radix`	integer
`verified`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 1004-1025, handler `command_generating_mask`. Handler SHA-256: `4c9b57c71ac7477d11fb9226c8e23edf907e00f5e797d088bf6e7330ca45033b`.

F.5.29 `generating cartier`

Record CLI-F-029. Compiles a rational Mahler mask modulo a prime into a Cartier linear representation.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi generating cartier [-h] --numerator NUMERATOR
    --denominator DENOMINATOR --prime PRIME
    [--count COUNT]
```

Argument	Type and requirement	Default	Accepted values
`--numerator`	str; required	`no default`	runtime domain; see semantics
`--denominator`	str; required	`no default`	runtime domain; see semantics
`--prime`	int; required	`no default`	runtime domain; see semantics
`--count`	int; optional	`20`	runtime domain; see semantics

Output and exit contract. JSON prime, degree_bound, dimension and coefficients:array of integers.

Semantic boundary. Numerator/denominator lists contain integers, not rational strings. This describes the Mahler-mask functional equation, not automatically the ordinary Taylor coefficients of the rational function with those coefficients.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math generating cartier --numerator 1 --denominator '1,-1' --prime 3 --count 8
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`coefficients`	array[integer]
`degree_bound`	integer
`dimension`	integer
`prime`	integer

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError, RuntimeError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 1028-1049, handler `command_generating_cartier`. Handler SHA-256: `28538bbd947b0ea4f0ec0cef38e6f2fcca7c57fb32b2616e24e33117685acd0b`.

F.5.30 `generating kernel`

Record CLI-F-030. Evaluates a factorial-power kernel modulo a prime power.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi generating kernel [-h] --index INDEX --subindex SUBINDEX
    --prime PRIME --exponent EXPONENT
    --power POWER
```

Argument	Type and requirement	Default	Accepted values
`--index`	int; required	`no default`	runtime domain; see semantics
`--subindex`	int; required	`no default`	runtime domain; see semantics
`--prime`	int; required	`no default`	runtime domain; see semantics
`--exponent`	int; required	`no default`	runtime domain; see semantics
`--power`	int; required	`no default`	runtime domain; see semantics

Output and exit contract. JSON index, subindex, prime, exponent, factorial_power, valuation, unit, residue and survives:boolean.

Semantic boundary. The five required integer arguments are parser-typed only. Prime, exponent, power and index relations receive semantic validation in the kernel compiler.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math generating kernel --index 5 --subindex 2 --prime 3 --exponent 3 --power 2
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 2 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`exponent`	integer
`factorial_power`	integer
`index`	integer
`prime`	integer
`residue`	integer
`subindex`	integer
`survives`	boolean
`unit`	integer
`valuation`	integer

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 1052-1078, handler `command_generating_kernel`. Handler SHA-256: `6281298785cd107525c13c381db67ed0d7dfdf4308a2312c9fe6c849c903cfb3`.

F.5.31 `generating bell`

Record CLI-F-031. Checks one generalized Bell digit-sum reduction.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi generating bell [-h] --index INDEX --prime PRIME --power POWER
```

Argument	Type and requirement	Default	Accepted values
`--index`	int; required	`no default`	runtime domain; see semantics
`--prime`	int; required	`no default`	runtime domain; see semantics
`--power`	int; required	`no default`	runtime domain; see semantics

Output and exit contract. JSON index, prime, factorial_power, digit_sum, high_polynomial, reduced_polynomial and valid:boolean.

Semantic boundary. Power must be at least two and congruent to one modulo prime-1. The returned reduction certificate is required before a success payload is emitted. This is a specified finite modular identity, not an unrestricted convergence claim.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math generating bell --index 8 --prime 3 --power 3
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`digit_sum`	integer
`factorial_power`	integer
`high_polynomial`	array[integer]
`index`	integer
`prime`	integer
`reduced_polynomial`	array[integer]
`valid`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: `(ValidationError, ValueError)`.

Source binding. `src/komorebi_math/cli/main.py`, lines 1081-1105, handler `command_generating_bell`. Handler SHA-256: `40984ce5570a711f7b99458feac393dccb0bccf61df9eda523079caa2b99411f`.

F.5.32 `arithmetic standard-window`

Record CLI-F-032. Computes a residual standard window and requires its finite certificate.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi arithmetic standard-window [-h] --prime PRIME
    --compression COMPRESSION
    [--address ADDRESS] [--count COUNT]
```

Argument	Type and requirement	Default	Accepted values
`--prime`	int; required	`no default`	runtime domain; see semantics
`--compression`	int; required	`no default`	runtime domain; see semantics
`--address`	int; optional	`0`	runtime domain; see semantics
`--count`	int; optional	`20`	runtime domain; see semantics

Output and exit contract. JSON prime, compression, address, period, minimum_period and coefficients.

Semantic boundary. Prime/compression/address compatibility is validated by StandardWindow. –count controls the number of emitted coefficients; zero emits an empty prefix. No file is written.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math arithmetic standard-window --prime 5 --compression 2 --count 8
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 2 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`address`	integer
`coefficients`	array[integer]
`compression`	integer
`minimum_period`	integer
`period`	integer
`prime`	integer

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 422-439, handler `command_standard_window`. Handler SHA-256: `a5265e63fec3036a05eab6c1b52aa29373b4aaa2fbab5b7ed3367be40b951861`.

F.5.33 `arithmetic euler`

Record CLI-F-033. Reconstructs one local Euler value exactly or computes a depth-truncated record.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi arithmetic euler [-h] --prime PRIME --index INDEX
    [--depth DEPTH]
```

Argument	Type and requirement	Default	Accepted values
`--prime`	int; required	`no default`	runtime domain; see semantics
`--index`	int; required	`no default`	runtime domain; see semantics
`--depth`	int; optional	`not supplied`	runtime domain; see semantics

Output and exit contract. Without depth: prime, index, value:string, exact:true. With depth: prime, index, depth, value:string, exact_value, modulus and error:string.

Semantic boundary. Providing –depth switches both the computation and the output schema. The truncated result certificate is required; do not interpret that branch as the exact:true branch.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math arithmetic euler --prime 5 --index 6
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 2 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`exact`	boolean
`index`	integer
`prime`	integer
`value`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 442-469, handler `command_euler_coordinates`. Handler SHA-256: `c3b7ca43c3066d65ad19e524961b586b44c349499c9c0c271db80bacc82836be`.

F.5.34 `deformation count`

Record CLI-F-034. Computes a finite smooth, weighted, nilpotent or normal-crossing chart count.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi deformation count [-h]
    --chart {smooth, weighted, nilpotent, normal-crossing}
    --q Q --depth DEPTH [--dimension DIMENSION]
    [--weights WEIGHTS] [--exponent EXPONENT]
```

Argument	Type and requirement	Default	Accepted values
`--chart`	str; required	`no default`	smooth, weighted, nilpotent, normal-crossing
`--q`	int; required	`no default`	runtime domain; see semantics
`--depth`	int; required	`no default`	runtime domain; see semantics
`--dimension`	int; optional	`1`	runtime domain; see semantics
`--weights`	str; optional	`'1'`	runtime domain; see semantics
`--exponent`	int; optional	`2`	runtime domain; see semantics

Output and exit contract. JSON chart, q, depth and count:integer.

Semantic boundary. –dimension is used only for smooth; –weights only for weighted; –exponent only for nilpotent. q is constructor-validated. Parser acceptance of an integer is not the mathematical domain check.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math deformation count --chart smooth --q 3 --depth 2
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`chart`	string
`count`	integer
`depth`	integer
`q`	integer

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 472-492, handler `command_deformation_count`. Handler SHA-256: `ee39bb86ba97b2b25d8067a48f670c9b9ee76e9ef783d92306f8e029d6093e95`.

F.5.35 `langlands tame-orbit`

Record CLI-F-035. Inspects a finite tame Frobenius orbit and its regularity/self-duality.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi langlands tame-orbit [-h] --q Q --degree DEGREE
    --exponent EXPONENT
```

Argument	Type and requirement	Default	Accepted values
`--q`	int; required	`no default`	runtime domain; see semantics
`--degree`	int; required	`no default`	runtime domain; see semantics
`--exponent`	int; required	`no default`	runtime domain; see semantics

Output and exit contract. JSON q, degree, exponent, orbit, regular, self_dual and regular_orbit_count.

Semantic boundary. The finite orbit certificate is required. Parameters are not a certificate of a general local-global correspondence.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math langlands tame-orbit --q 3 --degree 2 --exponent 1
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`degree`	integer
`exponent`	integer
`orbit`	array[integer]
`q`	integer
`regular`	boolean
`regular_orbit_count`	integer
`self_dual`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 495-511, handler `command_tame_orbit`. Handler SHA-256: `c3b7117ba92f41d9600415139cfd10efc0f95ef3fdea28e8100cabe759bf2ab4`.

F.5.36 `langlands heisenberg`

Record CLI-F-036. Builds and checks one finite Schrodinger Heisenberg model.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi langlands heisenberg [-h] --prime PRIME --rank RANK
```

Argument	Type and requirement	Default	Accepted values
`--prime`	int; required	`no default`	runtime domain; see semantics
`--rank`	int; required	`no default`	runtime domain; see semantics

Output and exit contract. JSON prime, rank, dimension and selector_rank.

Semantic boundary. Trace-support and selector certificates are required. Dimension grows with the parameters; the small reference command is not a large-scale resource promise.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math langlands heisenberg --prime 3 --rank 1
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`dimension`	integer
`prime`	integer
`rank`	integer
`selector_rank`	integer

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 514-528, handler `command_heisenberg`. Handler SHA-256: `2adc69327aa3933f57adb01e41ea0f1b0614ef6920809f773fc5c94f256e40ac`.

F.5.37 `langlands completion`

Record CLI-F-037. Evaluates five flags supplied by the caller as a conditional completion report.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi langlands completion [-h] [--satisfied SATISFIED]
```

Argument	Type and requirement	Default	Accepted values
`--satisfied`	str; optional	`''`	runtime domain; see semantics

Output and exit contract. Certificate JSON with exactness=conditional. Empty/partial gates return 1; all five supplied return 0; unknown gate names return 2 and stderr.

Semantic boundary. The CLI does not prove the supplied gates. Passing –satisfied for all names asserts external assumptions, not a mathematical proof or unconditional automorphy result.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math langlands completion
```

Observed reference result. Exit 1. This is the expected unmet-gate rejection, not completion. 3 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`assumptions_checked`	array (empty in this fixture)
`assumptions_unchecked`	array[string]
`diagnostics`	object
`exactness`	string
`message`	string
`residuals`	object
`theorem_id`	string
`tolerance`	null
`valid`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 531-547, handler `command_completion`. Handler SHA-256: `23f991ded93a18786d71eddcddb4bacb8aa59b1311b8a199dc48fc910fbe8202`.

F.5.38 `export formats`

Record CLI-F-038. Lists supported export format names.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi export formats [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON formats:array of strings.

Semantic boundary. The list has 11 format names. The YAML backend or PDF engine may still be absent. A format name does not mean every source object is exportable to that format.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math export formats
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`formats`	array[string]

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1108-1114, handler `command_export_formats`. Handler SHA-256: `8c04dd63cce128a4f0ace6776a7d3b601688d1f55f8d564bf792caaa18f109f6`.

F.5.39 `export sequence`

Record CLI-F-039. Computes a sequence prefix and exports a mathematical document.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi export sequence [-h] [--terms TERMS] [--modulus MODULUS]
    [--compile] --output OUTPUT [--format FORMAT]
    [--title TITLE] [--author AUTHOR]
    [--date DATE] [--abstract ABSTRACT]
    [--document-class DOCUMENT_CLASS] [--toc]
    [--mathjax]
    [--engine {auto, pdflatex, xelatex, lualatex, latexmk}]
    [--passes PASSES] [--timeout TIMEOUT]
    [--keep-auxiliary] [--no-keep-tex]
    [--no-type-metadata] [--force]
    name
```

Argument	Type and requirement	Default	Accepted values
`name`	str; required	`no default`	runtime domain; see semantics
`--terms`	int; optional	`20`	runtime domain; see semantics
`--modulus`	int; optional	`not supplied`	runtime domain; see semantics
`--compile`	switch; optional	`False`	on/off flag

Also accepts all 16 shared export options from F.3, including required `--output`. The expanded machine-readable record contains every action.

Output and exit contract. JSON acknowledgment path, format, bytes, companion_files and certificate. The destination stores the rendered document/data, not this acknowledgment.

Semantic boundary. There is no –index here. –modulus can use compilation even without –compile. The sequence_ document supplies the title; common –title, –date and –abstract are not propagated to that document by this handler.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math export sequence fibonacci --terms 8 --output sequence.json
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`bytes`	integer
`certificate`	object
`companion_files`	array (empty in this fixture)
`format`	string
`path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1117-1139, handler `command_export_sequence`. Handler SHA-256: `ae14bb99e194db72eb67c0ffe73b8b97d1ebb0da0aac142964fa0b9c018706cf`.

F.5.40 `export standard-window`

Record CLI-F-040. Computes and exports a standard-window report with its certificate.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi export standard-window [-h] --prime PRIME
    --compression COMPRESSION
    [--address ADDRESS] [--count COUNT]
    --output OUTPUT [--format FORMAT]
    [--title TITLE] [--author AUTHOR]
    [--date DATE] [--abstract ABSTRACT]
    [--document-class DOCUMENT_CLASS]
    [--toc] [--mathjax]
    [--engine {auto, pdflatex, xelatex, lualatex, latexmk}]
    [--passes PASSES] [--timeout TIMEOUT]
    [--keep-auxiliary] [--no-keep-tex]
    [--no-type-metadata] [--force]
```

Argument	Type and requirement	Default	Accepted values
`--prime`	int; required	`no default`	runtime domain; see semantics
`--compression`	int; required	`no default`	runtime domain; see semantics
`--address`	int; optional	`0`	runtime domain; see semantics
`--count`	int; optional	`20`	runtime domain; see semantics

Also accepts all 16 shared export options from F.3, including required `--output`. The expanded machine-readable record contains every action.

Output and exit contract. JSON acknowledgment path, format, bytes, companion_files and certificate.

Semantic boundary. The exported document includes the certificate. –format, if supplied, selects the format rather than solely relying on the extension.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math export standard-window --prime 5 --compression 2 --count 8 --output window.json
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 3 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`bytes`	integer
`certificate`	object
`companion_files`	array (empty in this fixture)
`format`	string
`path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1142-1169, handler `command_export_standard_window`. Handler SHA-256: `3d33ed28773e3b27742d8bef9b3b5b6c7b58970569abed2bfe2c905d4bd29590`.

F.5.41 `export euler`

Record CLI-F-041. Exports an exact or depth-truncated local Euler report.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi export euler [-h] --prime PRIME --index INDEX [--depth DEPTH]
    --output OUTPUT [--format FORMAT] [--title TITLE]
    [--author AUTHOR] [--date DATE]
    [--abstract ABSTRACT]
    [--document-class DOCUMENT_CLASS] [--toc]
    [--mathjax]
    [--engine {auto, pdflatex, xelatex, lualatex, latexmk}]
    [--passes PASSES] [--timeout TIMEOUT]
    [--keep-auxiliary] [--no-keep-tex]
    [--no-type-metadata] [--force]
```

Argument	Type and requirement	Default	Accepted values
`--prime`	int; required	`no default`	runtime domain; see semantics
`--index`	int; required	`no default`	runtime domain; see semantics
`--depth`	int; optional	`not supplied`	runtime domain; see semantics

Also accepts all 16 shared export options from F.3, including required `--output`. The expanded machine-readable record contains every action.

Output and exit contract. JSON acknowledgment path, format, bytes, companion_files and certificate.

Semantic boundary. –depth switches the mathematical report payload. An export certificate describes export success; distinguish it from the embedded arithmetic certificate.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math export euler --prime 5 --index 6 --output euler.json
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 4 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`bytes`	integer
`certificate`	object
`companion_files`	array (empty in this fixture)
`format`	string
`path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1172-1208, handler `command_export_euler`. Handler SHA-256: `26c402020d83ace71227723a5d69b6aef249ff07b2c0493c02ec0eaa52c93718`.

F.5.42 `export json`

Record CLI-F-042. Reads UTF-8/UTF-8-BOM JSON from –input and renders it in another supported format.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi export json [-h] --input INPUT --output OUTPUT
    [--format FORMAT] [--title TITLE]
    [--author AUTHOR] [--date DATE]
    [--abstract ABSTRACT]
    [--document-class DOCUMENT_CLASS] [--toc]
    [--mathjax]
    [--engine {auto, pdflatex, xelatex, lualatex, latexmk}]
    [--passes PASSES] [--timeout TIMEOUT]
    [--keep-auxiliary] [--no-keep-tex]
    [--no-type-metadata] [--force]
```

Argument	Type and requirement	Default	Accepted values
`--input`	str; required	`no default`	runtime domain; see semantics

Also accepts all 16 shared export options from F.3, including required `--output`. The expanded machine-readable record contains every action.

Output and exit contract. JSON acknowledgment path, format, bytes, companion_files and certificate.

Semantic boundary. Input parsing, unsupported data shapes and filesystem errors can raise exceptions. –input and –output are not mutually exclusive paths, so use distinct files and avoid –force on the input.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math export json --input input.json --output table.csv
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 19 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`bytes`	integer
`certificate`	object
`companion_files`	array (empty in this fixture)
`format`	string
`path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1211-1220, handler `command_export_json`. Handler SHA-256: `440c38bd62ec7594efbb9c2969b106f4e4da5c8879ab35d01d559f1d82991cf7`.

F.5.43 `export bundle`

Record CLI-F-043. Reads JSON and creates a ZIP containing the requested output formats.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi export bundle [-h] --input INPUT [--base-name BASE_NAME]
    [--formats FORMATS] --output OUTPUT
    [--format FORMAT] [--title TITLE]
    [--author AUTHOR] [--date DATE]
    [--abstract ABSTRACT]
    [--document-class DOCUMENT_CLASS] [--toc]
    [--mathjax]
    [--engine {auto, pdflatex, xelatex, lualatex, latexmk}]
    [--passes PASSES] [--timeout TIMEOUT]
    [--keep-auxiliary] [--no-keep-tex]
    [--no-type-metadata] [--force]
```

Argument	Type and requirement	Default	Accepted values
`--input`	str; required	`no default`	runtime domain; see semantics
`--base-name`	str; optional	`'komorebi_export'`	runtime domain; see semantics
`--formats`	str; optional	`'json,markdown,latex'`	runtime domain; see semantics

Also accepts all 16 shared export options from F.3, including required `--output`. The expanded machine-readable record contains every action.

Output and exit contract. Serialized ExportBundleResult JSON, including destination/member information and certificate; exact fields appear in the observation ledger.

Semantic boundary. –formats is the comma-separated member-format selector. The inherited singular –format is accepted by argparse but ignored by this handler. –base-name governs member names. This is a data-export ZIP, not the library release archive.

File effects and replacement. No destination is written unless the command has a required output or –output is supplied. Existing destination is rejected unless –force. Failure can leave partial artifacts; transactional rollback is not promised.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math export bundle --input input.json --output bundle.zip
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 5 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`__type__`	string
`certificate`	object
`formats`	array[string]
`manifest_path`	string
`members`	array[string]
`path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1223-1240, handler `command_export_bundle`. Handler SHA-256: `3f29595b3c3295d6397f6e84e59d8b43a62b80a1f2c9882226953d923dd6fc8d`.

F.5.44 `latex engines`

Record CLI-F-044. Checks for local LaTeX compiler executables.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi latex engines [-h]
```

No positional arguments or command-specific options beyond help.

Output and exit contract. JSON pdflatex, xelatex, lualatex and latexmk, each boolean.

Semantic boundary. A detected binary is not a successful render, package-availability check or security sandbox.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math latex engines
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 1 associated replay case is retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`latexmk`	boolean
`lualatex`	boolean
`pdflatex`	boolean
`xelatex`	boolean

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1243-1249, handler `command_latex_engines`. Handler SHA-256: `156cceb70723cf26b6ec70dddacbb923fad03603d50f32a66a944868575a5186`.

F.5.45 `latex compile`

Record CLI-F-045. Compiles an existing TeX source into a local PDF and records compiler output.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi latex compile [-h] [--output OUTPUT]
    [--engine {auto, pdflatex, xelatex, lualatex, latexmk}]
    [--passes PASSES] [--timeout TIMEOUT]
    [--keep-auxiliary]
    source
```

Argument	Type and requirement	Default	Accepted values
`source`	str; required	`no default`	runtime domain; see semantics
`--output`	str; optional	`not supplied`	runtime domain; see semantics
`--engine`	str; optional	`'auto'`	auto, pdflatex, xelatex, lualatex, latexmk
`--passes`	int; optional	`2`	runtime domain; see semantics
`--timeout`	float; optional	`120.0`	runtime domain; see semantics
`--keep-auxiliary`	switch; optional	`False`	on/off flag

Output and exit contract. Serialized LatexCompilation JSON: source/pdf/log paths, engine, commands, return_ codes and certificate. 0 means valid compilation, 1 failure; a non-.pdf output is explicitly rejected with 2.

Semantic boundary. Without –output, uses the source path with .pdf suffix. There is no –force and existing PDF/log paths can be overwritten. Compiler timeout is per subprocess, not the total command budget. Shell escape is disabled by default, but arbitrary TeX is not made safe by that flag.

File effects and replacement. Writes PDF, compiler log and auxiliaries. No refusal guard/–force. Existing target artifacts may be replaced; use a fresh directory. Failed compilation may leave files.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math latex compile small.tex --output compiled.pdf --passes 1
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 6 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`__type__`	string
`certificate`	object
`commands`	array[array[string]]
`engine`	string
`log_path`	string
`pdf_path`	string
`return_codes`	array[integer]
`source_path`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 1252-1273, handler `command_latex_compile`. Handler SHA-256: `5a9195661dcae58c3d32090a196ca969e8a24fd25e898848e4f5694a98c45fd1`.

F.5.46 `describe`

Record CLI-F-046. Looks up registered mathematical provenance for a fully qualified object name.

Syntax. Parser-generated usage reflowed for print, with optional groups in square brackets. Exact help text is retained in the inventory.

```
usage: komorebi describe [-h] object
```

Argument	Type and requirement	Default	Accepted values
`object`	str; required	`no default`	runtime domain; see semantics

Output and exit contract. Provenance-record JSON on success. Missing record: stderr text and exit 1.

Semantic boundary. This is a provenance registry lookup, not arbitrary Python evaluation or proof verification.

File effects and replacement. No output-file option. This command does not intentionally overwrite user data; stdout can be redirected by the shell.

Minimum invocation (POSIX and PowerShell). The same one-line command is valid in either shell; run from the scratch fixture directory with a fresh output destination.

```
python -m komorebi_math describe komorebi_math.PacketSystem
```

Observed reference result. Exit 0. The bounded invocation completed successfully. 2 associated replay cases are retained, including shared-suite selections or variants where applicable.

Reference stdout field/type matrix.

Field	Type at this invocation
`assumptions`	array[string]
`identifier`	string
`limitations`	array (empty in this fixture)
`source`	string
`status`	string
`title`	string
`verification_suite`	string

Failure handling. All parser help requests exit 0. Missing/unknown/conflicting arguments and invalid parser choices/types exit 2 with usage on stderr. No global CLI exception normalizer exists: uncaught implementation/-filesystem errors normally terminate the Python process with code 1 and a traceback. Command-specific 0/1/2 behavior is described above. Handler-local caught exception types: none explicitly caught.

Source binding. `src/komorebi_math/cli/main.py`, lines 386-392, handler `command_describe`. Handler SHA-256: `3bdefc2c3242360f900eb71cab98a1d6aed1aaa1ff8a2b1565e5e26f7c2cef09`.

F.6 Recorded replay outcome and boundaries

The documentation bijection covers all 46 leaf commands. All 57 help nodes and all 201 non-help argument records are checked. The installed-wheel reference replay completed **243 cases** with all declared outcome predicates satisfied. That includes intentional nonzero exits for incomplete streams, corrupted chunks, invalid arguments/data, protected output paths and unavailable qualification gates. It does not mean every invoked verification gate passed.

The installed verification dispatch selections produced **50 successful suites and one failed GPU suite**. Four CUDA checks within that failed suite remained negative. Current-platform evidence, final readiness and required-GPU qualification were also negative. A separate validator invoked with `--require-all-gates` refuses to turn these observations into final qualification.

The recorded source suite passed 1,203 tests. The separate parser/ledger suite passed 509 tests. The replay executes the 46 default/minimal commands plus variants, so command, help, suite and test counts are overlapping evidence classes. These observations bind the unchanged mathematical reference package, its tests, and its distributions. The generated manual source, standalone appendix, selector ledger, inventory and replay validation scripts are included for reproducibility.

The replay uses a valid positive Bell power and the qualification report's actual field structure. It retains the expected GPU rejection and the rejection of dictionary input for NPY. The initial failed fixture records are preserved separately. These distinctions belong to the fixture contract and do not indicate a change to the package implementation.

Appendix F is complete as a version-bound CLI reference with finite Linux execution evidence. Native PowerShell, Windows, other Python versions, CUDA, strict MkDocs and fully dependency-isolated installation remain unqualified. Appendix G describes portable schemas and migrations. The subsequent appendices retain the separate supporting reference layers.

Appendix G. Portable schemas and migrations

Start with the file you need to recover. This appendix helps you choose a storage representation, understand its fields, and diagnose a failed load. For a first ordinary save-and-load example, go directly to G.9, then return to G.1 to understand the representation it uses.

Your task	Read first	Keep in view
Save one supported object and load it later	G.1, G.4 and G.9	The portable envelope and the decoded object are different layers.
Inspect a particular saved type	Its G.7 codec record	Match the tag and codec version before interpreting the fields.
Read an older packet-jet snapshot	G.5	Preserve the original and let the registered migration reconstruct the current object.
Resume or inspect a chunked snapshot	G.8	Check the stream's completion state as well as its chunk integrity.

Read a codec record from the outside inward. First identify the envelope, then the tagged payload, then the decoded fields, and finally the reconstructed Python object. The field table describes the decoded data supplied to reconstruction. For example, a matching payload digest shows agreement with the stored checksum; the codec's own paragraph explains which structural or mathematical checks follow. Keeping those steps separate makes a loading error much easier to locate.

G.0 Scope, status and how to use this reference

This appendix describes the executable persistence layer shipped in Komorebi Math 1.0.0b4, Repair R2, wheel build tag 2. It covers **all 51 frozen mathematical codecs, their 214 encoder fields, the single committed adjacent migration, canonical payloads, digest boundaries and resource limits**. Nine built-in scalar/container tags and 26 finite primitive fixtures are documented separately from the 51 mathematical registry entries. The stream directory and codec compatibility contract are separate schemas, not additional entries in that registry.

The observations in this reference describe the behavior of the stated source baseline. This reference does not silently tighten a decoder, change a schema version, certify arbitrary stored claims or qualify another platform. The fixture collection is deliberately small and deterministic. Its completeness is a coverage statement about the frozen registry, not exhaustive testing of every possible input value.

Each G-C record gives the codec tag and version, represented Python type, the complete decoded encoder-field table, a concrete canonical JSON fixture, payload digest, migration path, decoder behavior and source binding. **Field types in the table describe the displayed fixture.** They do not assert a formal JSON Schema, a universal type checker, or every possible union accepted by a decoder. The encoded data are recursively tagged, so a decoded field table is not a literal untagged JSON record.

The machine-readable reference retains full encoder, decoder and class-source locations and SHA-256 digests. Full pretty and compact canonical UTF-8 envelopes live in `manual/current/block39-fixtures`. The source-bound fixture generator, stream replay, mutation tests and archive verifier are included under `tools/block39` and at the delivery root. Reproduction should be performed in a working copy, not by changing files in an attested extraction.

G.1 Choose the representation before writing a file

Representation	Intended use	Reconstruction and integrity boundary
`to_serializable` / `from_serializable`	Broad presentation and export	Built-in markers can recover selected scalars/arrays. Unknown `__type__` records remain dictionaries. This is not the portable envelope.
`to_portable_data` / `from_portable_data`	An in-memory encoded payload tree	Uses explicit tags and versions. There is no envelope digest at this layer.
`dumps_portable` / `loads_portable`	One complete UTF-8 JSON document	Requires the exact portable envelope and verifies its payload digest before decoding.
`save_portable` / `load_portable`	One disk file	Adds file I/O and guarded replacement. It does not add authentication or a global size cap.
Packet-jet stream directory	Chunked fixed finite jet data	Uses distinct manifest and chunk envelopes, progress records, independent digests and explicit incomplete-state semantics.
Portable codec compatibility contract	Frozen release inventory	Compares tag/type/version identities and migration edges. It is not the serialized mathematical object itself.

Converting an ordinary export report into a portable record requires deliberate reconstruction of a supported object and then portable encoding. Renaming `__type__` to `__komorebi_type__`, inserting a version, or copying a CLI report into an envelope is not a supported migration. Likewise, a `.json` extension does not identify which schema it contains.

G.2 The exact single-document envelope

A newly emitted envelope has exactly five keys: `schema`, `schema_version`, `producer_version`, `payload` and `payload_sha256`. The schema string is `komorebi-math.portable`, and its current schema version is 1. The producer is the package version string, not the wheel build tag. The current implementation requires the producer field to be present but does not validate its type or value.

Only the **payload** participates in `payload_sha256`. Producer metadata is not bound by that digest. Changing the payload without changing its digest is rejected. Changing both together can produce another accepted document. This is corruption detection, not authentication, authorization, confidentiality or an independent mathematical certificate.

The canonical byte calculation is the implementation's exact JSON serialization:

```
canonical_payload = json.dumps(
    payload,
    sort_keys=True,
    separators=(",", ":"),
    ensure_ascii=False,
    allow_nan=False,
).encode("utf-8")
payload_sha256 = hashlib.sha256(canonical_payload).hexdigest()
```

This is the package's canonicalization rule, not a claim of conformity to a separate cross-language canonical-JSON standard. Key sorting, retained Unicode, finite numbers and separators matter. Whitespace in a loaded envelope need not match the writer. Duplicate JSON object keys are rejected by the parser hook, as are nonstandard `NaN` and infinity constants. The parser validates UTF-8 byte input and requires a JSON-object root.

A tagged value has exactly `__komorebi_type__`, `__version__` and `data`. The tag resolves only through known built-ins or the active trusted registry. No serialized import path selects an arbitrary Python class. Unknown tags and

future codec versions are rejected. Registered decoder and migrator callbacks are trusted application code, not code sandboxed by this format.

Observed permissive version boundary. The outer schema version is compared by equality with 1, so JSON `true` and `1.0` are accepted there. The codec version validator rejects booleans but accepts an integral float such as `1.0`. The canonical writer emits integers. Applications requiring strict untrusted-input typing must apply a stricter policy before relying on these fields.

G.3 Scalar, container and ndarray forms

Native null, booleans, integers, strings and finite floats pass through without a type tag. A list is recursively encoded as a JSON array. NumPy scalar inputs normalize through `.item()` rather than retaining a NumPy scalar class. Generic supported sequences can normalize to tuples. The format is not a general Python object graph serializer: aliases, shared references, arbitrary classes, open files, generators and callback code are not automatically preserved.

Built-in tag	Version	Literal `data` representation
`python.fraction`	1	Object containing `numerator` and `denominator`. The writer emits integer values.
`python.complex`	1	Object containing finite `real` and `imag` values.
`python.path`	1	Path spelling as a string. Loading creates a Path, not a file read.
`python.bytes`	1	Validated base64 string.
`python.tuple`	1	Array of recursively encoded members.
`python.set`	1	Array sorted by canonical encoded member spelling.
`python.frozenset`	1	The same array rule, restoring an immutable set.
`python.mapping`	1	Array of two-element arrays, sorted by the canonical encoded key.
`numpy.ndarray`	1	Exact keys `dtype`, `shape`, `data`; flat recursively encoded values and an integer shape array.

Mappings can preserve heterogeneous hashable keys, including fractions and tuples. The loader rejects duplicate decoded keys, including a collision between integer 1 and boolean true. Unhashable mapping keys and set items are rejected. Duplicate set entries, by contrast, are coalesced by set construction rather than rejected.

An untagged JSON object without `__komorebi_type__` is accepted by the low-level decoder as a mapping. Re-encoding it uses the tagged mapping form. Acceptance therefore does not imply that the input was an encoder-canonical payload.

For ndarrays the writer flattens values with `reshape(-1).tolist()`. The decoder restores a NumPy dtype, checks nonnegative dimensions and the product of shape against the flat length, then reconstructs the array. A scalar shape needs one flat entry, and a shape with a zero dimension needs none. Object-array elements are recursively encoded, not pickled. This still does not preserve memory strides, views, aliasing or device placement.

Array scope. Finite integer, floating, complex, boolean, Unicode, empty, scalar and exact-fraction object arrays have explicit fixtures. Not every NumPy dtype is a supported round-trip. A structured dtype is an observed counterexample: encoding succeeds but reconstruction rejects its dtype spelling. Do not generalize a successful numeric-array test to all NumPy dtypes.

Coercion scope. Fraction numerator/denominator and ndarray dimensions are converted with `int`. The decoder can accept fractional numeric inputs by truncating them. Examples include numerator 1.9 becoming 1 and dimension 2.9 becoming 2. These are tested acceptance boundaries, not endorsed canonical inputs. Canonical fixtures use integers in those fields.

G.4 Current portable API, file effects and errors

API	Defaults and return	Important boundary
`to_portable_data(value, *, max_depth=128)`	Encoded payload tree	No envelope or integrity check is added.
`from_portable_data(value, *, max_depth=128)`	Reconstructed value	Input must use supported nodes and tags; some noncanonical coercible data are accepted.
`portable_digest(value, *, max_depth=128)`	Lowercase payload SHA-256	Hashes the encoded object, not an arbitrary caller-supplied envelope.
`dumps_portable(value, *, indent=2, max_depth=128)`	JSON text ending with newline	Writer emits finite JSON and all five envelope keys.
`loads_portable(text, *, max_depth=128)`	Reconstructed value	Accepts text or UTF-8 bytes, checks envelope and payload digest, then decodes.
`save_portable(value, path, *, overwrite=False, indent=2, max_depth=128)`	Destination Path	Creates parents, writes a temporary file, flushes and fsyncs it, then replaces the destination.
`load_portable(path, *, max_depth=128)`	Reconstructed value	Reads the complete file before decoding. A missing/unreadable file raises ValidationError.
`register_portable_codec(type_, *, tag, version, encoder, decoder, replace=False)`	None	Type, callable, tag and version validation; deliberate replacement changes the active registry.
`register_portable_migration(*, tag, from_version, to_version, migrator, replace=False)`	None	An adjacent increment only. The parameter is `migrator`, not `migrate`.
`portable_codecs()` / `portable_migrations()`	Sorted tuples	Trigger built-in registration; extension-owned entries can exist in the active registry.

`save_portable` refuses an already existing destination unless overwrite is explicit. The test injects a replacement failure and verifies the original file and temporary-file cleanup. These are finite local checks of the implemented failure path. They are not a claim of crash durability of every filesystem, protection against concurrent writers, or a cross-platform file-locking guarantee. The existence check and the eventual replacement are separate operations.

Most decode failures are ValidationError. Registered decoder exceptions other than ValidationError are wrapped with the codec tag. Encoder exceptions are not uniformly wrapped: an opaque callback basis raises ValueError, and an operating-system write failure can propagate OSError. Applications should not assume every failure has one exception type.

G.5 Migration, compatibility and trust

A migration acts on **already recursively decoded codec data**, not on raw JSON text and not on the whole envelope. The loader validates the old payload digest before applying the migration. The reconstructed object re-encodes at the current codec version and generally has a new payload digest. Keep the original old envelope intact when retaining provenance.

Only one migration ships in the frozen baseline:

The `nonlinear.packet_jet_snapshot` codec migrates **version 1 to version 2**. It renames decoded `provider_name` to `provider`, introduces `coefficient_ordering` with value `"lexicographic"`, and carries the other snapshot fields unchanged.

Version 1 cannot be interpreted as version 2 by merely changing the version number. The legacy fixture is a genuine v1 field layout with a recomputed v1 payload digest. Loading it traverses the registered migration and reproduces the current finite snapshot. A future v3 payload is rejected.

For an extension, each edge must be `n -> n+1`. A missing intermediate edge, a future version, an invalid version, or a failing migrator raises an error. Duplicate edges require an explicit `replace=True`. Tests exercise a two-step custom chain, a missing link, duplicate registration, a nonadjacent edge and a failing callback. Registration requires a callable but does **not** prove that the callback is deterministic, pure, terminating or mathematically equivalent. Those remain the extension author's obligations.

```
from komorebi_math.export import register_portable_migration

register_portable_migration(
    tag="my_project.record",
    from_version=1,
    to_version=2,
    migrator=lambda data: {**data, "schema_name": "record-v2"},
)
```

This registration example alone does not install the extension's codec. The corresponding trusted type, encoder and decoder must be registered before such records can be reconstructed. Built-in registration is lazy and uses deliberate replacement for its own entries. Call `portable_codecs()` before introducing controlled extension registrations, and do not use replacement as an ordinary way to override package contracts.

The committed compatibility contract uses schema `komorebi-math.portable-codec-contract`, version 1, with exact top-level keys `schema`, `schema_version`, `package_version`, `entries`. Each entry has `tag`, `version`, `implementation_type`. Entries are deterministically ordered and tags are unique. The frozen package-owned inventory is 51 entries. The comparator rejects removed tags, changed represented types, decreased versions and increases without every adjacent edge. Additions are permitted. The comparator checks registry structure, not migrator semantics or every possible object representation.

The ordinary contract-file loader uses its own JSON path, not the portable envelope. The contract format does not gain payload authentication merely because it names codecs. Custom extension codecs are excluded from the package-owned snapshot unless their represented Python type claims a `komorebi_math.` module prefix. Type ownership here is a naming convention, not an authentication system.

G.6 Resource policy and integrity limits

`max_depth=128` is the generic portable traversal limit, starting at depth zero. It is not a file-byte, array-element, CPU-time or memory cap. `load_portable` reads the whole file, `loads_portable` parses JSON before the portable walk, and digest canonicalization materializes JSON text before reconstruction. Large valid-looking inputs can therefore consume resources before the traversal bound is reached. Extremely deep inputs may encounter Python's own parser or recursion limits first.

Component	Enforced or represented limit	What it does not automatically limit
Generic portable walk	Configured recursive depth	File bytes, integer digit count, overall node count, allocation size, decoder runtime
ndarray reconstruction	Nonnegative converted shape and matching flat length	A global maximum number of elements or total bytes
GeneratingBudget	Eight declared per-operation limits	Global JSON loading or every decoder merely because the budget is nested in a record
CoordinateBudget	Four declared per-operation limits	Generic persistence memory or all coordinate operations without explicit budget use
Finite frozen function	Captured degree	The original callback or any extension beyond that finite prefix
Stream selection/load	Explicit coefficient selection/materialization cap	The size of an arbitrary chunk file before it is parsed
Direct jet capture	Explicit evaluation budget per invocation	The exponential total basis count of the underlying finite jet

Component	Enforced or represented limit	What it does not automatically limit

Default GeneratingBudget fields are maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864 and maximum_recursion_depth=1000. CoordinateBudget defaults are maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096 and maximum_exact_entries=1000000. These values are also source-bound in their record fixtures.

A record with `maximum_serialized_bytes=1` still serializes and loads through the generic API. That test demonstrates the distinction between a stored policy and an enforced universal cap. For untrusted data, callers should bound input bytes, nesting, element counts and trusted callback execution before treating this format as a service boundary. This appendix does not certify the current decoder as a strict hostile-input validator.

A certificate's stored `valid` field is data. Many result codecs lack the original mathematical inputs needed to re-run the computation. Some specialized decoders do perform finite checks, such as Kummer count recomputation, analysis/synthesis certification and mask-plan compilation. Their stronger checks are identified in the corresponding records. Do not promote every successfully decoded object to the same evidentiary status.

G.7 Complete mathematical codec records

The 51 records below match the committed registry one for one. Encoder-field tables are complete for the pinned version. Every field was removed individually in a malformed fixture and rejected. Extra decoded data fields were rejected by 39 codecs but ignored by 12 core/nonlinear/deformation codecs. The outer tagged wrapper rejects extra keys for all 51. The three facts refer to different layers and must not be conflated.

G.7.1 `arithmetic.polyphase_coordinates`

Record G-C01. Codec version 1. Represented type: `komorebi_math.arithmetic.polyphase.ArithmeticPolyphase`.

Exact arithmetic lanes use a positive modulus, tuple channels and a finite sequence length. Reconstructing the fixture recovers its rational sequence. The record stores lanes, not an infinite sequence rule. Rational arithmetic and finite shape consistency are distinct from any analytic continuation claim.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`channels`	`tuple[tuple; length=3]`
`length`	`int`
`modulus`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/arithmetic.polyphase_coordinates.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `d7ced187ff65537988308ba70e360db24e37b314d590ad7494b7a8248765163b`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/refinement/portable.py`, lines 137-141. Decoder: `src/komorebi_math/refinement/portable.py`, lines 63-70. Represented class: `src/komorebi_math/arithmetic/polyphase.py`, lines 14-57. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.2 `coordinates.affine_transform`

Record G-C02. Codec version 1. Represented type: `komorebi_math.coordinates.affine.AffineCoordinateTransform`.

The decoder converts the matrix and offset through exact rational conversion, then constructs an affine transform. Source, target, theorem and description are labels carried with the data. Invertibility or a separately asserted theorem is not established merely by serializing those labels.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`description`	`str`
`matrix`	`tuple[tuple; length=2]`
`offset`	`tuple[Fraction; length=2]`
`source`	`str`
`target`	`str`
`theorem`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.affine_transform.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `8e4e1529aa5acbd40f6de85eb969431867e89642bd02ef0c2bd7f5c7448a61a0`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 464-471. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 176-186. Represented class: `src/komorebi_math/coordinates/affine.py`, lines 27-148. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.3 `coordinates.analysis_synthesis`

Record G-C03. Codec version 1. Represented type: `komorebi_math.coordinates.analysis_synthesis.AnalysisSynthesisSystem`.

Analysis and synthesis remain NumPy arrays with their declared dtypes. The decoder reconstructs the system and requires its certificate. This finite numerical check uses the stored tolerance. It is not an exact symbolic proof or independent validation that a caller-selected tolerance is appropriate.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`analysis`	`ndarray[float64; shape=(2, 2)]`
`coordinates`	`str`
`source`	`str`
`synthesis`	`ndarray[float64; shape=(2, 2)]`
`theorem`	`str`
`tolerance`	`float`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.analysis_synthesis.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `b777f8217c51a107c59748c1e6bec1cd736168b80c2abc01f317f2aa904ee557`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 518-525. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 224-236. Represented class: `src/komorebi_math/coordinates/analysis_synthesis.py`, lines 127-381. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.4 `coordinates.atlas`

Record G-C04. Codec version 1. Represented type: `komorebi_math.coordinates.basis.CoordinateAtlas`.

Systems and transforms are nested portable records. The decoder requires CoordinateSystem nodes and CoordinateTransform edges, registers them in the reconstructed atlas, and uses include_inverse=False while replaying stored edges. Inverses present in the saved graph remain explicit, rather than being silently regenerated.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`name`	`str`
`systems`	`tuple[CoordinateSystem; length=2]`
`transforms`	`tuple[CoordinateTransform; length=2]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.atlas.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `a417ec64d549f062a4c06b84e3f73f10fcfcbcf6ad9a07afaba5ecf35f865acf`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 439-443. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 150-162. Represented class: `src/komorebi_math/coordinates/basis.py`, lines 260-418. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.5 `coordinates.barycentric_system`

Record G-C05. Codec version 1. Represented type: `komorebi_math.coordinates.affine.BarycentricCoordinateSystem`.

Vertices are converted row by row to exact vectors and passed to BarycentricCoordinateSystem. The name and finite vertices are the complete encoder fields. This record does not capture a global geometric atlas or a triangulation algorithm.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`name`	`str`
`vertices`	`tuple[tuple; length=3]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.barycentric_system.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `85b32c5e4fecc0d5f15a125d5a7d6c6dfb4029f3e40889e506fbfe6779cc40d9`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 479-482. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 189-195. Represented class: `src/komorebi_math/coordinates/affine.py`, lines 151-231. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.6 `coordinates.bezout_defect_identity`

Record G-C06. Codec version 1. Represented type: `komorebi_math.coordinates.operators.BezoutDefectIdentity`.

All five polynomial vectors pass through exact conversion. The valid field is converted with bool. When that converted flag is true, the decoder requires the reconstructed result certificate. A false flag is retained without that require call. This is narrower than re-proving every possible interpretation of the stored multipliers.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`expected`	`tuple[Fraction; length=1]`
`gcd`	`tuple[Fraction; length=1]`
`left_multiplier`	`tuple[Fraction; length=1]`
`reconstructed`	`tuple[Fraction; length=1]`
`right_multiplier`	`tuple[Fraction; length=1]`
`valid`	`bool`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.bezout_defect_identity.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `175235855ca6d89d4ea5fa15bc7ee480e989801d790a506788fd9ad734b018d9`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 410-417. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 115-135. Represented class: `src/komorebi_math/coordinates/operators.py`, lines 76-97. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.7 `coordinates.budget`

Record G-C07. Codec version 1. Represented type: `komorebi_math.coordinates.budget.CoordinateBudget`.

The four limits are converted to integers and stored in CoordinateBudget. They describe a resource policy for coordinate operations that explicitly accept that policy. A serialized budget is not a process-wide limit on JSON parsing, decoder memory or other objects in the same document.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`maximum_exact_entries`	`int`
`maximum_horizon`	`int`
`maximum_matrix_dimension`	`int`
`maximum_polynomial_degree`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.budget.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `31472fd64d7de117fe8f92b2e3b7da7d5b08c3c745b3d72f2bdd1646222996e8`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 318-323. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 37-45. Represented class: `src/komorebi_math/coordinates/budget.py`, lines 10-65. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.8 `coordinates.finite_basis`

Record G-C08. Codec version 1. Represented type: `komorebi_math.coordinates.basis.FiniteBasis`.

Vectors pass through exact rational conversion and labels through string conversion. The declared basis includes its name, labels and description. The constructor remains the authority on finite consistency; persistence does not extend the basis beyond the stored vectors.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`description`	`str`
`labels`	`tuple[str; length=2]`
`name`	`str`
`vectors`	`tuple[tuple; length=2]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.finite_basis.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `6594540e52c27746385bd0cdc815eeef5ccfc9ec0ea1474341c5f8d1299646e4`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 451-456. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 165-173. Represented class: `src/komorebi_math/coordinates/basis.py`, lines 54-217. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.9 `coordinates.finite_field_transform`

Record G-C09. Codec version 1. Represented type: `komorebi_math.coordinates.modular.FiniteFieldCoordinateTransform`.

Matrix entries and prime are converted with int before construction. The constructor controls the finite-field transform contract. The loader does not preserve the original lexical representation of numeric inputs, and coercible inputs should not be confused with strictly typed JSON integers.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`description`	`str`
`matrix`	`tuple[tuple; length=2]`
`prime`	`int`
`source`	`str`
`target`	`str`
`theorem`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.finite_field_transform.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `cbe38e903bff429a00f3e8251da0a748d592210083470422e3ced5342e969afe`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 503-510. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 209-219. Represented class: `src/komorebi_math/coordinates/modular.py`, lines 85-210. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.10 `coordinates.formal_change`

Record G-C10. Codec version 1. Represented type: `komorebi_math.coordinates.formal.FormalCoordinateChange`.

The finite coefficient vector is converted to exact rationals. Source and target coordinate names are retained. Only the supplied formal prefix is stored, not an analytic map defined on a global domain or a proof of convergence.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`coefficients`	`tuple[Fraction; length=3]`
`name`	`str`
`source`	`str`
`target`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.formal_change.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `a81d12bb6b719f1c8d2ab4ced797a2c6`

`c1df7cd7ca0180fc265181131f77d76b`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 490-495. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 198-206. Represented class: `src/komorebi_math/coordinates/formal.py`, lines 54-241. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.11 `coordinates.intertwiner_space`

Record G-C11. Codec version 1. Represented type: `komorebi_math.coordinates.realization.IntertwinerSpace`.

The decoder converts dimensions to integers and each stored basis matrix to exact form. It reconstructs a basis record, but the original pair of source and target operators is not among its fields. Therefore decoding alone cannot independently re-solve the original intertwining problem.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`basis`	`tuple[tuple; length=2]`
`source_dimension`	`int`
`target_dimension`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.intertwiner_space.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `82e065b2557027228b80e0ba715786a055dae32527f15af0afc05812dbd7629b`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 387-391. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 100-107. Represented class: `src/komorebi_math/coordinates/realization.py`, lines 124-166. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.12 `coordinates.linear_realization`

Record G-C12. Codec version 1. Represented type: `komorebi_math.coordinates.realization.LinearRealization`.

Transition, initial and output are exact matrices/vectors after decoding. They define the stored finite state realization with its name. Equivalent realizations are not automatically identified or minimized by the persistence layer.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`initial`	`tuple[Fraction; length=2]`
`name`	`str`
`output`	`tuple[Fraction; length=2]`
`transition`	`tuple[tuple; length=2]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.linear_realization.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `01ae83c639d05c400f1ed9c137f9d64dce80a351c2be604a15202be8c029fdce`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 358-363. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 73-81. Represented class: `src/komorebi_math/coordinates/realization.py`, lines 37-86. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.13 `coordinates.modal_system`

Record G-C13. Codec version 1. Represented type: `komorebi_math.coordinates.numeric.ModalCoordinateSystem`.

The decoder requires both nested transforms to decode as NumericCoordinateTransform, and converts diagonal_residual to float. Eigenvalues and the two transforms are restored. The original operator is not encoded here, so its eigenproblem is not independently recomputed during decoding.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`analysis`	`komorebi_math.coordinates.numeric.NumericCoordinateTransform`
`diagonal_residual`	`float`
`eigenvalues`	`ndarray[float64; shape=(2,)]`
`synthesis`	`komorebi_math.coordinates.numeric.NumericCoordinateTransform`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.modal_system.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `691b0ba59605bae84cd4a23b00d37df774d146d301f92b39c428ce9ed89aeef1`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 548-553. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 251-263. Represented class: `src/komorebi_math/coordinates/numeric.py`, lines 287-312. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.14 `coordinates.numeric_transform`

Record G-C14. Codec version 1. Represented type: `komorebi_math.coordinates.numeric.NumericCoordinateTransform`.

The matrix keeps its ndarray representation, and tolerance is converted to float. Source, target, theorem and description are descriptive fields. The numerical contract must still be interpreted at the declared tolerance and dtype.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
description	str
matrix	ndarray[complex128; shape=(3, 3)]
source	str
target	str
theorem	str
tolerance	float

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.numeric_transform.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `2ba0fb2d2ba3c6eeb44247c6e1618e03ff21fc9a28afbc87817f352aeee231ab`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 533-540. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 238-248. Represented class: `src/komorebi_math/coordinates/numeric.py`, lines 26-164. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.15 `coordinates.polynomial_operator`

Record G-C15. Codec version 1. Represented type: `komorebi_math.coordinates.calculus.PolynomialCoordinateOperator`.

The finite matrix, source/target degrees, family labels, name and theorem label are stored. Exact conversion reconstructs the matrix. Loading this record does not verify an infinite polynomial-family identity beyond the represented finite operator.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
matrix	tuple[tuple; length=3]
name	str
source_degree	int
source_family	str
target_degree	int
target_family	str
theorem	str

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.polynomial_operator.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `b7a355fa665d9ddbdbb85183d05b77951b533d3049cd52e0941f49c997ff3c68`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 588-596. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 289-308. Represented class: `src/komorebi_math/coordinates/calculus.py`, lines 32-102. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.16 `coordinates.recurrence_model`

Record G-C16. Codec version 1. Represented type: `komorebi_math.coordinates.families.RecurrenceModel`.

The coefficients and initial values are converted to exact vectors. The decoder uses the four-argument current constructor, including description. The recorded baseline includes the constructor correction, so the earlier wheel defect is absent from this implementation.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`coefficients`	`tuple[Fraction; length=2]`
`description`	`str`
`initial_values`	`tuple[Fraction; length=2]`
`name`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.recurrence_model.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `92e8e314ebcc20d24a6f81623057fe63c8e7871d06b7f37c9d9679996fe3e85c`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 561-566. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 266-274. Represented class: `src/komorebi_math/coordinates/families.py`, lines 22-136. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.17 `coordinates.recurrence_record`

Record G-C17. Codec version 1. Represented type: `komorebi_math.coordinates.recurrence.RecurrenceCoordinateRecord`.

The decoder reconstructs exact recurrence coefficients, initial values and defects, then requires the record certificate. The finite reconstruction contract is checked. No statement about arbitrary later terms is inferred from a finite defect list.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`coefficients`	`tuple[Fraction; length=2]`
`defects`	`tuple[Fraction; length=6]`
`initial`	`tuple[Fraction; length=2]`
`name`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.recurrence_record.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `85b1158e9f3817e02d9a3a53cb44b697280a7a4f4053d9d0dfb85409df4c9256`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 345-350. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 60-70. Represented class: `src/komorebi_math/coordinates/recurrence.py`, lines 127-208. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.18 `coordinates.shift_polynomial`

Record G-C18. Codec version 1. Represented type: `komorebi_math.coordinates.operators.ShiftPolynomial`.

Coefficients are converted to an exact vector and the ShiftPolynomial constructor establishes its normalized representation. The record includes the optional name. A noncanonical integer input can therefore re-encode differently after exact normalization.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`coefficients`	`tuple[Fraction; length=3]`
`name`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.shift_polynomial.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `d99bd2d700e30c355061cdc09b38bc1d6baa722631c6c4d23c2c3b6f33fc78a2`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 399-402. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 110-112. Represented class: `src/komorebi_math/coordinates/operators.py`, lines 45-73. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.19 `coordinates.state_recovery`

Record G-C19. Codec version 1. Represented type: `komorebi_math.coordinates.realization.StateRecovery`.

The decoder applies bool to exact and unique, int to rank and horizon, and exact vector conversion to state, predicted and residual. The record does not include the original system and observations needed to independently redo the recovery. Stored flags are not fresh mathematical evidence.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`exact`	`bool`
`horizon`	`int`
`predicted`	`tuple[Fraction; length=2]`
`rank`	`int`
`residual`	`tuple[Fraction; length=2]`

Field	Form in the finite fixture
`state`	`tuple[Fraction; length=2]`
`unique`	`bool`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.state_recovery.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `3b11526f93fdb34c57d86f73b0adaff3e57212e4c5b45d9c59f7d35b51a9db2b`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 371-379. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 84-97. Represented class: `src/komorebi_math/coordinates/realization.py`, lines 89-121. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.20 `coordinates.state_space_model`

Record G-C20. Codec version 1. Represented type: `komorebi_math.coordinates.state_space.StateSpaceModel`.

Transition, input, output and feedthrough matrices use exact conversion. The record describes a finite state-space model, not its execution history. File reconstruction is separate from controllability, observability or stability analysis.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`feedthrough`	`tuple[tuple; length=1]`
`input_matrix`	`tuple[tuple; length=2]`
`name`	`str`
`output_matrix`	`tuple[tuple; length=1]`
`transition`	`tuple[tuple; length=2]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.state_space_model.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `6e55b2b3961ef6f9db7476f6ba25554b4ef1521ca04903b68bddedcf46f7b6ca`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 574-580. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 277-286. Represented class: `src/komorebi_math/coordinates/state_space.py`, lines 31-131. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.21 `coordinates.system`

Record G-C21. Codec version 1. Represented type: `komorebi_math.coordinates.basis.CoordinateSystem`.

Name, kind and description pass through string conversion, while dimension passes through int. This is a coordinate-system identity and dimension record. No actual basis matrix is included in this tag.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`description`	`str`
`dimension`	`int`
`kind`	`str`
`name`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.system.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `c82e71385cafdc6288a8153da292341d1af7fa63ed92893b5ee29f6c68a1669a`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 426-431. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 138-146. Represented class: `src/komorebi_math/coordinates/basis.py`, lines 34-51. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.22 `coordinates.transform`

Record G-C22. Codec version 1. Represented type: `komorebi_math.coordinates.transform.CoordinateTransform`.

The five fields reconstruct an exact CoordinateTransform. Matrix values use as_matrix and labels use str. The theorem string is carried metadata rather than a pointer to an executable proof checker.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`description`	`str`
`matrix`	`tuple[tuple; length=2]`
`source`	`str`
`target`	`str`
`theorem`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/coordinates.transform.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `20bf225a216c6ccbf8f71f3a1e5db64cf3cf621b8ac1dd47d41862f20dd364c3`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/coordinates/portable.py`, lines 331-337. Decoder: `src/komorebi_math/coordinates/portable.py`, lines 48-57. Represented class: `src/komorebi_math/coordinates/transform.py`, lines 25-148. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.23 `core.certificate`

Record G-C23. Codec version 1. Represented type: `komorebi_math.certificates.Certificate`.

The loader copies a certificate record, converts valid with bool, and converts residuals and tolerance to floats. It does not re-run the underlying theorem or require the certificate. A stored false certificate round-trips as false. A malformed nonempty string such as "false" converts to true; the boundary test documents this permissive behavior rather than treating it as safe input validation.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`assumptions_checked`	`tuple[empty; length=0]`
`assumptions_unchecked`	`tuple[str; length=1]`
`diagnostics`	`mapping[0 entries]`
`exactness`	`str`
`message`	`str`
`residuals`	`mapping[1 entries]`
`theorem_id`	`str`
`tolerance`	`null`
`valid`	`bool`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/core.certificate.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `ff8eb4772ed098b67bc2fc7d3e85d19a89382f8610fce3adc5a596b8fb7ffb19`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 205-216. Decoder: `src/komorebi_math/export/persistence.py`, lines 219-230. Represented class: `src/komorebi_math/certificates.py`, lines 27-54. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.24 `deformation.lift_branch`

Record G-C24. Codec version 1. Represented type: `komorebi_math.deformation.forests.LiftBranch`.

Only the finite sequence of nodes is encoded. The decoder wraps it in LiftBranch. Extra data fields are ignored by this codec, and persistence does not construct an infinite lift or supply an omitted convergence argument.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`nodes`	`tuple[tuple; length=2]`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/deformation.lift_branch.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `108f4c92d4aff3172b2c0be15721440822d90e1407e8b9ac6d1e39841f23a19a`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 373-373. Decoder: `src/komorebi_math/export/persistence.py`, lines 374-374. Represented class: `src/komorebi_math/deformation/forests.py`, lines 16-26. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.25 `generating.basis_descriptor`

Record G-C25. Codec version 1. Represented type: `komorebi_math.generating.basis.BasisDescriptor`.

The decoder enforces exactly name, kind and parameters, requires a mapping of parameters, and calls BasisDescriptor.create. The descriptor names a controlled declarative basis form. Arbitrary serialized callback code is not supported.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`kind`	`str`
`name`	`str`
`parameters`	`mapping[0 entries]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.basis_descriptor.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `93ae0a2a81c50e563cb78fdd6f4af259ea6bae6c4aec3676a6d58c02d8e5601f`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 346-350. Decoder: `src/komorebi_math/generating/portable.py`, lines 130-136. Represented class: `src/komorebi_math/generating/basis.py`, lines 22-62. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.26 `generating.budget`

Record G-C26. Codec version 1. Represented type: `komorebi_math.generating.budget.GeneratingBudget`.

All eight fields pass through int into GeneratingBudget. These stored limits become effective only where an operation explicitly checks them. In particular, maximum_serialized_bytes does not impose a global input-size limit on dumps_portable or loads_portable.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`maximum_coefficient_bits`	`int`
`maximum_degree`	`int`
`maximum_local_combinations`	`int`
`maximum_matrix_dimension`	`int`

Field	Form in the finite fixture
`maximum_modulus`	`int`
`maximum_reachable_states`	`int`
`maximum_recursion_depth`	`int`
`maximum_serialized_bytes`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.budget.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `61397a505f1c39f55f5e49d4bb3223aef3e867968d84320e56b747da8980c093`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 366-375. Decoder: `src/komorebi_math/generating/portable.py`, lines 145-158. Represented class: `src/komorebi_math/generating/budget.py`, lines 16-141. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.27 `generating.carry_layer_convolution`

Record G-C27. Codec version 1. Represented type: `komorebi_math.generating.masks.CarryLayerConvolution`.

The decoder enforces all six fields, checks modulus equals prime raised to exponent, and checks every layer sum is a canonical residue. The input sequences that produced the sums are absent. The decoder therefore does not independently recompute that convolution.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`exponent`	`int`
`factorial_power`	`int`
`index`	`int`
`layer_sums`	`tuple[int; length=2]`
`modulus`	`int`
`prime`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.carry_layer_convolution.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `64dc2c8dd47ecf44daee6718837250508b902a92e4081e8f2e9be2d89d53fe7c`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 477-484. Decoder: `src/komorebi_math/generating/portable.py`, lines 313-336. Represented class: `src/komorebi_math/generating/masks.py`, lines 516-529. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.28 `generating.cartier_automaton`

Record G-C28. Codec version 1. Represented type: `komorebi_math.generating.cartier.CartierAutomaton`.

After exact field matching and integer conversion, the decoder checks a nonempty transition table, valid start state, output count, digit-row lengths and in-range transition targets. These are finite structural checks. The defining rational-mask relation is not fully recertified by this decoder; run the appropriate automaton certificate separately.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`degree_bound`	`int`
`denominator`	`tuple[int; length=2]`
`numerator`	`tuple[int; length=2]`
`outputs`	`tuple[int; length=5]`
`prime`	`int`
`start_state`	`int`
`state_members`	`tuple[tuple; length=5]`
`state_numerators`	`tuple[tuple; length=5]`
`transitions`	`tuple[tuple; length=5]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.cartier_automaton.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `1a96f38dbf1b620b5ad522ed084fce2ebec408d4c4dca01438f953582dc9fd44`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 430-440. Decoder: `src/komorebi_math/generating/portable.py`, lines 214-255. Represented class: `src/komorebi_math/generating/cartier.py`, lines 155-211. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.29 `generating.cartier_linear_representation`

Record G-C29. Codec version 1. Represented type: `komorebi_math.generating.cartier.CartierLinearRepresentation`.

The decoder checks exact fields, the start-vector dimension, one transition matrix per radix digit and square matrix dimensions. It preserves the compiled representation. These checks alone are not an independent derivation of the matrices from numerator and denominator.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`degree_bound`	`int`
`denominator`	`tuple[int; length=2]`
`numerator`	`tuple[int; length=2]`
`output_scale`	`int`
`prime`	`int`
`start_vector`	`tuple[int; length=2]`
`transition_matrices`	`tuple[tuple; length=3]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.cartier_linear_representation.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `b01776df61e88540ef7624c0537e4433f36ac8e4be68e627166e3ed1eee12419`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 449-457. Decoder: `src/komorebi_math/generating/portable.py`, lines 259-296. Represented class: `src/komorebi_math/generating/cartier.py`, lines 432-481. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.30 `generating.finite_mask_carry_plan`

Record G-C30. Codec version 1. Represented type: `komorebi_math.generating.masks.FiniteMaskCarryPlan`.

Only radix and mask are serialized. The carry bound and matrices are deliberately not encoded. The decoder re-runs compile_finite_mask_carry_plan, regenerating derived state using the implementation defaults. This is a reconstruction-by-compilation codec, not a field-for-field dump of the Python object.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`mask`	`tuple[Fraction; length=3]`
`radix`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.finite_mask_carry_plan.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `32b3461540b5d8e5b7cd208ece5b047941afdf635dc583a92bf41f88ff3774d9`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 422-422. Decoder: `src/komorebi_math/generating/portable.py`, lines 298-301. Represented class: `src/komorebi_math/generating/masks.py`, lines 195-270. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.31 `generating.finite_normalized_series`

Record G-C31. Codec version 1. Represented type: `komorebi_math.generating.finite_series.FiniteNormalizedSeries`.

Basis must be a BasisDescriptor, domain a descriptor mapping and budget a GeneratingBudget. The decoder reconstructs the declared coefficient domain and finite series. Domain normalization and series construction remain responsible for coefficient validity and relevant resource checks.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`basis`	`komorebi_math.generating.basis.BasisDescriptor`

Field	Form in the finite fixture
budget	komorebi_math.generating.budget.GeneratingBudget
coefficients	tuple[int; length=3]
domain	mapping[2 entries]

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.finite_normalized_series.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `54dc118e4a9cb6c12f62824bd3981e749fa846c18b9caa57d514a3dbffe0b8c4`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 394-399. Decoder: `src/komorebi_math/generating/portable.py`, lines 172-189. Represented class: `src/komorebi_math/generating/finite_series.py`, lines 93-448. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.32 `generating.formal_series`

Record G-C32. Codec version 1. Represented type: `komorebi_math.generating.series.FormalSeries`.

The decoder requires a basis descriptor and a nonempty exact coefficient list. A callback-defined basis embedded in a finite series can be replaced by a finite table descriptor. This captures only the requested degree prefix, not the original callable.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
basis	komorebi_math.generating.basis.BasisDescriptor
coefficients	tuple[Fraction; length=3]

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.formal_series.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `5972ed8219f7240c1d59ea68e001fee138bbfd5c033749493d7259b426a9a867`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 383-386. Decoder: `src/komorebi_math/generating/portable.py`, lines 161-169. Represented class: `src/komorebi_math/generating/series.py`, lines 52-321. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.33 `generating.frozen_function`

Record G-C33. Codec version 1. Represented type: `komorebi_math.generating.portable.FrozenGeneratingFunction`.

The frozen function stores a name, basis name, finite normalization, finite coefficients, source kind and portable metadata. Constructor checks include equal lengths, a leading normalization of one and nonzero normalization values. Its series method rejects degrees beyond the capture. The original provider callback is not restored.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`basis_name`	`str`
`coefficients`	`tuple[Fraction; length=5]`
`metadata`	`mapping[2 entries]`
`name`	`str`
`normalization`	`tuple[Fraction; length=5]`
`source_kind`	`str`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.frozen_function.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `2b0e4024ae31f72fa91e09de6ea6d2828fda8259eb5592c1702e42f48f893a63`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 407-414. Decoder: `src/komorebi_math/generating/portable.py`, lines 191-211. Represented class: `src/komorebi_math/generating/portable.py`, lines 32-87. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.34 `generating.kummer_layer_distribution`

Record G-C34. Codec version 1. Represented type: `komorebi_math.generating.masks.KummerLayerDistribution`.

The decoder recomputes kummer_layer_distribution from the stored index and prime, then compares the supplied counts against that result. This is a stronger finite check than merely accepting the stored count vector.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`counts`	`tuple[int; length=1]`
`index`	`int`
`prime`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.kummer_layer_distribution.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `746bba8b87dd1a8aca5fcc8f101c063889255a4a1fb14bb0a74e74507267f324`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 465-469. Decoder: `src/komorebi_math/generating/portable.py`, lines 304-310. Represented class: `src/komorebi_math/generating/masks.py`, lines 384-419. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.35 `generating.weighted_monomial_basis`

Record G-C35. Codec version 1. Represented type: `komorebi_math.generating.basis.WeightedMonomialBasis`.

Only a BasisDescriptor is encoded. A raw callback basis without a descriptor is rejected by require_descriptor with ValueError. A declared finite table descriptor or supported declarative basis is reconstructed through the closed basis factory.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`descriptor`	`komorebi_math.generating.basis.BasisDescriptor`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/generating.weighted_monomial_basis.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `2f0dd6f843b4b22ca0e1586676c09e7436c98890dcdf37d4bb0b4b5a9b927ecc`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/generating/portable.py`, lines 358-358. Decoder: `src/komorebi_math/generating/portable.py`, lines 139-142. Represented class: `src/komorebi_math/generating/basis.py`, lines 77-245. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.36 `nonlinear.filtered_spectral_sequence_result`

Record G-C36. Codec version 1. Represented type: `komorebi_math.nonlinear.filtered.FilteredSpectralSequenceResult`.

Pages are nested records. The two degree-to-dimension mappings have integer keys and values after decoding, and the certificate is retained. The original filtered complex and differential are not stored in this result codec, so reconstruction is not a new spectral-sequence computation.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`certificate`	`komorebi_math.certificates.Certificate`
`limiting_dimensions`	`mapping[1 entries]`
`pages`	`tuple[SpectralSequencePage; length=1]`
`total_cohomology_dimensions`	`mapping[1 entries]`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.filtered_spectral_sequence_result.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `8502c4c637162187bdf7165e7ab6ec8dfe9d6a9edc1269f01c8567af8c3d9866`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 449-454. Decoder: `src/komorebi_math/export/persistence.py`, lines 455-460. Represented class: `src/komorebi_math/nonlinear/filtered.py`, lines 599-607. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.37 `nonlinear.finite_lift_tree`

Record G-C37. Codec version 1. Represented type: `komorebi_math.nonlinear.lifting.FiniteLiftTree`.

Prime and finite levels are retained; nodes are nested LiftTreeNode records. The result is a finite tree, not an infinite compatible lifting tower. Extra fields are ignored by this decoder.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`levels`	`tuple[tuple; length=2]`
`prime`	`int`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.finite_lift_tree.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `86abe3f2781a838b6708638842bfc441544377b669824a744e3179460a05705a`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 397-397. Decoder: `src/komorebi_math/export/persistence.py`, lines 398-398. Represented class: `src/komorebi_math/nonlinear/lifting.py`, lines 385-417. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.38 `nonlinear.lift_tree_node`

Record G-C38. Codec version 1. Represented type: `komorebi_math.nonlinear.lifting.LiftTreeNode`.

Value coordinates, depth and a non-null parent_index are converted to integers. The parent may be null for a root. This record alone has no parent tree against which every link can be checked.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`depth`	`int`
`parent_index`	`null`
`value`	`tuple[int; length=1]`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.lift_tree_node.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `61b4dfc45b61f1c49cb642a6977db5808e43ad017862b08dd4df18e655b2150f`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 381-385. Decoder: `src/komorebi_math/export/persistence.py`, lines 386-390. Represented class: `src/komorebi_math/nonlinear/lifting.py`, lines 376-382. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.39 `nonlinear.ordered_rooted_tree`

Record G-C39. Codec version 1. Represented type: `komorebi_math.nonlinear.trees.OrderedRootedTree`.

Children are recursively encoded tree records and reconstructed as a tuple of children. This represents a finite ordered rooted tree. The generic recursion-depth limit still applies to deeply nested trees.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`children`	`tuple[OrderedRootedTree; length=2]`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.ordered_rooted_tree.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `d91880c6db4ef74758d79b474ea8866ac3fe110591544b5d2fe32ab564cf6533`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 282-282. Decoder: `src/komorebi_math/export/persistence.py`, lines 283-283. Represented class: `src/komorebi_math/nonlinear/trees.py`, lines 97-174. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.40 `nonlinear.packet_jet_address`

Record G-C40. Codec version 1. Represented type: `komorebi_math.nonlinear.jets.PacketJetAddress`.

The output label is converted to str and input labels to a tuple. The address describes an ordered packet block. It contains neither projection matrices nor a derivative provider.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`inputs`	`tuple[str; length=2]`
`output`	`str`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.packet_jet_address.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `2860344375e9f1f64972222b4afb6359499de8ff630886ffcd6d7ad994cfb29b`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 290-290. Decoder: `src/komorebi_math/export/persistence.py`, lines 291-291. Represented class: `src/komorebi_math/nonlinear/jets.py`, lines 55-67. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.41 `nonlinear.packet_jet_coefficient`

Record G-C41. Codec version 1. Represented type: `komorebi_math.nonlinear.snapshots.PacketJetCoefficient`.

Indices and value become tuples. Their association with a source dimension, target dimension and jet order is checked only when an enclosing snapshot or stream supplies that context. A standalone coefficient record is not that enclosing contract.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`indices`	`tuple[int; length=2]`
`value`	`tuple[Fraction; length=1]`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.packet_jet_coefficient.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `33d3bf06c16b86763678827acfc5deafb304d324f9dc661a1365f6f141daedf3`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 298-298. Decoder: `src/komorebi_math/export/persistence.py`, lines 299-299. Represented class: `src/komorebi_math/nonlinear/snapshots.py`, lines 71-76. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.42 `nonlinear.packet_jet_snapshot`

Record G-C42. Codec version 2. Represented type: `komorebi_math.nonlinear.snapshots.PacketJetSnapshot`.

Version 2 stores provider under the key provider and requires coefficient_ordering to equal lexicographic. Address, dimensions, point, sparse coefficients, exactness and capture_certificate define a fixed finite snapshot. Version 1 used provider_name and no ordering field; the sole built-in migration supplies the current representation. The captured certificate is retained, not independently re-proved.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`address`	`komorebi_math.nonlinear.jets.PacketJetAddress`

Field	Form in the finite fixture
capture_certificate	komorebi_math.certificates.Certificate
coefficient_ordering	str
coefficients	tuple[PacketJetCoefficient; length=1]
exactness	str
point	tuple[int; length=2]
provider	str
source_dimension	int
target_dimension	int

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.packet_jet_snapshot.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `aeec4f5e898932b67a9bb04f3d1fb99d088baef324db101554efcb68eb2cb559`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. Version 1 is accepted only through the committed 1-to-2 migration described in G.5. Re-encoding uses version 2.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 306-316. Decoder: `src/komorebi_math/export/persistence.py`, lines 233-250. Represented class: `src/komorebi_math/nonlinear/snapshots.py`, lines 79-277. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.43 `nonlinear.sparse_symmetric_tensor`

Record G-C43. Codec version 1. Represented type: `komorebi_math.nonlinear.sparse.SparseSymmetricTensor`.

The tensor stores order, dimensions and finite entries. Each entry carries output, inputs and value. Index fields are converted to integers before construction. It is a finite sparse tensor, not a callback or an unbounded multilinear operator.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
entries	tuple[dict; length=1]
order	int
source_dimension	int
target_dimension	int

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.sparse_symmetric_tensor.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `a3558542088fbbfc0efb3caa9924e49715ac58916467f7962844dc23ee5ec354`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 341-353. Decoder: `src/komorebi_math/export/persistence.py`, lines 354-366. Represented class: `src/komorebi_math/nonlinear/sparse.py`, lines 98-341. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.44 `nonlinear.spectral_sequence_entry`

Record G-C44. Codec version 1. Represented type: `komorebi_math.nonlinear.filtered.SpectralSequenceEntry`.

All seven page/degree/dimension/rank fields are converted to integers. The record is the reported entry of a finite page. It does not contain differentials needed to recompute ranks.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`complementary_degree`	`int`
`dimension`	`int`
`filtration_degree`	`int`
`incoming_rank`	`int`
`outgoing_rank`	`int`
`page`	`int`
`total_degree`	`int`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.spectral_sequence_entry.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `471129223f38760b451ee61f80ce0b80c997e00d79a0ebb15a392908fa1e361a`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/export/persistence.py`, lines 405-413. Decoder: `src/komorebi_math/export/persistence.py`, lines 414-422. Represented class: `src/komorebi_math/nonlinear/filtered.py`, lines 559-570. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.45 `nonlinear.spectral_sequence_page`

Record G-C45. Codec version 1. Represented type: `komorebi_math.nonlinear.filtered.SpectralSequencePage`.

The page number, total dimension and total differential rank become integers; entries and certificate are nested records. Loading does not rebuild the original filtered complex. Additional data fields are ignored.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`certificate`	`komorebi_math.certificates.Certificate`
`entries`	`tuple[SpectralSequenceEntry; length=1]`
`page`	`int`
`total_differential_rank`	`int`
`total_dimension`	`int`

Read policy. Extra decoded data fields are accepted and discarded. This codec does not check an exact data-key set. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/nonlinear.spectral_sequence_page.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `8fd4ea1f41e81e28038cce207cff3023`

82fac32fba4c50c9418817f073784e7c. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: src/komorebi_math/export/persistence.py, lines 429-435. Decoder: src/komorebi_math/export/persistence.py, lines 436-442. Represented class: src/komorebi_math/nonlinear/filtered.py, lines 573-596. Full source and fragment hashes are in Block39_Portable_Schema_Records.json.

G.7.46 refinement.lattice_polyphase

Record G-C46. Codec version 1. Represented type: komorebi_math.refinement.polyphase.LatticePolyphaseRefinement.

Coarse and fine stride tuples are converted to integers. The constructor enforces the finite refinement relation. Persisting the refinement records an address-system relationship rather than materializing all refined signal data.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
coarse_strides	tuple[int; length=2]
fine_strides	tuple[int; length=2]

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: block39-fixtures/refinement.lattice_polyphase.canonical.json. The pretty fixture has the same payload. Payload SHA-256: 91a98988d0e04d16294337da933f4f77b46f693b0641295c33871b249a9a8d22. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: src/komorebi_math/refinement/portable.py, lines 168-171. Decoder: src/komorebi_math/refinement/portable.py, lines 84-90. Represented class: src/komorebi_math/refinement/polyphase.py, lines 670-914. Full source and fragment hashes are in Block39_Portable_Schema_Records.json.

G.7.47 refinement.polyphase

Record G-C47. Codec version 1. Represented type: komorebi_math.refinement.polyphase.PolyphaseRefinement.

The two orders define the finite coarse-to-fine refinement, with divisibility and positive-order conditions delegated to the constructor. No signal values are included in this tag.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
coarse_order	int
fine_order	int

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/refinement.polyphase.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `40542e7310863ff33eda20906a31533e0483d24a5363f18ff2c64c847dee0e8f`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/refinement/portable.py`, lines 149-152. Decoder: `src/komorebi_math/refinement/portable.py`, lines 73-76. Represented class: `src/komorebi_math/refinement/polyphase.py`, lines 129-494. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.48 `refinement.polyphase_tower`

Record G-C48. Codec version 1. Represented type: `komorebi_math.refinement.polyphase.PolyphaseRefinementTower`.

The ordered refinement levels are an integer tuple. The tower is finite and does not assert an infinite limiting refinement. Its ordering and adjacent relation are constructor-level concerns.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`orders`	`tuple[int; length=3]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/refinement.polyphase_tower.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `b1112a304e55a98af630be3169e2b53846f362d4bb4e8ce8d64643896b79598f`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/refinement/portable.py`, lines 160-160. Decoder: `src/komorebi_math/refinement/portable.py`, lines 79-81. Represented class: `src/komorebi_math/refinement/polyphase.py`, lines 497-667. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.49 `refinement.residue_coordinates`

Record G-C49. Codec version 1. Represented type: `komorebi_math.refinement.residue.ResidueCoordinates`.

The modulus and finite length become integers; channels remain portable numeric arrays. The represented finite sequence can be reconstructed from those lanes. Original array strides, memory sharing and device placement are not persistence guarantees.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`channels`	`tuple[ndarray; length=3]`
`length`	`int`
`modulus`	`int`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/refinement.residue_coordinates.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `6b8b954c099b99c53e0bb4508a1e0ae2a1644d2ec0cce90bd9cbaef62cf88b16`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/refinement/portable.py`, lines 125-129. Decoder: `src/komorebi_math/refinement/portable.py`, lines 53-60. Represented class: `src/komorebi_math/refinement/residue.py`, lines 55-102. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.50 `signals.lattice_polyphase_coordinates`

Record G-C50. Codec version 1. Represented type: `komorebi_math.signals.polyphase.LatticePolyphaseCoordinates`.

Channels are a mapping keyed by integer address tuples. Strides and original shape are converted to integer tuples. Reconstruction is finite; sparse addresses, shapes and channel values are interpreted by LatticePolyphaseCoordinates, not by an implicit external lattice source.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`channels`	`mapping[4 entries]`
`original_shape`	`tuple[int; length=2]`
`strides`	`tuple[int; length=2]`

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/signals.lattice_polyphase_coordinates.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `9243e01023a8aeaeed53a18111765666a8665f371376cca2fe1c037e7493cfcc`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/refinement/portable.py`, lines 113-117. Decoder: `src/komorebi_math/refinement/portable.py`, lines 36-50. Represented class: `src/komorebi_math/signals/polyphase.py`, lines 293-377. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.7.51 `signals.polyphase_coordinates`

Record G-C51. Codec version 1. Represented type: `komorebi_math.signals.polyphase.PolyphaseCoordinates`.

Channels are tuples of ndarrays, with integer order and axis and a finite original_shape. The record preserves finite channel values and array dtypes. It does not promise preservation of memory views, contiguity, original strides or a CUDA allocation.

Complete decoded encoder data. The fixture forms below are examples, not a closed type specification for arbitrary inputs. Each row is a required data key.

Field	Form in the finite fixture
`axis`	`int`
`channels`	`tuple[ndarray; length=3]`
`order`	`int`
`original_shape`	`tuple[int; length=2]`

Field	Form in the finite fixture

Read policy. Extra decoded data fields are rejected by the decoder. Exact field coverage does not imply strict numeric or boolean type checking. Missing fields were individually rejected in the version-bound tests. Extra outer tagged-wrapper fields and future versions were also rejected.

Canonical JSON and digest. Complete compact UTF-8 envelope: `block39-fixtures/signals.polyphase_coordinates.canonical.json`. The pretty fixture has the same payload. Payload SHA-256: `dd353f482582ebce5c370de8bebae72a97f3eab5f9060262bb3c138d35b3c37b`. Both forms reconstruct the represented type; the finite fixture re-encodes identically.

Migration. No older-version migration ships for this tag. Current version 1 is the supported frozen form; a future version is rejected.

Source binding. Encoder: `src/komorebi_math/refinement/portable.py`, lines 100-105. Decoder: `src/komorebi_math/refinement/portable.py`, lines 25-33. Represented class: `src/komorebi_math/signals/polyphase.py`, lines 37-129. Full source and fragment hashes are in `Block39_Portable_Schema_Records.json`.

G.8 Packet-jet stream directory schemas

The directory format is separate from `komorebi-math.portable`. It has a `manifest.json`, a `chunks` directory, and canonical chunk filenames such as `chunk-00000000.json`. Incomplete writes use `<destination>.partial`. A completed, verified staging directory is promoted to the requested destination. A crash can leave uncommitted files; resume verifies the committed prefix before continuing. This is not a database transaction or a guarantee against arbitrary concurrent filesystem modification.

The manifest schema is `komorebi-math.packet-jet-stream`, version 1. The chunk schema is `komorebi-math.packet-jet-stream.chunk`, version 1. Both envelopes have **four** keys: `schema`, `schema_version`, `payload_sha256`, `payload`. Unlike the single-document portable envelope, they do not have a producer field at the envelope level. The manifest payload carries `producer_version`.

Manifest payload field matrix.

Field	Meaning
`state`	`in_progress` or `complete`.
`producer_version`	Recorded package producer.
`metadata`	Address, dimensions, provider, exactness, point, tolerance, dense count, capture mode and source digest.
`metadata_sha256`	Canonical digest of the metadata object.
`chunk_size`	Positive configured chunk size. Its meaning differs between direct and snapshot capture.
`evaluations_completed`	Covered dense-basis progress.
`coefficients_completed`	Number of stored finite coefficient records.
`maximum_omitted_basis_norm`	Nonnegative bound retained from capture.
`chunks`	Ordered index records with contiguous basis and coefficient ranges.
`capture_certificate`	Null during an incomplete capture; nested portable certificate when complete.
`stream_sha256`	Content digest binding the declared stream composition.

Metadata field matrix.

Field	Meaning
`address`	Nested portable PacketJetAddress.
`source_dimension` / `target_dimension`	Positive finite dimensions.

Field	Meaning
`provider_name`	Descriptive provider label. This differs from the v2 single-snapshot codec key `provider`.
`exactness`	Exactness label retained from the capture.
`point`	Portable tuple whose length matches the source dimension.
`tolerance`	Finite nonnegative capture tolerance.
`dense_coefficient_count`	Source dimension raised to address order.
`capture_mode`	`direct` or `snapshot`.
`source_digest`	Source identity digest used for resume matching.

Each chunk index record has exactly `index`, `filename`, `basis_start`, `basis_stop`, `coefficient_start`, `coefficient_stop`, `payload_sha256`, `byte_count`. The filename must be precisely the zero-padded spelling for that index. Noncanonical filenames, including traversal paths, are rejected. Basis and coefficient intervals are nondecreasing and must form contiguous committed progress. Digests must have the expected lowercase hexadecimal form.

A chunk payload has exactly `index`, `basis_start`, `basis_stop`, `coefficient_start`, `coefficient_stop`, `coefficients`. Each coefficient has exactly `indices`, `value`: indices are a JSON array and the value is a portable-encoded tuple. Decoding checks order, source-index range and target-vector length. Chunk envelopes and the manifest's chunk records are cross-checked, not interpreted as unrelated JSON files.

Progress semantics. Direct capture counts dense-basis evaluations, even where a resulting coefficient is omitted as zero. Its chunks cover basis ranges. Snapshot capture writes already selected coefficients; incomplete snapshot chunks do not yet claim dense-basis completion, and its final chunk closes that coverage. A complete manifest requires the full dense count and a capture certificate. An in-progress manifest cannot claim a final certificate.

`open_packet_jet_snapshot_stream` rejects incomplete input by default. `allow_incomplete=True` makes that state explicit. A partial range evaluation remains partial even if its local integrity check succeeds. Selection and full snapshot materialization can impose a maximum coefficient count. They are not equivalent to limiting an arbitrary input file's size before parsing it.

Executed finite example. The stream replay uses a two-dimensional quadratic jet with one-dimensional output. It pauses and resumes both capture modes, verifies chunks, loads a full snapshot, and compares streamed evaluation with the live jet. Splitting the stored coefficient range yields two explicitly partial evaluations whose sum matches the full result. The replay covers ten named checks. Corruption, missing chunks, noncanonical filenames, changed resume metadata, missing required fields and exhausted materialization bounds are separate rejection tests.

The source dimension raised to derivative order is still the dense-basis count. Chunking bounds the working set for normal generated chunks but does not remove that combinatorial cost or establish a hostile-input resource boundary. All stream observations here are finite CPU tests, not CUDA or native Windows qualification.

G.9 Reproducible recipes and reference files

From a working copy of the delivered root, install the pinned wheel into a separate environment with its required dependencies. The examples below use the active interpreter; they do not download dependencies and do not silently select the source checkout.

```
python tools/block39/inventory.py
python tools/block39/stream_lab.py --output scratch-stream-replay
python -I -m pytest tools/block39 -p no:cacheprovider
python tools/block39/generate_manual.py
python tools/block39/build_pdfs.py
```

The inventory generator refuses a source-checkout import and compares every package-source/data file with the installed package. Use a new stream output directory for each active replay; existing evidence is not silently overwritten. Test, PDF and manifest receipts are bound to file hashes. Regenerating a document or running a new test command in a copy does not update an already sealed delivery's validation claim.

A minimal safe round-trip for trusted locally created finite data is:

```
from fractions import Fraction
from komorebi_math.export import save_portable, load_portable

value = {"ratio": Fraction(2, 7), "prefix": (1, 1, 2, 3)}
save_portable(value, "example.portable.json")
restored = load_portable("example.portable.json")
assert restored == value
```

An existing destination is rejected unless overwrite is explicitly allowed. This recipe checks value preservation, not a mathematical assertion embedded in the data. For migrations, retain the original file, decode through the registered chain, and write the current result to a new destination. A migration cannot be authenticated by the same unkeyed digest it can replace.

The reference ledger includes all 51 canonical envelope fixtures and their 51 pretty equivalents, 26 primitive/container/array fixtures, and one legacy snapshot-v1 fixture. Complete stream fixtures and paused manifests live with the replay evidence. JSON files are data, not executable proof certificates. Source locators and hashes provide reproducible traceability to this exact release.

G.10 Corrections, known limits and closure

The inherited package document `docs/PERSISTENCE_SCHEMAS.md` is narrower and older than this appendix. Its migration example uses the unsupported keyword `migrate`; the actual API is `migrator`. Its abbreviated envelope omits the mandatory `producer_version`. Its enumerated mathematical codec list covers only the early core codecs, not all 51 frozen entries. This appendix explicitly supersedes those points while retaining the unchanged R2 package document as historical release content.

Several input-validation weaknesses were reproduced and documented rather than silently changed: producer metadata is unchecked; outer schema-version equality accepts a boolean; integral floats can pass codec-version checks; integer conversion can truncate fraction data and array dimensions; certificate flags use truthiness; twelve codecs ignore extra data fields; and not every ndarray dtype round-trips. The generic loader has no universal byte/allocation cap. These are remaining hardening opportunities, not successful security qualifications.

Do not treat a passing schema-reference test for a permissive behavior as an endorsement of that behavior. The expected-outcome tests make the limitation visible so a later implementation repair cannot silently change the documented contract. A stricter future release should define its compatibility policy, update the relevant fields/versions where appropriate, and rerun malformed-input and legacy migration tests.

Executed checks for this edition. The unchanged package source suite passed 1,203 tests. The installed-wheel schema-reference suite passed 663 tests, including all codec routes, required-field removal cases, future-version rejections, scalar/container fixtures, migration cases and stream boundaries. The ten stream replay checks repeat part of this behavioral area and are not ten additional mathematical theorems. All 366 installed package files match the stored source. The reference does not turn serialized claims into Lean proofs.

Reference boundaries. This source-bound portable-schema and migration reference does not certify every dtype, custom codec, input size, malicious payload or platform. The recorded audit did not qualify native Windows/PowerShell, other Python versions, CUDA, strict MkDocs, fully dependency-isolated installation or final publication. Appendix O distinguishes the final source's retained execution evidence from this predecessor audit.

Appendix H. Certificate and theorem-ID index

Start with the result you have. If a computation returned a certificate, read H.2 and the matching type in H.4 before looking up its theorem label. If you already have a label and need its producer, use H.7, then follow the symbol into H.8. H.9 helps when the certificate is nested inside a larger result object.

A practical reading order. Identify the result type; check whether its reported validity meets your task; read its exactness class and unchecked assumptions; then inspect the residuals, tolerance and finite range used by the producer. Preserve those details when recording the answer. A useful report says what was computed, on which inputs and domain, and under which assumptions, rather than quoting only a Boolean.

For example, the finite-prefix certificates described below carry an audit degree or a last checked index. Include that boundary in your description of a successful result. If the certificate is conditional, the unchecked assumptions remain part of the result even when its validity check succeeds. H.3 explains how those assumptions propagate through a composed computation.

H.1 Purpose and scope

This appendix connects a recorded theorem label to its implementation symbol, declared hypotheses, certificate fields and example evidence. It covers the pinned `1.0.0b4-block36-r2` source, not all possible downstream extensions. Its source vocabulary is finite; the runtime label namespace is not. A caller can supply a new string, compose existing strings, or load one from a portable file.

The word *certificate* is not a uniform proof protocol in this release. The base `Certificate` is a stored validation record. Some specialized records compute a Boolean from stored sides or a failure list. Others wrap a base record, and `Basis Certificate` supplies diagnostics without `valid` or `require`. The type inventory below preserves those differences.

Three axes must be read independently:

Axis	Question answered	What it does not establish
Runtime validity	Did the producer or stored field report success?	The validity flag is not independently recomputed by the base `require`.
`Exactness`	How did the producer classify its calculation or assumptions?	An exact finite calculation does not establish an unbounded theorem.
`ClaimStatus` provenance	How is the attached source claim classified by its author?	A `PROVED` record is metadata, not evidence of a Lean check in this reference.

API stability from Appendices A-C is a fourth, separate axis. A stable callable can produce a numerical certificate. A research callable can perform exact rational arithmetic. A label containing `T` is not a theorem-proof count, and the occurrence of a source-paper name is not a checked cross-reference to the current separate PRSC paper series.

All source locators are relative to the delivered root. Constructor references `H-C...` address the construction-site matrix and JSON ledger. Label references `H-T...` are local index keys, not new theorem names. Their numbering belongs to this edition. Use the literal theorem label together with the qualified symbol and pinned source digest for durable identification. `EX-E-...` identifies the unchanged example record in Appendix E.

The JSON index contains the complete expressions, source fragments, hashes, constructor fields, specialized types, typed carriers, provenance records and literal references. Printed cells abbreviate long code expressions for legibility. Ellipses in a printed expression never replace the complete machine-readable record. The installed-wheel crosswalk is a separate observation ledger so a static reference cannot accidentally become an execution claim.

H.2 The base record and result wrappers

`Certificate` has nine fields: `valid`, `exactness`, `residuals`, `tolerance`, `assumptions_checked`, `assumptions_unchecked`, `diagnostics`, `theorem_id` and `message`. Only the first two are required by its generated initializer. Type annotations describe the intended interface; the base dataclass has no post-initialization validator enforcing every field's type or mathematical consistency.

The implementation of `Certificate.require()` is a truthiness check. It raises `ValidationError` when `valid` is false and otherwise returns the same record. It does not compare residuals against tolerance, recompute a witness, reject unchecked assumptions, require exact arithmetic, look up the theorem label, or invoke a proof kernel. A manually supplied truthy string such as `"false"` can therefore pass this method. These are reproduced interface limits, not a recommendation to construct such records.

The dataclass is frozen only at the outer field-assignment level. Its residual and diagnostic dictionaries remain mutable. `to_dict()` constructs a dataclass-derived representation and emits the enum value. `to_json()` uses a presentation serialization with a string fallback. That presentation is not the portable persistence envelope from Appendix G and is not a signed proof artifact.

`ComputationResult.require()` delegates to its certificate and returns the *value*, not the record. Its `valid` property mirrors the validity flag. Its `exact` property tests whether the status is `Exactness.EXACT`; it can therefore be true for an invalid record. Always inspect validity separately. A successful conditional result can also pass `require()` while retaining unchecked assumptions.

`ConditionalResult` enforces that its certificate's exactness is the conditional enum member. It does not, by that check alone, require validity, prove assumptions or enforce a nonempty unchecked list. Treat the wrapper as a representation constraint rather than an admission gate.

A normal local inspection pattern is:

```
certificate = result.certificate
certificate.require()
print(certificate.exactness.value)
print(certificate.assumptions_unchecked)
print(certificate.residuals, certificate.tolerance)
print(certificate.theorem_id)
```

The producer's input validation, arithmetic backend, finite range and witness computation still determine the conclusion. Reading these fields is not a substitute for those checks.

H.3 Composition, assumptions and numerical evidence

The expression subsystem supplies a stricter *composition* operation, not a general proof checker. Its declared weakening order is exact, numerical, conditional, heuristic, then planned. `weakest_exactness` requires enum instances, selects the weakest supplied status, and returns exact for an empty input by convention. This is an implementation ordering for evidence aggregation, not a claim that all notions of evidence form a universal mathematical hierarchy.

`compose_certificates` requires base certificate instances. It preserves child residuals under `child0:`, `child1:` and subsequent prefixes, separates child/local diagnostics, retains child theorem IDs in the diagnostic record, and uses the maximum supplied finite nonnegative tolerance. It checks residuals for finite real values. It does not independently retest each residual against a tolerance or establish that the arithmetic behind a child was correct.

Unchecked assumptions dominate checked assumptions with the same text. A nonempty unchecked set downgrades otherwise exact or numerical evidence to conditional. A false child flag makes the aggregate invalid. The empty composition is a valid exact record with zero children by convention; it is not a new proof of any caller-chosen theorem label. Labels passed to this composition helper must be nonempty strings when supplied, unlike the unconstrained base initializer.

`exact_internal_certificate` records an internal operation declared exact by construction. It validates the description, label and diagnostic form. It does not execute or verify an arbitrary mathematical proposition supplied as text. The operation that calls it remains responsible for its finite construction.

For numerical producers, inspect the actual residual norm, scaling factor, rank threshold and input domain. Two producers can share a theorem label yet check different residuals. Backend-dependent producers can emit exact or numerical status through the same construction site. A zero floating residual is not automatically an exact symbolic identity, and a tolerance is not automatically a theorem-level error bound.

H.4 Specialized certificate records

The following cards give the full declared field lists. Method descriptions distinguish stored flags, computed comparisons and nested base records. Their source fragments, including the exact `valid`, `require` and `certificate` methods where present, are retained in the JSON index.

BlockJacobiCertificate

`komorebi_math.algorithms.krylov.BlockJacobiCertificate`. Source: `algorithms/krylov.py:396`.

A result carrier for the packet diagonal, normalized coupling, eta and an optional condition bound. Inspect its nested `certificate`. It does not expose the base require protocol directly. The producer checks positive definiteness and coupling conditions; the record itself is not a new proof of those inputs.

Field	Annotation and default
`diagonal`	`BlockDiagonalOperator; [required]`
`normalized_coupling`	`Array; [required]`
`eta`	`float; [required]`
`condition_bound`	`float | None; [required]`
`certificate`	`Certificate; [required]`

Certificate

`komorebi_math.certificates.Certificate`. Source: `certificates.py:28`.

The base record described in H.2. Its require method returns itself, and its validity field is stored rather than recomputed.

Field	Annotation and default
`valid`	`bool; [required]`
`exactness`	`Exactness; [required]`
`residuals`	`dict[str, float]; field(default_factory=dict)`
`tolerance`	`float | None; None`
`assumptions_checked`	`tuple[str, ...]; ()`
`assumptions_unchecked`	`tuple[str, ...]; ()`
`diagnostics`	`dict[str, Any]; field(default_factory=dict)`
`theorem_id`	`str | None; None`
`message`	`str; ''`

StateSpaceCoordinateCertificate

`komorebi_math.coordinates.state_space.StateSpaceCoordinateCertificate`. Source: `coordinates/state_space.py:259`.

Stores a validity flag along with systems, a state transform and a finite Markov-parameter count. Its certificate method wraps that flag with label `CC.R3`. Calling the wrapper does not rerun the original transfer-invariance computation.

Field	Annotation and default
`source`	`StateSpaceModel; [required]`

Field	Annotation and default
`target`	`StateSpaceModel; [required]`
`transform`	`CoordinateTransform; [required]`
`markov_count`	`int; [required]`
`valid`	`bool; [required]`

BasisCertificate

`komorebi_math.generating.basis.BasisCertificate`. Source: `generating/basis.py:66`.

A finite basis diagnostic with two separate Boolean diagnostics, denominator and bit-size observations. There is no generic valid property and no require method. Do not coerce all fields into an invented all-purpose pass/fail result.

Field	Annotation and default
`name`	`str; [required]`
`degree`	`int; [required]`
`nonzero_normalization`	`bool; [required]`
`integral_structure_constants`	`bool; [required]`
`maximum_denominator`	`int; [required]`
`maximum_numerator_bits`	`int; [required]`

PointedSubindexCertificate

`komorebi_math.generating.bell.PointedSubindexCertificate`. Source: `generating/bell.py:115`.

Computes valid by comparing the stored left and right sides. Require returns None on success and raises on a mismatch. The certificate method emits a base record with `NGF.POINTED_SUBINDEX`. Direct construction with equal sides does not independently verify primality or regenerate the combinatorial sides.

Field	Annotation and default
`index`	`int; [required]`
`prime`	`int; [required]`
`left`	`tuple[int, ...]; [required]`
`right`	`tuple[int, ...]; [required]`

AutomatonCertificate

`komorebi_math.generating.cartier.AutomatonCertificate`. Source: `generating/cartier.py:136`.

Computes valid from an empty finite discrepancy list. Require returns None or raises on the first stored discrepancy. The compared_terms field limits the recorded audit; it is not an all-indices automaton proof.

Field	Annotation and default
`compared_terms`	`int; [required]`
`failures`	`tuple[tuple[int, int, int], ...]; [required]`

SeriesTransferCertificate

`komorebi_math.generating.finite_series.SeriesTransferCertificate`. Source: `generating/finite_series.py:62`.

Uses its stored valid flag. Require returns None or raises, and certificate emits `NGF.UNIVERSAL_PRODUCT_AND_TRANSFER`. A manually constructed inconsistent flag/failures pair is not reconciled by these wrappers.

Field	Annotation and default
`valid`	`bool; [required]`
`degree`	`int; [required]`
`source_basis`	`str; [required]`
`target_basis`	`str; [required]`
`domain`	`str; [required]`
`failures`	`tuple[int, ...]; ()`

RationalMaskAlgebraicCertificate

`komorebi_math.generating.masks.RationalMaskAlgebraicCertificate`. Source: `generating/masks.py:754`.

Computes valid from the finite failure list, with prime and degree retained. Require returns None or raises on the first failure. Its base certificate label is `GF-RATIONAL-MASK-ALGEBRAIC`. The finite degree remains part of the conclusion.

Field	Annotation and default
`prime`	`int; [required]`
`degree`	`int; [required]`
`failures`	`tuple[tuple[int, int], ...]; [required]`

CarryLinearCertificate

`komorebi_math.generating.normalization.CarryLinearCertificate`. Source: `generating/normalization.py:56`.

Computes valid from a finite failure list for a supplied valuation callback. Require returns None or raises. The producer recovers slope/carry parameters and audits through checked_through; the unbounded classification is not proved by that finite prefix.

Field	Annotation and default
`prime`	`int; [required]`
`linear_slope`	`int; [required]`
`carry_weight`	`int; [required]`
`checked_through`	`int; [required]`
`failures`	`tuple[tuple[int, int, int, int], ...]; [required]`

GradingCertificate

`komorebi_math.nonlinear.graded.GradingCertificate`. Source: `nonlinear/graded.py:193`.

A carrier for arity, tested labels, a forbidden residual and a nested base certificate. Use the nested record. The finite tests and any assumptions on the supplied multilinear operation must be kept visible.

Field	Annotation and default
`arity`	`int; [required]`
`tested_input_labels`	`int; [required]`
`forbidden_residual`	`float; [required]`

Field	Annotation and default
`certificate`	`Certificate; [required]`

H.5 Reproduced boundaries and safe interpretation

Disabled construction validation. A packet system created from `2 * I` with `validate=False` fails its packet-axiom certificate but passes the separate self-adjointness check in `hilbert_certificate()`. The latter's checked-assumption text includes packet axioms without recomputing them in that method. The example deliberately demonstrates the caller's ability to bypass a prerequisite, not a valid packet system. The reference records that behavior without altering the frozen package bytes.

For that interface, explicitly check the packet axioms before the Hilbert refinement:

```
import numpy as np
from komorebi_math import PacketSystem

system = PacketSystem([np.diag([1, 0]), np.diag([0, 1])])
system.certificate().require()
system.hilbert_certificate().require()
```

The second call refines an already validated system. It must not be read as a replacement for the first on an unchecked object. This is one examined producer boundary, not a claim that every constructor-bypass path in the library was audited.

Stored claims and portable data. Appendix G's decoder can preserve a supplied label and use truthiness for a supplied validity flag. Neither a correct payload digest nor successful decoding authenticates the writer or re-proves the mathematical result. Rebuild a result from its mathematical inputs with the relevant producer when fresh verification is required.

Finite witnesses. Automaton, carry-linear, grading and finite-series certificates retain finite audit parameters. A finite check may validate exactly the stated finite instance while leaving a global statement unresolved. Do not remove its degree, tested range, arithmetic domain, backend or unchecked assumptions when quoting a conclusion.

Expected negative conclusions. A test can pass by correctly observing an invalid certificate. The replay includes nontrivial holonomy, hidden-feedback memory and unmet automorphic completion gates. Those outcomes remain negative conclusions for their stated checks, not successful theorem qualifications.

H.6 Provenance registry and non-unique labels

The provenance registry is keyed by qualified Python names, not by theorem label. `documented` attaches a record to an object and registers its qualified name. `register_record` replaces an existing entry under the same qualified-name key; it does not enforce globally unique theorem IDs. `records()` returns a dictionary snapshot. `describe()` retrieves attached or registered metadata, not a checked proof object.

The seven repeated labels below are retained as distinct symbol records. Reuse does not by itself establish that either source claim is false, but it makes an ID-only citation ambiguous. The canonical citation tuple for this index is `(theorem label, qualified symbol, pinned source hash)`. Metadata statuses are reproduced exactly rather than promoted or demoted by this reference.

Reused label	Separate declared titles
`KM-DSP-D05`	Finite FIR frequency response / Finite modified periodogram
`KM-DSP-D06`	Finite Welch power spectral estimate / Windowed-sinc finite FIR design
`KM-DSP-T06`	Finite centered polyphase rational-resampling identity / Finite multilevel Haar reconstruction

Reused label	Separate declared titles
PSC-II-T13	Exact separation weight from the lattice action / Gluing module and exact separation weight
PSC-III-D13	Finite ordered rooted tree / Linear correction datum and cokernel obstruction
PSC-III-T14	Cokernel obstruction criterion / Polynomial rooted-tree convergence certificate
PSC-III-T41	Finite nonlinear Schur elimination / Fundamental holonomy intertwining criterion

The loaded registry contains 198 qualified-name records and 191 distinct registered labels. Declared status totals are 28 CLASSICAL, 1 CONDITIONAL, 40 DEFINITION, 11 FINITE_CERTIFICATE, 3 HEURISTIC, 115 PROVED. These totals reproduce metadata only. They are not a count of Lean theorems or newly verified mathematical proofs.

The registry uses 99 distinct verification-suite strings. These strings are not literal CLI choices from Appendix F. They are provenance navigation labels, not automatically executable `komorebi verify` arguments. The index prints them as declared; consult the CLI matrix for actual commands.

H.7 Theorem-label and symbol index

The finite source vocabulary has **488 labels**, including definitions, diagnostic labels, verification fixtures and engineering gates. It includes explicit theorem arguments/defaults, provenance identifiers, and additional source literals in the project ID families, including table-selected and rewrite-return labels. A label mentioned only by a verification fixture remains a reference label, not an invented production theorem.

Each card distinguishes direct constructor sites from other declarations. The checked and unchecked expressions shown for direct sites are source expressions, not proof that all branches execute those checks. Full expressions are in the `constructor_sites` ledger. The absence of a runtime example observation is explicitly recorded. Literal mentions in test files are navigation, not theorem coverage.

H-T001 / CC.A0

Source symbol(s): `komorebi_math.coordinates.basis.CoordinateAtlas.resolve`. No attached provenance record under this label.

Locations: `coordinates/basis.py:348`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T002 / CC.A1

Source symbol(s): `komorebi_math.coordinates.basis.CoordinateAtlas.resolve`, `komorebi_math.coordinates.basis.CoordinateAtlas.compose_path`. No attached provenance record under this label.

Locations: `coordinates/basis.py:376`, `coordinates/basis.py:395`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** `test_coordinates_general_persistence.py`.

H-T003 / CC.A2

Source symbol(s): `komorebi_math.coordinates.basis.CommutingDiagramCheck.certificate`. No attached provenance record under this label.

Locations: `coordinates/basis.py:246`. **Direct base sites:** `H-C043`.

`H-C043`: status `Exactness.EXACT`; checked `('common source', 'common target', 'exact matrix products')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-024`. **Literal test mentions:** none recorded.

H-T004 / CC.B0

Source symbol(s): `komorebi_math.coordinates.basis.FiniteBasis.certificate`. No attached provenance record under this label.

Locations: `coordinates/basis.py:205`. **Direct base sites:** `H-C042`.

`H-C042`: status `Exactness.EXACT`; checked `('finite rational vectors', 'exact row reduction')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T005 / CC.B1

Source symbol(s): `komorebi_math.coordinates.basis.FiniteBasis`. No attached provenance record under this label.

Locations: `coordinates/basis.py:146`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T006 / CC.B2

Source symbol(s): `komorebi_math.coordinates.basis.permutation_transform`. No attached provenance record under this label.

Locations: `coordinates/basis.py:500`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T007 / CC.B3

Source symbol(s): `komorebi_math.coordinates.basis.scaling_transform`. No attached provenance record under this label.

Locations: `coordinates/basis.py:520`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T008 / CC.C1

Source symbol(s): `komorebi_math.coordinates.combinatorial.monomial_to_falling_factorial_transform`. No attached provenance record under this label.

Locations: `coordinates/combinatorial.py:101`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T009 / CC.C10

Source symbol(s): `komorebi_math.coordinates.combinatorial.divisor_zeta_transform`. No attached provenance record under this label.

Locations: `coordinates/combinatorial.py:306`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

`H-C127`: status `Exactness.EXACT`; checked `('constant coefficients equal one', 'finite formal truncation')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T110 / GF-POLYNOMIAL-COBOUNDARY

Source symbol(s): `komorebi_math.generating.masks.PolynomialCoboundaryResult.certificate`. No attached provenance record under this label.

Locations: `generating/masks.py:907`. **Direct base sites:** `H-C133`.

`H-C133`: status `Exactness.EXACT`; checked `('finite degree bound', 'unit rational mask')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T111 / GF-RATIONAL-MASK-ALGEBRAIC

Source symbol(s): `komorebi_math.generating.masks.RationalMaskAlgebraicCertificate.certificate`. No attached provenance record under this label.

Locations: `generating/masks.py:772`. **Direct base sites:** `H-C131`.

`H-C131`: status `Exactness.EXACT`; checked `('prime characteristic', 'unit rational mask')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T112 / GF-SIGNAL-FIR-BRIDGE

Source symbol(s): `komorebi_math.generating.adapters.FIRSeriesAdapter.certificate`. No attached provenance record under this label.

Locations: `generating/adapters.py:61`. **Direct base sites:** `H-C116`.

`H-C116`: status `Exactness.NUMERICAL`; checked `('formal z is interpreted as one sample of delay',)`; unchecked `()`. Residual keys: `coefficient_to_tap`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T113 / INT.ADAPTER.DERIVATIVE

Source symbol(s): `komorebi_math.integration.adapters.AtomicIntegratedDerivativeProvider.certificate`. No attached provenance record under this label.

Locations: `integration/adapters.py:247`. **Direct base sites:** `H-C138`.

`H-C138`: status `self.exactness`; checked `('finite fixed weights', 'common provider source and target dimensions', 'linearity of finite differentiation')`; unchecked `('providers represent globally correct derivatives',)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T114 / INT.ADAPTER.FRAME

Source symbol(s): `komorebi_math.integration.adapters.analysis_synthesis_integration_certificate`. No attached provenance record under this label.

Locations: `integration/adapters.py:372`. **Direct base sites:** `H-C139`.

`H-C139`: status `_weakest_exactness(Exactness.NUMERICAL, system_certificate.exactness, measure_certificate.exactness)`; checked `_merged_strings(system_certificate.assumptions_checked, measure_certificate.assumptions_checked, ('analysis-synthesis system certificate incorporated', ...)`; unchecked `_merged_strings(system_certificate.assumptions_unchecked, measure_certificate.assumptions_unchecked)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T115 / INT.COORD.COVECTOR

Source symbol(s): `komorebi_math.integration.coordinates.PolynomialIntegrationCovector.certificate`. No attached provenance record under this label.

Locations: `integration/coordinates.py:183`, `integration/coordinates.py:202`. **Direct base sites:** `H-C140`, `H-C141`.

`H-C140`: status `status`; checked `('exact rational interval data', 'finite rational covector', 'coordinate dimension') + tuple(structure.assumptions_checked)`; unchecked `tuple(dict.fromkeys(unchecked))`. Residual keys: none recorded (computed/default when not literal). `H-C141`: status `Exactness.EXACT`; checked `('replayed exact graded polynomial basis witness', 'exact rational interval moments', 'finite coordinate truncation')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T116 / INT.COORD.FTC

Source symbol(s): `komorebi_math.integration.coordinates.coordinate_fundamental_theorem`. No attached provenance record under this label.

Locations: `integration/coordinates.py:297`. **Direct base sites:** `H-C142`.

`H-C142`: status `Exactness.EXACT`; checked `('exact derivative coordinate operator', 'exact integration covector', 'exact endpoint evaluation covectors')`; unchecked `()`. Residual keys: `coordinate_ftc`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T117 / INT.COORD.TRANSPORT

Source symbol(s): `komorebi_math.integration.coordinates.coordinate_transport_identity`. No attached provenance record under this label.

Locations: `integration/coordinates.py:340`. **Direct base sites:** `H-C143`.

`H-C143`: status `Exactness.EXACT`; checked `('exact polynomial connection transform', 'contragredient covector action', 'common physical interval measure')`; unchecked `()`. Residual keys: `covector_transport`.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T118 / INT.EVAL.ATOM

Source symbol(s): `komorebi_math.integration.quadrature._atomic_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:425`. **Direct base sites:** `H-C161`.

`H-C161`: status `Exactness.EXACT if exact else Exactness.NUMERICAL`; checked `('finite weighted sum over every atom', )`; unchecked `() if exact else ('floating-point roundoff is not enclosed',)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T119 / INT.EVAL.ATOM.MEASURE

Source symbol(s): `komorebi_math.integration.quadrature.integrate`. No attached provenance record under this label.

Locations: `integration/quadrature.py:1122`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T120 / INT.EVAL.ATOMIC.PRODUCT

Source symbol(s): `komorebi_math.integration.quadrature._product_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:863`. **Direct base sites:** `H-C166`.

`H-C166`: status `result_exactness`; checked `('one finite weighted sum over product support',) + tuple(measure_certificate.assumptions_checked)`; unchecked `unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T121 / INT.EVAL.ORIENTED.POLY

Source symbol(s): `komorebi_math.integration.quadrature.integrate_polynomial_oriented`. No attached provenance record under this label.

Locations: `integration/quadrature.py:1195`. **Direct base sites:** `H-C171`.

`H-C171`: status `Exactness.EXACT`; checked `('exact rational polynomial', 'oriented endpoint convention', 'nonnegative constant density')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T122 / INT.EVAL.POLY.MOMENTS

Source symbol(s): `komorebi_math.integration.quadrature._exact_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:1066`. **Direct base sites:** `H-C170`.

`H-C170`: status `exactness`; checked `('finite sparse polynomial', 'measure monomial moments') + checked`; unchecked `unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T123 / INT.EVAL.PUSHFORWARD.ATOMIC.CALLABLE

Source symbol(s): `komorebi_math.integration.quadrature.integrate`. No attached provenance record under this label.

Locations: `integration/quadrature.py:1142`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T124 / INT.EVAL.PUSHFORWARD.CALLABLE

Source symbol(s): `komorebi_math.integration.quadrature.integrate`. No attached provenance record under this label.

Locations: `integration/quadrature.py:1158`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T125 / INT.EVAL.ZERO.MEASURE

Source symbol(s): `komorebi_math.integration.quadrature._zero_interval_result`. No attached provenance record under this label.

Locations: `integration/quadrature.py:558`. **Direct base sites:** `H-C163`.

`H-C163`: status `Exactness.EXACT`; checked `('structurally zero finite measure',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T126 / INT.ID.COV.AFFINE

Source symbol(s): `komorebi_math.integration.identities.affine_interval_change_of_variables`. No attached provenance record under this label.

Locations: `integration/identities.py:314`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T127 / INT.ID.FTC

Source symbol(s): `komorebi_math.integration.identities.fundamental_theorem`. No attached provenance record under this label.

Locations: `integration/identities.py:87`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T128 / INT.ID.FUBINI

Source symbol(s): `komorebi_math.integration.identities.fubini_identity`. No attached provenance record under this label.

Locations: `integration/identities.py:214`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T129 / INT.ID.IBP

Source symbol(s): `komorebi_math.integration.identities.integration_by_parts`. No attached provenance record under this label.

Locations: `integration/identities.py:127`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T130 / INT.ID.PUSHFORWARD

Source symbol(s): `komorebi_math.integration.identities.pushforward_identity`. No attached provenance record under this label.

Locations: `integration/identities.py:272`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T131 / INT.MAP.1

Source symbol(s): `komorebi_math.integration.measures.ExactAffineMap.certificate`. No attached provenance record under this label.

Locations: `integration/measures.py:288`. **Direct base sites:** `H-C145`.

`H-C145`: status `Exactness.EXACT`; checked `('exact rational matrix', 'exact rational shift', 'rectangular affine typing')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T132 / INT.MEASURE.ATOM.1

Source symbol(s): `komorebi_math.integration.measures.AtomicMeasure.certificate`. No attached provenance record under this label.

Locations: `integration/measures.py:471`. **Direct base sites:** `H-C148`.

`H-C148`: status `self.exactness`; checked `('finite support', 'finite coordinates', 'nonnegative weights')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T133 / INT.MEASURE.ATOM.MASS

Source symbol(s): `komorebi_math.integration.measures.AtomicMeasure.mass`. No attached provenance record under this label.

Locations: `integration/measures.py:364`. **Direct base sites:** `H-C146`.

`H-C146`: status `self.exactness`; checked `('finite positive atomic weights',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T134 / INT.MEASURE.ATOM.MOMENT

Source symbol(s): `komorebi_math.integration.measures.AtomicMeasure.moment`. No attached provenance record under this label.

Locations: `integration/measures.py:410`. **Direct base sites:** `H-C147`.

`H-C147`: status `self.exactness`; checked `('finite atomic sum',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T135 / INT.MEASURE.INTERVAL.1

Source symbol(s): `komorebi_math.integration.measures.IntervalMeasure.certificate`. No attached provenance record under this label.

Locations: `integration/measures.py:678`. **Direct base sites:** `H-C151`.

`H-C151`: status `self.exactness`; checked `('ordered finite endpoints', 'constant nonnegative density')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T136 / INT.MEASURE.INTERVAL.MASS

Source symbol(s): `komorebi_math.integration.measures.IntervalMeasure.mass`. No attached provenance record under this label.

Locations: `integration/measures.py:549`. **Direct base sites:** `H-C149`.

`H-C149`: status `self.exactness`; checked `('bounded interval', 'constant nonnegative density')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T137 / INT.MEASURE.INTERVAL.MOMENT

Source symbol(s): `komorebi_math.integration.measures.IntervalMeasure.moment`. No attached provenance record under this label.

Locations: `integration/measures.py:585`. **Direct base sites:** `H-C150`.

`H-C150`: status `self.exactness`; checked `('closed-form monomial antiderivative',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T138 / INT.MEASURE.PRODUCT.1

Source symbol(s): `komorebi_math.integration.measures.ProductMeasure.certificate`. No attached provenance record under this label.

Locations: `integration/measures.py:829`. **Direct base sites:** `H-C154`.

`H-C154`: status `_aggregate_exactness((self.exactness, *(certificate.exactness for certificate in certificates)))`; checked `_unique_assumptions(('typed finite measure factors', 'finite Cartesian product'), *(certificate.assumptions_checked for certificate in certificates))`; unchecked `_unique_assumptions(*(certificate.assumptions_unchecked for certificate in certificates))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T139 / INT.MEASURE.PRODUCT.MASS

Source symbol(s): `komorebi_math.integration.measures.ProductMeasure.mass`. No attached provenance record under this label.

Locations: `integration/measures.py:742`. **Direct base sites:** `H-C152`.

`H-C152`: status `exactness`; checked `_unique_assumptions(('finite product mass',), *(certificate.assumptions_checked for certificate in certificates))`; unchecked `_unique_assumptions(*(certificate.assumptions_unchecked for certificate in certificates))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T140 / INT.MEASURE.PRODUCT.MOMENT

Source symbol(s): `komorebi_math.integration.measures.ProductMeasure.moment`. No attached provenance record under this label.

Locations: `integration/measures.py:794`. **Direct base sites:** `H-C153`.

`H-C153`: status `exactness`; checked `_unique_assumptions(('factorization of product-measure monomial moments',), *(certificate.assumptions_checked for certificate in certificates))`; unchecked `_unique_assumptions(*(certificate.assumptions_unchecked for certificate in certificates))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T141 / INT.MEASURE.PUSH.1

Source symbol(s): `komorebi_math.integration.measures.PushforwardMeasure.certificate`. No attached provenance record under this label.

Locations: `integration/measures.py:1024`. **Direct base sites:** `H-C157`.

`H-C157`: status `_aggregate_exactness((self.exactness, *(certificate.exactness for certificate in certificates)))`; checked `_unique_assumptions(('finite base measure', 'typed affine mapping' if exact_map else 'pushforward defined by precomposition'), *(certificate.assumptions...`; unchecked `_unique_assumptions(*(certificate.assumptions_unchecked for certificate in certificates), () if exact_map else _CALLA...`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T142 / INT.MEASURE.PUSH.MASS

Source symbol(s): `komorebi_math.integration.measures.PushforwardMeasure.mass`. No attached provenance record under this label.

Locations: `integration/measures.py:917`. **Direct base sites:** `H-C155`.

`H-C155`: status `_aggregate_exactness((self.exactness, *(certificate.exactness for certificate in certificates)))`; checked `_unique_assumptions(('pushforward preserves total mass',), *(certificate.assumptions_checked for certificate in certificates))`; unchecked `_unique_assumptions(*(certificate.assumptions_unchecked for certificate in certificates), () if exact_map else _CALLA...`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T143 / INT.MEASURE.PUSH.MOMENT

Source symbol(s): `komorebi_math.integration.measures.PushforwardMeasure.moment`. No attached provenance record under this label.

Locations: `integration/measures.py:991`. **Direct base sites:** `H-C156`.

`H-C156`: status `_aggregate_exactness((certificate.exactness for certificate in certificates))`; checked `_unique_assumptions(('pushforward moment equals the pulled-back monomial integral',), *(certificate.assumptions_checked for certificate in certificates))`; unchecked `_unique_assumptions(*(certificate.assumptions_unchecked for certificate in certificates))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T144 / INT.POLY.1

Source symbol(s): `komorebi_math.integration.polynomial.ExactPolynomial.certificate`. No attached provenance record under this label.

Locations: `integration/polynomial.py:344`. **Direct base sites:** `H-C158`.

`H-C158`: status `Exactness.EXACT`; checked `('positive ambient dimension', 'nonnegative integer exponents', 'exact rational coefficients', 'canonical sparse representation')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T145 / INT.PUSH.ATOMIC.SNAPSHOT.POLY

Source symbol(s): `komorebi_math.integration.quadrature._exact_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:937`. **Direct base sites:** `H-C168`.

`H-C168`: status `Exactness.CONDITIONAL if unchecked else result.certificate.exactness`; checked `result.certificate.assumptions_checked + ('callable pushforward support materialized once',)`; unchecked `result.certificate.assumptions_unchecked + unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T146 / INT.PUSH.ATOMIC.SNAPSHOT.POLY.MEASURE

Source symbol(s): `komorebi_math.integration.quadrature._exact_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:950`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T147 / INT.PUSH.POLY

Source symbol(s): `komorebi_math.integration.quadrature._exact_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:970`. **Direct base sites:** `H-C169`.

`H-C169`: status `base.certificate.exactness`; checked `base.certificate.assumptions_checked + ('pushforward integral equals pullback integral by definition',)`; unchecked `base.certificate.assumptions_unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T148 / INT.PUSH.POLY.MEASURE

Source symbol(s): `komorebi_math.integration.quadrature._exact_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:985`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T149 / INT.QUAD.BOUND.ASSUMED

Source symbol(s): `komorebi_math.integration.quadrature.DerivativeBound.assumed`. No attached provenance record under this label.

Locations: `integration/quadrature.py:205`. **Direct base sites:** `H-C159`.

`H-C159`: status `Exactness.CONDITIONAL`; checked `()`; unchecked `(description,)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T150 / INT.QUAD.POLY.BOUND

Source symbol(s): `komorebi_math.integration.quadrature.polynomial_derivative_bound`. No attached provenance record under this label.

Locations: `integration/quadrature.py:269`. **Direct base sites:** `H-C160`.

`H-C160`: status `Exactness.EXACT`; checked `('exact polynomial differentiation', 'coefficient triangle inequality', 'rational bounded interval') + tuple(structure.assumptions_checked)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T151 / INT.QUAD.RULE.1

Source symbol(s): `komorebi_math.integration.rules.QuadratureRule.certificate`. No attached provenance record under this label.

Locations: `integration/rules.py:492`. **Direct base sites:** `H-C176`.

`H-C176`: status `Exactness.EXACT if self.exact_data else Exactness.NUMERICAL`; checked `('finite nodes', 'finite signed weights', 'common node dimension', 'signed weights are not treated as a positive measure')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T152 / INT.QUAD.RULE.APPLY

Source symbol(s): `komorebi_math.integration.rules.QuadratureRule.apply`. No attached provenance record under this label.

Locations: `integration/rules.py:243`. **Direct base sites:** `H-C172`.

`H-C172`: status `Exactness.EXACT if exact_evaluation else Exactness.NUMERICAL`; checked `('finite quadrature functional evaluation', 'no target-integral equality inferred')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T153 / INT.QUAD.RULE.CERTIFIED.POLY

Source symbol(s): `komorebi_math.integration.rules.QuadratureRule.certify_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/rules.py:470`. **Direct base sites:** `H-C175`.

`H-C175`: status `Exactness.EXACT`; checked `('exact monomial moments through polynomial degree', 'linearity of finite quadrature functional')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T154 / INT.QUAD.RULE.DEGREE

Source symbol(s): `komorebi_math.integration.rules.QuadratureRule.degree_of_exactness`. No attached provenance record under this label.

Locations: `integration/rules.py:435`. **Direct base sites:** `H-C174`.

`H-C174`: status `certificate_exactness`; checked `('monomial moments compared consecutively from degree zero',) + tuple(measure_certificate.assumptions_checked)`; unchecked `() if exact_comparison else tuple(dict.fromkeys(inherited_unchecked)) + ('floating moment agreement implies exact alg...`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T155 / INT.QUAD.RULE.POLY

Source symbol(s): `komorebi_math.integration.rules.QuadratureRule.integrate_polynomial`. No attached provenance record under this label.

Locations: `integration/rules.py:311`. **Direct base sites:** `H-C173`.

`H-C173`: status `Exactness.EXACT if exact_evaluation else Exactness.NUMERICAL`; checked `('finite polynomial', 'finite quadrature moments', 'no target-integral equality inferred')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T156 / INT.QUAD.SIMPSON

Source symbol(s): `komorebi_math.integration.quadrature._simpson_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:646`. **Direct base sites:** `H-C164`.

`H-C164`: status `exactness`; checked `tuple(checked)`; unchecked `unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T157 / INT.QUAD.SIMPSON.EXACT.POLY

Source symbol(s): `komorebi_math.integration.quadrature._simpson_polynomial_integral`. No attached provenance record under this label.

Locations: `integration/quadrature.py:738`. **Direct base sites:** `H-C165`.

`H-C165`: status `exactness`; checked `checked`; unchecked `unchecked`. Residual keys: `richardson_difference`.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T158 / INT.QUAD.SIMPSON.EXACT.POLY.MEASURE

Source symbol(s): `komorebi_math.integration.quadrature.integrate`. No attached provenance record under this label.

Locations: `integration/quadrature.py:1112`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-005`, `EX-E-007`. **Literal test mentions:** none recorded.

Locations: `coordinates/frame_algebra.py:270`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T179 / KM-AS-GAUGE-TENSOR-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisGauge.tensor_product`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:283`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T180 / KM-AS-MAP-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:338`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T181 / KM-AS-MAP-ADD-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap.add`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:439`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T182 / KM-AS-MAP-ADJOINT-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap.adjoint`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:409`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T183 / KM-AS-MAP-COMPOSE-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap.then`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:393`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T184 / KM-AS-MAP-DUAL-ADJOINT-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap.dual_adjoint`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:417`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T185 / KM-AS-MAP-ID-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap.identity`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:358`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T186 / KM-AS-MAP-SCALE-01

Source symbol(s): `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap.scaled`. No attached provenance record under this label.

Locations: `coordinates/frame_algebra.py:428`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T187 / KM-B15-T01

Source symbol(s): `komorebi_math.refinement.polyphase.PolyphaseRefinement.certificate`. No attached provenance record under this label.

Locations: `refinement/polyphase.py:276`. **Direct base sites:** `H-C303`.

`H-C303`: status `exactness`; checked `('positive divisible packet orders', 'finite polyphase coordinate record', 'mixed-radix address law a = r + M s', 'coarsen after refine identity', 'nest...`; unchecked `()`. Residual keys: `coarsen_after_refine`, `direct_fine_analysis`.

Observed examples: `EX-E-003`, `EX-E-007`. **Literal test mentions:** none recorded.

H-T188 / KM-B15-T02

Source symbol(s): `komorebi_math.refinement.polyphase.PolyphaseRefinementTower.coherence_certificate`. No attached provenance record under this label.

Locations: `refinement/polyphase.py:626`. **Direct base sites:** `H-C304`.

`H-C304`: status `Exactness.EXACT if exact else Exactness.NUMERICAL`; checked `('nested divisible refinement tower', 'associativity of mixed-radix address composition')`; unchecked `()`. Residual keys: `sequential_vs_direct_refinement`.

Observed examples: `EX-E-003`. **Literal test mentions:** none recorded.

H-T189 / KM-B15-T03

Source symbol(s): `komorebi_math.refinement.polyphase.LatticePolyphaseRefinement.certificate`. No attached provenance record under this label.

Locations: `refinement/polyphase.py:857`. **Direct base sites:** `H-C305`.

`H-C305`: status `Exactness.EXACT if exact else Exactness.NUMERICAL`; checked `('componentwise divisible rectangular strides', 'finite rectangular lattice polyphase coordinates', 'componentwise address law a = r + M*s')`; unchecked `()`. Residual keys: `coarsen_after_refine`, `direct_fine_analysis`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T190 / KM-DOCS-017

Source symbol(s): `komorebi_math.release.documentation.check_stable_documentation`. No attached provenance record under this label.

Locations: `release/documentation.py:296`. **Direct base sites:** `H-C313`.

`H-C313`: status `Exactness.EXACT`; checked `('one documentation record per stable export', 'exact callable signatures and first-line summaries', 'no deprecated stable export')`; unchecked `('narrative completeness beyond the committed stable reference',)`. Residual keys: `missing`, `extra`, `changed`, `deprecated`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T191 / KM-DSP-C01

Declared claim: Finite lattice overlap-add certificate; `FINITE_CERTIFICATE`. Symbol: `komorebi_math.signals.windows.overlap_add_certificate`.

Declared hypotheses: uniform integer hop; infinite shift lattice away from finite boundaries. Suite label: `signals.windows`.

Locations: `signals/windows.py:213`, `signals/windows.py:243`. **Direct base sites:** `H-C361`.

`H-C361`: status `Exactness.NUMERICAL`; checked `('finite window', 'uniform integer hop')`; unchecked `('finite-record boundary coverage',)`. Residual keys: `overlap_spread`, `minimum_overlap`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T192 / KM-DSP-C02

Source symbol(s): `komorebi_math.signals.filtering.FIRFilter.certificate`. No attached provenance record under this label.

Locations: `signals/filtering.py:181`. **Direct base sites:** `H-C336`.

`H-C336`: status `Exactness.NUMERICAL`; checked `('finite real linear-phase design', 'declared gain normalization')`; unchecked `()`. Residual keys: `tap_symmetry`, `reference_gain`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T193 / KM-DSP-C03

Source symbol(s): `komorebi_math.signals.denoise.denoising_risk_certificate`. No attached provenance record under this label.

Locations: `signals/denoise.py:349`. **Direct base sites:** `H-C328`.

`H-C328`: status `Exactness.NUMERICAL`; checked `('supplied clean finite reference',)`; unchecked `()`. Residual keys: `noisy_mse`, `denoised_mse`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T194 / KM-DSP-C04

Source symbol(s): `komorebi_math.signals.recursive.LinearFilter.stability_certificate`. No attached provenance record under this label.

Locations: `signals/recursive.py:160`. **Direct base sites:** `H-C345`.

`H-C345`: status `Exactness.NUMERICAL`; checked `('finite rational transfer function',)`; unchecked `()`. Residual keys: `maximum_pole_radius`, `stability_margin`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T195 / KM-DSP-D01

Declared claim: Finite deterministic analysis window; `CLASSICAL`. Symbol: `komorebi_math.signals.windows.get_window`.

Declared hypotheses: positive finite window length. Suite label: `signals.windows`.

Locations: `signals/windows.py:48`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T196 / KM-DSP-D02

Declared claim: Finite uniform signal framing; `DEFINITION`. Symbol: `komorebi_math.signals.time_frequency.frame_signal`.

Declared hypotheses: finite one dimensional signal; positive frame and hop lengths. Suite label: `signals.time_frequency`.

Locations: `signals/time_frequency.py:83`, `signals/time_frequency.py:94`. **Direct base sites:** `H-C356`.

`H-C356`: status `Exactness.EXACT`; checked `('complete equal-length frames', 'uniform integer hop')`; unchecked `()`. Residual keys: `uncovered_tail`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T197 / KM-DSP-D03

Declared claim: Finite short-time Fourier transform; `CLASSICAL`. Symbol: `komorebi_math.signals.time_frequency.stft`.

Declared hypotheses: uniform finite framing; declared window and Fourier length. Suite label: `signals.time_frequency`.

Locations: `signals/time_frequency.py:247`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T198 / KM-DSP-D04

Declared claim: Finite spectrogram scaling; `CLASSICAL`. Symbol: `komorebi_math.signals.time_frequency.spectrogram`.

Declared hypotheses: finite STFT; declared spectral scaling. Suite label: `signals.time_frequency`.

Locations: `signals/time_frequency.py:432`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T199 / KM-DSP-D05

Declared claim: Finite FIR frequency response; `CLASSICAL`. Symbol: `komorebi_math.signals.filtering.fir_frequency_response`.

Declared hypotheses: finite impulse response; positive sample rate. Suite label: `signals.filtering`.

Declared claim: Finite modified periodogram; `CLASSICAL`. Symbol: `komorebi_math.signals.spectral.periodogram`.

Declared hypotheses: finite signal; declared window and scaling. Suite label: `signals.spectral`.

Locations: `signals/filtering.py:95`, `signals/spectral.py:157`, `signals/spectral.py:192`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T200 / KM-DSP-D06

Declared claim: Windowed-sinc finite FIR design; `CLASSICAL`. Symbol: `komorebi_math.signals.filtering.design_fir`.

Declared hypotheses: cutoffs strictly inside Nyquist; finite tap count. Suite label: `signals.filtering`.

Declared claim: Finite Welch power spectral estimate; `CLASSICAL`. Symbol: `komorebi_math.signals.spectral.welch_psd`.

Declared hypotheses: complete uniform finite segments; declared averaging rule. Suite label: `signals.spectral`.

Locations: `signals/filtering.py:207`, `signals/spectral.py:237`, `signals/spectral.py:279`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T201 / KM-DSP-D07

Declared claim: Finite Welch cross spectrum and magnitude-squared coherence; `CLASSICAL`. Symbol: `komorebi_math.signals.spectral.cross_spectrum`.

Declared hypotheses: paired finite segments; nonzero auto spectra for interpreted transfer bins. Suite label: `signals.spectral`.

Locations: `signals/spectral.py:297`, `signals/spectral.py:369`. **Direct base sites:** `H-C353`.

`H-C353`: status `Exactness.NUMERICAL`; checked `('paired complete frames', 'finite DFT scaling')`; unchecked `('linear time-invariant data-generating model', 'statistical consistency')`. Residual keys: `coherence_bound`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T202 / KM-DSP-D10

Declared claim: Finite Haar coefficient shrinkage; `CLASSICAL`. Symbol: `komorebi_math.signals.denoise.wavelet_denoise`.

Declared hypotheses: finite dyadic Haar decomposition; declared threshold rule. **Declared limits:** noise-model optimality is not inferred from one finite signal. Suite label: `signals.denoise`.

Locations: `signals/denoise.py:241`, `signals/denoise.py:299`. **Direct base sites:** `H-C327`.

`H-C327`: status `Exactness.NUMERICAL`; checked `('finite threshold recurrence', 'complete Haar synthesis')`; unchecked `('Gaussian white-noise interpretation' if sigma is None else 'declared noise scale matches the application', 'thresho...`. Residual keys: `shrinkage_monotonicity`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T203 / KM-DSP-D11

Declared claim: Windowed finite rational-resampling anti-alias filter; `CLASSICAL`. Symbol: `komorebi_math.signals.resampling.design_resample_filter`.

Declared hypotheses: positive reduced rational rate; odd finite tap count. **Declared limits:** zero-extension boundary convention; finite-window approximation. Suite label: `signals.resampling`.

Locations: `signals/resampling.py:71`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T204 / KM-DSP-D12

Declared claim: Finite least-mean-squares adaptation; `CLASSICAL`. Symbol: `komorebi_math.signals.adaptive.lms_filter`.

Declared hypotheses: finite paired signals; positive step size. **Declared limits:** the finite routine does not assert stochastic convergence. Suite label: `signals.adaptive`.

Locations: `signals/adaptive.py:99`, `signals/adaptive.py:121`. **Direct base sites:** `H-C323`.

`H-C323`: status `Exactness.NUMERICAL`; checked `('finite recursion', 'declared parameter ranges')`; unchecked `('persistent excitation', 'stochastic independence assumptions', 'convergence for the supplied step or forgetting fac...`. Residual keys: `nonfinite_entries`.

Observed examples: `EX-E-040`. **Literal test mentions:** none recorded.

H-T205 / KM-DSP-D13

Declared claim: Finite normalized least-mean-squares adaptation; `CLASSICAL`. Symbol: `komorebi_math.signals.adaptive.nlms_filter`.

Declared hypotheses: finite paired signals; positive normalization floor. **Declared limits:** the finite routine does not assert stochastic convergence. Suite label: `signals.adaptive`.

Locations: `signals/adaptive.py:174`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T206 / KM-DSP-D14

Declared claim: Finite recursive least-squares adaptation; `CLASSICAL`. Symbol: `komorebi_math.signals.adaptive.rls_filter`.

Declared hypotheses: finite paired signals; positive inverse-covariance initialization; forgetting factor in (0, 1]. **Declared limits:** the finite routine does not assert a stochastic identification theorem. Suite label: `signals.adaptive`.

Locations: `signals/adaptive.py:237`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T207 / KM-DSP-D26

Declared claim: Direct-form II transposed finite recursion; `CLASSICAL`. Symbol: `komorebi_math.signals.recursive.lfilter`.

Declared hypotheses: finite normalized transfer coefficients. Suite label: `signals.recursive`.

Locations: `signals/recursive.py:172`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T208 / KM-DSP-D27

Declared claim: Normalized audio-EQ biquad construction; `CLASSICAL`. Symbol: `komorebi_math.signals.recursive.design_biquad`.

Declared hypotheses: frequency strictly inside Nyquist; positive Q. Suite label: `signals.recursive`.

Locations: `signals/recursive.py:194`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T209 / KM-DSP-D28

Declared claim: Zero-padded finite FFT convolution; `CLASSICAL`. Symbol: `komorebi_math.signals.fft_convolution.fft_convolve`.

Declared hypotheses: finite one-dimensional inputs; zero padding to linear-convolution length. Suite label: `signals.fft_convolution`.

Locations: `signals/fft_convolution.py:48`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T210 / KM-DSP-T01

Declared claim: Finite window gain and equivalent noise bandwidth; `CLASSICAL`. Symbol: `komorebi_math.signals.windows.window_metrics`.

Declared hypotheses: finite nonzero coherent gain; positive sample rate. Suite label: `signals.windows`.

Locations: `signals/windows.py:155`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T211 / KM-DSP-T02

Declared claim: Canonical finite lattice dual window; `PROVED`. Symbol: `komorebi_math.signals.windows.canonical_dual_window`.

Declared hypotheses: nonzero squared overlap profile; uniform integer hop. Suite label: `signals.windows`.

Locations: `signals/windows.py:262`, `signals/windows.py:295`. **Direct base sites:** `H-C362`.

`H-C362`: status `Exactness.NUMERICAL`; checked `('uniform integer hop',)`; unchecked `('finite-record boundary coverage',)`. Residual keys: `dual_overlap`, `minimum_squared_overlap`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T212 / KM-DSP-T03

Declared claim: Normalized finite STFT overlap-add reconstruction; `PROVED`. Symbol: `komorebi_math.signals.time_frequency.istft`.

Declared hypotheses: no destructive detrending; nonzero finite overlap denominator. Suite label: `signals.time_frequency`.

Locations: `signals/time_frequency.py:235`, `signals/time_frequency.py:327`, `signals/time_frequency.py:390`. **Direct base sites:** `H-C357`, `H-C358`.

H-C357: status Exactness.NUMERICAL; checked ('matching finite source', 'normalized overlap-add'); unchecked (). Residual keys: stft_roundtrip. H-C358: status Exactness.NUMERICAL; checked ('finite Fourier inversion', 'finite overlap normalization'); unchecked ('source agreement requires a separate roundtrip comparison',). Residual keys: normalized_overlap_identity, minimum_overlap.

Observed examples: EX-E-040. **Literal test mentions:** none recorded.

H-T213 / KM-DSP-T04

Declared claim: Finite discrete Parseval identity; PROVED. Symbol: komorebi_math.signals.spectral.parseval_certificate.

Declared hypotheses: NumPy DFT normalization convention; finite one dimensional signal. Suite label: signals.spectral.

Locations: signals/spectral.py:397, signals/spectral.py:418. **Direct base sites:** H-C354.

H-C354: status Exactness.NUMERICAL; checked ('finite DFT pair',); unchecked (). Residual keys: parseval.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T214 / KM-DSP-T05

Declared claim: Chunk-invariant finite FIR execution; PROVED. Symbol: komorebi_math.signals.filtering.stream_fir_filter.

Declared hypotheses: ordered nonoverlapping chunks; common FIR taps. Suite label: signals.filtering.

Locations: signals/filtering.py:390, signals/filtering.py:425. **Direct base sites:** H-C337.

H-C337: status Exactness.NUMERICAL; checked ('ordered complete chunk partition', 'finite causal FIR'); unchecked (). Residual keys: streaming_batch_equivalence.

Observed examples: EX-E-040. **Literal test mentions:** none recorded.

H-T215 / KM-DSP-T06

Declared claim: Finite multilevel Haar reconstruction; PROVED. Symbol: komorebi_math.signals.denoise.haar_decompose.

Declared hypotheses: signal length divisible by the requested dyadic depth. Suite label: signals.denoise.

Declared claim: Finite centered polyphase rational-resampling identity; PROVED. Symbol: komorebi_math.signals.resampling.resample_poly_result.

Declared hypotheses: zero-extension boundary convention; odd centered FIR kernel. Suite label: signals.resampling.

Locations: signals/denoise.py:178, signals/denoise.py:190, signals/resampling.py:186, signals/resampling.py:215. **Direct base sites:** H-C326, H-C347.

H-C326: status Exactness.NUMERICAL; checked ('complete finite Haar decomposition',); unchecked (). Residual keys: haar_reconstruction, haar_energy. H-C347: status Exactness.NUMERICAL; checked ('centered zero-extension convention', 'reduced rational rate'); unchecked ('application-specific alias rejection', 'boundary-transient acceptability'). Residual keys: polyphase_reference, dc_gain.

Observed examples: EX-E-040. **Literal test mentions:** none recorded.

H-T216 / KM-DSP-T07

Declared claim: Chunk-invariant finite STFT framing; PROVED. Symbol: komorebi_math.signals.streaming.stream_stft.

Declared hypotheses: contiguous complete chunk partition; zero-padded terminal framing. Suite label: signals.streaming.

Locations: signals/streaming.py:263, signals/streaming.py:330. **Direct base sites:** H-C355.

H-C355: status Exactness.NUMERICAL; checked ('contiguous declared chunks', 'matching finite STFT parameters'); unchecked (). Residual keys: stream_batch_coefficients, stream_batch_times.

Observed examples: EX-E-040. **Literal test mentions:** none recorded.

H-T217 / KM-DSP-T09

Source symbol(s): komorebi_math.signals.recursive.stream_lfilter. No attached provenance record under this label.

Locations: signals/recursive.py:292. **Direct base sites:** H-C346.

H-C346: status Exactness.NUMERICAL; checked ('zero initial state', 'ordered contiguous chunks'); unchecked (). Residual keys: streaming_batch_max_abs.

Observed examples: EX-E-040. **Literal test mentions:** none recorded.

H-T218 / KM-DSP-T10

Declared claim: Finite overlap-add convolution identity; PROVED. Symbol: komorebi_math.signals.fft_convolution.overlap_add_convolve.

Declared hypotheses: ordered contiguous chunks; zero-padded FFT blocks. Suite label: signals.fft_convolution.

Locations: signals/fft_convolution.py:192, signals/fft_convolution.py:236. **Direct base sites:** H-C331.

H-C331: status Exactness.NUMERICAL; checked ('finite ordered input', 'linear zero-padded convolution'); unchecked (). Residual keys: overlap_add_direct_max_abs.

Observed examples: EX-E-040. **Literal test mentions:** none recorded.

H-T219 / KM-EVIDENCE-017

Source symbol(s): komorebi_math.release.evidence.check_validation_evidence. No attached provenance record under this label.

Locations: release/evidence.py:286. **Direct base sites:** H-C314.

H-C314: status Exactness.EXACT; checked ('current-version execution exists', 'required platform families are covered', 'inherited evidence is authorized by the upgrade contract', 'evidence sou...; unchecked () if require_current_all_platforms else ('release candidate requires current-version evidence on every platform fami.... Residual keys: missing_platforms, missing_current_platforms, invalid_records, invalid_sources.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T220 / KM-FINITE-GROUP

Source symbol(s): komorebi_math.langlands.finite_image.groups.FiniteGroup.certificate. No attached provenance record under this label.

Locations: langlands/finite_image/groups.py:158. **Direct base sites:** H-C182.

H-C182: status Exactness.EXACT; checked ('finite explicit group table',); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T221 / KM-GOLDEN-011

Source symbol(s): komorebi_math.golden._exact_snapshot, komorebi_math.golden._result, komorebi_math.golden.run_behavioral_golden_fixture. No attached provenance record under this label.

Locations: golden.py:104, golden.py:228, golden.py:590. **Direct base sites:** H-C135, H-C136, H-C137.

H-C135: status Exactness.EXACT; checked ('committed finite golden coefficient table',); unchecked (). Residual keys: none recorded (computed/default when not literal). H-C136: status exactness; checked ('closed built-in golden case evaluator', 'committed explicit inputs and expected output'); unchecked (). Residual keys: golden_residual. H-C137: status Exactness.EXACT; checked ('fixture schema and digest', 'closed case-kind registry', 'deterministic committed expected values'); unchecked ('the fixture set is representative rather than exhaustive',). Residual keys: failed_cases.

Observed examples: EX-E-002. **Literal test mentions:** none recorded.

H-T222 / KM-GPU-016

Source symbol(s): `komorebi_math.release.gpu.qualify_gpu`. No attached provenance record under this label.

Locations: `release/gpu.py:152`. **Direct base sites:** `H-C315`.

`H-C315`: status `Exactness.NUMERICAL`; checked `tuple((f'isolated {name} CUDA execution' for name in passed_required))`; unchecked `tuple((f'{result.backend} was optional for this invocation' for result in results if not required[result.backend]))`. Residual keys: `failed_required_backends`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T223 / KM-INDUCED-REPRESENTATION

Source symbol(s): `komorebi_math.langlands.finite_image.characters.InducedRepresentation.certificate`. No attached provenance record under this label.

Locations: `langlands/finite_image/characters.py:104`. **Direct base sites:** `H-C179`.

`H-C179`: status `Exactness.NUMERICAL`; checked `('finite explicit group', 'multiplicative inducing character')`; unchecked `()`. Residual keys: `representation_law`.

Observed examples: `EX-E-020`. **Literal test mentions:** none recorded.

H-T224 / KM-PERSIST-016

Source symbol(s): `komorebi_math.persistence_contract.compare_portable_codec_contract`. No attached provenance record under this label.

Locations: `persistence_contract.py:268`. **Direct base sites:** `H-C273`.

`H-C273`: status `Exactness.EXACT`; checked `('package-owned portable codec tags', 'codec implementation type identity', 'monotone codec versions', 'adjacent migration path for each version increase')`; unchecked `('semantic equivalence of extension-owned codecs', 'compatibility of undocumented serialized implementation details')`. Residual keys: `removed_tags`, `type_changes`, `version_decreases`, `missing_migrations`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T225 / KM-READINESS-017

Source symbol(s): `komorebi_math.release.readiness.check_beta_readiness`. No attached provenance record under this label.

Locations: `release/readiness.py:42`. **Direct base sites:** `H-C316`.

`H-C316`: status `Exactness.EXACT`; checked `tuple((x.name for x in checks if x.passed))`; unchecked `tuple(unchecked)`. Residual keys: `failed_checks`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T226 / KM-REL-16

Source symbol(s): `komorebi_math.qualification.ReleaseQualificationReport.certificate`. No attached provenance record under this label.

Locations: `qualification.py:308`. **Direct base sites:** `H-C274`.

`H-C274`: status `Exactness.NUMERICAL`; checked `tuple((check.name for check in self.verification.checks if check.passed))`; unchecked `() if self.gpu is not None else ('hardware-backed CUDA qualification not requested',)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T227 / KM-RELEASE-CONTRACT-021

Source symbol(s): `komorebi_math.release.contract.check_release_contract`. No attached provenance record under this label.

Locations: `release/contract.py:91`. **Direct base sites:** `H-C312`.

`H-C312`: status `Exactness.EXACT`; checked `tuple((x.name for x in checks if x.passed))`; unchecked `('current-version execution on all platforms is enforced by RC readiness', 'hardware performance is not semantic comp...`. Residual keys: `failed_checks`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T228 / KM-STABLE-CONTRACT-016

Source symbol(s): `komorebi_math.stable_contract.check_stable_contract`. No attached provenance record under this label.

Locations: `stable_contract.py:53`. **Direct base sites:** `H-C363`.

`H-C363`: status `Exactness.EXACT`; checked `('stable exports and signatures', 'committed stable mathematical behavior', 'portable codec identity and migration paths')`; unchecked `('performance stability across hardware', 'compatibility of research and experimental namespaces')`. Residual keys: `api_failures`, `semantic_failures`, `persistence_failures`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T229 / KM-STABLE-SEM-016

Source symbol(s): `komorebi_math.stable_semantics.run_stable_semantics_fixture`. No attached provenance record under this label.

Locations: `stable_semantics.py:415`. **Direct base sites:** `H-C364`.

`H-C364`: status `Exactness.EXACT`; checked `('fixture schema and canonical digest', 'closed stable semantic case registry', 'exact committed expected values', 'major stable API families represented')`; unchecked `('fixture coverage is representative rather than exhaustive', 'optional hardware backend equivalence')`. Residual keys: `failed_cases`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T230 / KM-UPGRADE-017

Source symbol(s): `komorebi_math.release.upgrade.check_upgrade_contract`. No attached provenance record under this label.

Locations: `release/upgrade.py:134`. **Direct base sites:** `H-C317`.

`H-C317`: status `Exactness.EXACT`; checked `('stable API predecessor manifests', 'closed stable semantics', 'portable codec continuity', 'digest-checked predecessor records')`; unchecked `('undocumented implementation objects', 'pickle payloads', 'third-party codecs')`. Residual keys: `failed_checks`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T231 / NGF.BELL_DIGIT_SUM_REDUCTION

Source symbol(s): `komorebi_math.generating.bell.BellDigitReduction.certificate`. No attached provenance record under this label.

Locations: `generating/bell.py:187`. **Direct base sites:** `H-C120`.

`H-C120`: status `Exactness.EXACT`; checked `('prime modulus', 'factorial_power >= 2', 'prime-1 divides factorial_power-1')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T232 / NGF.BELL_RESIDUE_AUTOMATON

Source symbol(s): `komorebi_math.generating.bell.BellResidueAutomaton.certificate`. No attached provenance record under this label.

Locations: `generating/bell.py:380`. **Direct base sites:** `H-C121`.

`H-C121`: status `Exactness.EXACT`; checked `('prime modulus', 'factorial_power >= 2', 'prime-1 divides factorial_power-1')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T233 / NGF.FINITE_NORMALIZED_SERIES

Source symbol(s): `komorebi_math.generating.finite_series.FiniteNormalizedSeries.certificate`. No attached provenance record under this label.

Locations: `generating/finite_series.py:423`. **Direct base sites:** `H-C126`.

`H-C126`: status `Exactness.EXACT`; checked `('finite degree', 'explicit coefficient domain')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-010`. **Literal test mentions:** none recorded.

H-T234 / NGF.POINTED_SUBINDEX

Source symbol(s): `komorebi_math.generating.bell.PointedSubindexCertificate.certificate`. No attached provenance record under this label.

Locations: `generating/bell.py:132`. **Direct base sites:** `H-C118`.

`H-C118`: status `Exactness.EXACT`; checked `('prime modulus', 'positive index')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T235 / NGF.UNIVERSAL_PRODUCT_AND_TRANSFER

Source symbol(s): `komorebi_math.generating.finite_series.SeriesTransferCertificate.certificate`. No attached provenance record under this label.

Locations: `generating/finite_series.py:77`. **Direct base sites:** `H-C123`.

`H-C123`: status `Exactness.EXACT`; checked `('finite truncation', 'exact coefficient domain')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T236 / PSC-I-D01

Declared claim: Typed operator grammar; `DEFINITION`; Paper I. Symbol: `komorebi_math.core.grammar.OperatorGrammar`.

Declared hypotheses: finite vertex set; typed arrows. **Declared limits:** relations are finite linear combinations of typed paths. Suite label: `core.grammar`.

Locations: `core/grammar.py:66`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T237 / PSC-I-D05

Declared claim: Realized operator algebra; DEFINITION; Paper I. Symbol: komorebi_math.core.algebra.OperatorAlgebra.

Declared hypotheses: finite matrix generators. Suite label: core.algebra.

Locations: core/algebra.py:30, core/algebra.py:138. **Direct base sites:** H-C065.

H-C065: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('generator dimensions', 'linear independence', 'multiplicative closure'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T238 / PSC-I-T01

Declared claim: Typed realization and quotient path algebra correspondence; PROVED; Paper I. Symbol: komorebi_math.core.realization.OperatorRealization.

Declared hypotheses: finite dimensional matrix realization. Suite label: core.realization.

Locations: core/realization.py:24, core/realization.py:109. **Direct base sites:** H-C073.

H-C073: status exactness; checked ('operator shapes', 'typed path composition', 'declared relations'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-057. **Literal test mentions:** none recorded.

H-T239 / PSC-I-T02

Declared claim: Finite seed hull generation; PROVED; Paper I. Symbol: komorebi_math.core.seeds.SeedSystem.

Declared hypotheses: finite dimensional realized operator family. **Declared limits:** numerical rank depends on the declared tolerance. Suite label: core.seeds.

Locations: core/seeds.py:43, core/seeds.py:147. **Direct base sites:** H-C074.

H-C074: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('operator dimensions', 'seed dimensions', 'finite orbit closure'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-043. **Literal test mentions:** none recorded.

H-T240 / PSC-I-T10

Declared claim: Semisimple seed rank formula; PROVED; Paper I. Symbol: komorebi_math.core.seeds.semisimple_seed_rank.

Declared hypotheses: semisimple Artinian acting algebra. Suite label: core.seed_rank.

Locations: core/seeds.py:269. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T241 / PSC-I-T13

Declared claim: Single operator primary seed rank formula; PROVED; Paper I. Symbol: komorebi_math.core.seeds.single_operator_seed_rank.

Declared hypotheses: exact matrix over the rational field. **Declared limits:** the current executable factorization path is implemented over rational entries. Suite label: core.seed_rank.

Locations: core/seeds.py:311. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T242 / PSC-I-T20

Declared claim: Exact finite packet coordinates; `PROVED`; Paper I. Symbol: `komorebi_math.core.packets.PacketSystem`.

Declared hypotheses: finite complete family of pairwise annihilating idempotents. Suite label: `core.packets`.

Locations: `core/packets.py:42`, `core/packets.py:119`, `core/packets.py:144`. **Direct base sites:** `H-C071`, `H-C072`.

`H-C071`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('common dimension', 'idempotence', 'annihilation', 'completeness')`; unchecked `()`. Residual keys: `idempotence`, `annihilation`, `completeness`. `H-C072`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('packet system axioms',)`; unchecked `()`. Residual keys: `self_adjointness`.

Observed examples: `EX-E-002`, `EX-E-015`, `EX-E-031`, `EX-E-037`, `EX-E-042`, `EX-E-043`, `EX-E-047`, `EX-E-048`, `EX-E-049`, `EX-E-050`. **Literal test mentions:** `test_certificates_registry.py`, `test_unified_extensions_cli.py`.

H-T243 / PSC-I-T27

Declared claim: Transfer block algebra; `PROVED`; Paper I. Symbol: `komorebi_math.core.operators.PacketOperator`.

Declared hypotheses: finite source and target packet systems. Suite label: `core.operators`.

Locations: `core/operators.py:15`, `core/operators.py:93`. **Direct base sites:** `H-C070`.

`H-C070`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('source packet axioms', 'target packet axioms', 'block shapes')`; unchecked `()`. Residual keys: `block_reprojection`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T244 / PSC-I-T29

Source symbol(s): `komorebi_math.core.transfer.block_from_paths`. No attached provenance record under this label.

Locations: `core/transfer.py:76`. **Direct base sites:** `H-C076`.

`H-C076`: status `Exactness.EXACT if operator.backend.exact else Exactness.NUMERICAL`; checked `('packet endomorphism', 'fixed path length')`; unchecked `()`. Residual keys: `path_sum`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T245 / PSC-I-T40

Declared claim: Packet transfer graph; `DEFINITION`; Paper I. Symbol: `komorebi_math.core.graphs.TransferGraph`.

Declared hypotheses: none listed. Suite label: `core.graphs`.

Locations: `core/graphs.py:15`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T246 / PSC-I-T44

Source symbol(s): `komorebi_math.core.graphs.TransferGraph.source_component_certificate`. No attached provenance record under this label.

Locations: `core/graphs.py:195`. **Direct base sites:** `H-C066`.

`H-C066`: status `Exactness.CONDITIONAL`; checked `('finite transfer graph', 'source strongly connected components')`; unchecked `('edge maps are surjective on the declared packet spaces', 'each source component is generated by one packet pure seed')`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T247 / PSC-I-T50

Declared claim: Naturality of seed hulls and packet blocks; `PROVED`; Paper I. Symbol: `komorebi_math.core.morphisms.OperatorMorphism`.

Declared hypotheses: declared intertwining equations. Suite label: `core.morphisms`.

Locations: `core/morphisms.py:17`, `core/morphisms.py:72`, `core/morphisms.py:173`. **Direct base sites:** `H-C067`, `H-C069`.

`H-C067`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('operator dimensions', 'declared operator map')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal). `H-C069`: status `Exactness.EXACT if backend.exact else Exactness.NUMERICAL`; checked `('operator intertwining', 'declared seed images')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T248 / PSC-I-T52

Source symbol(s): `komorebi_math.core.morphisms.PacketMorphism.certificate`. No attached provenance record under this label.

Locations: `core/morphisms.py:122`. **Direct base sites:** `H-C068`.

`H-C068`: status `Exactness.EXACT if backend.exact else Exactness.NUMERICAL`; checked `('source packets', 'target packets', 'declared aggregation map')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T249 / PSC-II-C09

Declared claim: Finite coprime residue factorization; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.crt.crt_many`.

Declared hypotheses: pairwise coprime positive moduli. Suite label: `refinement.crt`.

Locations: `refinement/crt.py:67`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T250 / PSC-II-C11

Source symbol(s): `komorebi_math.refinement.weighted.WeightedTransferGraph.exact_inverse_if_acyclic`. No attached provenance record under this label.

Locations: `refinement/weighted.py:341`. **Direct base sites:** `H-C311`.

`H-C311`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('acyclic transfer graph', 'invertible packet diagonal')`; unchecked `()`. Residual keys: `inverse_residual`.

Observed examples: `EX-E-047`. **Literal test mentions:** none recorded.

H-T251 / PSC-II-C21

Source symbol(s): `komorebi_math.refinement.defects.LinearRefinementDefect.polynomial`. No attached provenance record under this label.

Locations: `refinement/defects.py:122`. **Direct base sites:** `H-C296`.

`H-C296`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('finite polynomial',)`; unchecked `()`. Residual keys: `polynomial_identity`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T252 / PSC-II-D02

Declared claim: Packet refinement; `DEFINITION`; Paper II. Symbol: `komorebi_math.refinement.towers.PacketRefinement`.

Declared hypotheses: finite packet systems on one ambient space. Suite label: `refinement.towers`.

Locations: `refinement/towers.py:16`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T253 / PSC-II-D05

Declared claim: Residue packet system; `DEFINITION`; Paper II. Symbol: `komorebi_math.refinement.residue.residue_packet_system`.

Declared hypotheses: finite coordinate length; positive modulus. Suite label: `refinement.residue`.

Locations: `refinement/residue.py:17`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T254 / PSC-II-D12

Declared claim: Lattice packet data; `DEFINITION`; Paper II. Symbol: `komorebi_math.refinement.lattices.LatticePacketData`.

Declared hypotheses: rational packet projectors; full lattice basis. Suite label: `refinement.lattices`.

Locations: `refinement/lattices.py:77`, `refinement/lattices.py:140`. **Direct base sites:** `H-C300`.

`H-C300`: status `Exactness.EXACT`; checked `('rational packet axioms', 'full lattice basis') + (('integral split inclusion',) if self.split_basis is not None else ())`; unchecked `()`. Residual keys: `packet_axioms`.

Observed examples: `EX-E-016`. **Literal test mentions:** none recorded.

H-T255 / PSC-II-D19

Declared claim: Linear refinement defect; `DEFINITION`; Paper II. Symbol: `komorebi_math.refinement.defects.LinearRefinementDefect`.

Declared hypotheses: linear fine and coarse operators; linear coarsening map. Suite label: `refinement.defects`.

Locations: `refinement/defects.py:25`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T256 / PSC-II-SNF

Declared claim: Smith normal form over the integers; `CLASSICAL`; Paper II. Symbol: `komorebi_math.refinement.smith.smith_decomposition`.

Declared hypotheses: integer matrix. Suite label: `refinement.smith`.

Locations: `refinement/smith.py:67`, `refinement/smith.py:78`. **Direct base sites:** `H-C306`.

`H-C306`: status `Exactness.EXACT`; checked `('integer matrix', 'unimodular transforms', 'diagonal divisibility')`; unchecked `()`. Residual keys: `smith_identity`.

Observed examples: `EX-E-016`. **Literal test mentions:** none recorded.

H-T257 / PSC-II-T03

Source symbol(s): `komorebi_math.refinement.towers.PacketRefinement.certificate`. No attached provenance record under this label.

Locations: `refinement/towers.py:72`. **Direct base sites:** `H-C308`.

`H-C308`: status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; checked `('packet axioms', 'one parent per fine packet', 'coarse projector equals child sum')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-047`. **Literal test mentions:** none recorded.

H-T258 / PSC-II-T04

Declared claim: Exact coordinate change across one refinement; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.towers.PacketRefinement.coarsen`.

Declared hypotheses: exact packet refinement. Suite label: `refinement.towers`.

Locations: `refinement/towers.py:83`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T259 / PSC-II-T05

Declared claim: Coherence of finite refinement towers; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.towers.RefinementTower`.

Declared hypotheses: adjacent exact packet refinements. Suite label: `refinement.towers`.

Locations: `refinement/towers.py:143`, `refinement/towers.py:201`. **Direct base sites:** `H-C309`.

`H-C309`: status `Exactness.EXACT if all((certificate.exactness is Exactness.EXACT for certificate in certificates)) els...`; checked `('all adjacent refinements', 'level coherence')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T260 / PSC-II-T06

Declared claim: Exact residue analysis and synthesis; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.residue.residue_analyze`.

Declared hypotheses: finite sequence; positive modulus. Suite label: `refinement.residue`.

Locations: `refinement/residue.py:106`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T261 / PSC-II-T07

Declared claim: Nested residue refinement; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.residue.nested_residue_address`.

Declared hypotheses: positive outer and inner moduli. Suite label: `refinement.residue`.

Locations: `refinement/residue.py:142`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T262 / PSC-II-T08

Declared claim: Coprime factorization of residue addresses; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.crt.crt_pair`.

Declared hypotheses: pairwise coprime positive moduli. Suite label: `refinement.crt`.

Locations: `refinement/crt.py:37`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T263 / PSC-II-T10

Declared claim: Weighted inverse expansion; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.weighted.WeightedTransferGraph`.

Declared hypotheses: invertible packet diagonal; positive declared transfer weights. Suite label: `refinement.weighted`.

Locations: `refinement/weighted.py:65`, `refinement/weighted.py:296`. **Direct base sites:** `H-C310`.

`H-C310`: status `exactness`; checked `('packet support', 'positive path weights', 'invertible packet diagonal')`; unchecked `assumptions_unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T264 / PSC-II-T13

Declared claim: Gluing module and exact separation weight; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.lattices.LatticePacketData.gluing_module`.

Declared hypotheses: basis of the split lattice is supplied. Suite label: `refinement.lattices`.

Declared claim: Exact separation weight from the lattice action; `PROVED`; Paper II. Symbol: `komorebi_math.refinement.lattices.LatticePacketData.projector_weights`.

Declared hypotheses: rational projectors; discrete valuation at the declared prime. Suite label: `refinement.lattices`.

Locations: `refinement/lattices.py:154`, `refinement/lattices.py:192`, `refinement/lattices.py:212`. **Direct base sites:** `H-C301`.

`H-C301`: status `Exactness.EXACT`; checked `('Smith invariants', 'projector denominator valuations')`; unchecked `()`. Residual keys: `weight_difference`.

Observed examples: `EX-E-016`. **Literal test mentions:** none recorded.

H-T265 / PSC-II-T15

Source symbol(s): `komorebi_math.refinement.lattices.refinement_weight_monotonicity`. No attached provenance record under this label.

Locations: `refinement/lattices.py:274`. **Direct base sites:** `H-C302`.

`H-C302`: status `Exactness.EXACT`; checked `('common lattice', 'exact packet refinement')`; unchecked `()`. Residual keys: `monotonicity_gap`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T266 / PSC-II-T18

Declared claim: Smith weighted congruence solve; PROVED; Paper II. Symbol: komorebi_math.refinement.smith.SmithCongruenceProblem.

Declared hypotheses: integer matrix; prime power modulus. Suite label: refinement.smith.

Locations: refinement/smith.py:140, refinement/smith.py:236. **Direct base sites:** H-C307.

H-C307: status Exactness.EXACT; checked ('Smith decomposition', 'prime power modulus', 'coordinate divisibility tests'); unchecked (). Residual keys: modular_residual.

Observed examples: EX-E-016. **Literal test mentions:** none recorded.

H-T267 / PSC-II-T20

Declared claim: Power defect identity; PROVED; Paper II. Symbol: komorebi_math.refinement.defects.LinearRefinementDefect.power.

Declared hypotheses: positive integer power. Suite label: refinement.defects.

Locations: refinement/defects.py:65, refinement/defects.py:93. **Direct base sites:** H-C295.

H-C295: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('linear defect definition', 'positive exponent'); unchecked (). Residual keys: power_identity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T268 / PSC-II-T22

Declared claim: Resolvent defect identity; PROVED; Paper II. Symbol: komorebi_math.refinement.defects.LinearRefinementDefect.resolvent.

Declared hypotheses: both resolvents exist. Suite label: refinement.defects.

Locations: refinement/defects.py:134, refinement/defects.py:157. **Direct base sites:** H-C297.

H-C297: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('fine resolvent exists', 'coarse resolvent exists'); unchecked (). Residual keys: resolvent_identity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T269 / PSC-II-T24

Declared claim: Exponential defect identity; PROVED; Paper II. Symbol: komorebi_math.refinement.defects.LinearRefinementDefect.exponential.

Declared hypotheses: finite matrices. Suite label: refinement.defects.

Locations: refinement/defects.py:169, refinement/defects.py:210. **Direct base sites:** H-C298.

H-C298: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('matrix exponentials exist', 'block Duhamel identity'); unchecked (). Residual keys: exponential_identity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T270 / PSC-II-T25

Declared claim: Multilevel defect decomposition; PROVED; Paper II. Symbol: komorebi_math.refinement.defects.multilevel_defect.

Declared hypotheses: finite chain of compatible dimensions. Suite label: refinement.defects.

Locations: refinement/defects.py:244, refinement/defects.py:290. **Direct base sites:** H-C299.

H-C299: status Exactness.EXACT if algebra.exact else Exactness.NUMERICAL; checked ('adjacent dimensions', 'finite refinement chain'); unchecked (). Residual keys: multilevel_identity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T271 / PSC-III-A10

Declared claim: Projection-cached packet-jet execution plan; PROVED; Paper III scalable runtime. Symbol: komorebi_math.nonlinear.execution.PacketJetExecutionPlan.

Declared hypotheses: finite packet systems; declared zero packet blocks are certified. Suite label: nonlinear.execution.

Locations: nonlinear/execution.py:48, nonlinear/execution.py:166, nonlinear/execution.py:314. **Direct base sites:** H-C223, H-C224.

H-C223: status family.exactness; checked ('all packet-jet addresses were enumerated', 'only certified zero addresses were pruned', 'active addresses were grouped by ordered input packet tuple'); unchecked ('support classification is incomplete, so untested blocks remain active',) if support is not None and (not support.c.... Residual keys: address_partition. H-C224: status family.exactness; checked ('source directions projected once per packet', 'one derivative call per active input address', 'target packets reconstruct the retained outputs', 'prun...; unchecked ('global correctness of the derivative provider',). Residual keys: planned_reconstruction.

Observed examples: EX-E-002, EX-E-049, EX-E-050. **Literal test mentions:** none recorded.

H-T272 / PSC-III-A10G

Source symbol(s): komorebi_math.nonlinear.execution.CupyPacketJetExecutor.execute, komorebi_math.nonlinear.execution.CupyPacketJetExecutor.hardware_certificate. No attached provenance record under this label.

Locations: nonlinear/execution.py:579, nonlinear/execution.py:628. **Direct base sites:** H-C225, H-C226.

H-C225: status Exactness.NUMERICAL; checked ('CuPy installed', 'packet projectors transferred to the active device', 'device derivative provider used without host round trips inside the kernel', '...; unchecked ('cross-backend agreement with a CPU reference', 'performance comparison under a matched synchronized timing contract'). Residual keys: device_reconstruction. H-C226: status Exactness.NUMERICAL; checked ('CuPy runtime loaded', 'active CUDA device queried'); unchecked ('matched performance benchmark',). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T273 / PSC-III-A61

Declared claim: Finite packet-jet execution profile; HEURISTIC; Block 11 runtime. Symbol: komorebi_math.nonlinear.profiling.profile_packet_jet_runtime.

Declared hypotheses: fixed local process and supplied finite workload. **Declared limits:** timings are environment dependent; tracemalloc observes Python-managed allocations rather than total device or process memory. Suite label: nonlinear.profiling.

Locations: nonlinear/profiling.py:214, nonlinear/profiling.py:308, nonlinear/profiling.py:430. **Direct base sites:** H-C252, H-C253.

H-C252: status Exactness.EXACT; checked ('finite packet counts and derivative order', 'complete family address enumeration', 'execution-plan grouping and pruning certificate', 'ambient standar...; unchecked ('wall-clock cost per derivative call', 'backend-specific kernel fusion, caching, and transfer overhead'). Residual keys: address_count_mismatch. H-C253: status Exactness.HEURISTIC; checked ('all exact finite operation counts passed their structural certificate', 'every stage used the same supplied family and direction tuple', 'timing and a...; unchecked ('scheduler isolation, fixed CPU frequency, cache state, and thermal stability', 'cross-platform or cross-device comp.... Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-002. **Literal test mentions:** none recorded.

H-T274 / PSC-III-C03

Source symbol(s): `komorebi_math.nonlinear.coordinates.NonlinearPacketMap.fixed_point_residual`. No attached provenance record under this label.

Locations: `nonlinear/coordinates.py:99`. **Direct base sites:** `H-C208`.

`H-C208`: status `Exactness.EXACT if self.source.backend.exact else Exactness.NUMERICAL`; checked `('source and target packet equivalence',)`; unchecked `()`. Residual keys: `fixed_point_residual_norm`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T275 / PSC-III-C08

Declared claim: Finite packet jet support test; `FINITE_CERTIFICATE`; Paper III runtime. Symbol: `komorebi_math.nonlinear.jets.packet_jet_support`.

Declared hypotheses: finite dimensional packet ranges; basis test of a multilinear map. Suite label: `nonlinear.jets`.

Locations: `nonlinear/jets.py:343`, `nonlinear/jets.py:408`. **Direct base sites:** `H-C245`.

`H-C245`: status `exactness`; checked `('packet range bases', 'multilinearity', 'tested packet addresses')`; unchecked `('untested addresses due to evaluation limit',) if untested else ()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-002`, `EX-E-031`, `EX-E-049`, `EX-E-050`. **Literal test mentions:** none recorded.

H-T276 / PSC-III-C09

Declared claim: Finite packet Taylor reconstruction; `FINITE_CERTIFICATE`; Paper III. Symbol: `komorebi_math.nonlinear.jets.packet_taylor`.

Declared hypotheses: declared derivatives through the truncation order. **Declared limits:** no automatic bound on the omitted Taylor remainder. Suite label: `nonlinear.jets`.

Locations: `nonlinear/jets.py:440`, `nonlinear/jets.py:492`. **Direct base sites:** `H-C246`.

`H-C246`: status `exactness`; checked `('packet reconstruction of every retained derivative order',)`; unchecked `('Taylor remainder beyond the retained order', 'global correctness of user supplied derivatives')`. Residual keys: `observed_truncation_residual`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T277 / PSC-III-C15

Source symbol(s): `komorebi_math.nonlinear.trees.quadratic_catalan_majorant`. No attached provenance record under this label.

Locations: `nonlinear/trees.py:421`. **Direct base sites:** `H-C270`.

`H-C270`: status `Exactness.NUMERICAL`; checked `('nonnegative scalar norms',)`; unchecked `result.certificate.assumptions_unchecked`. Residual keys: `catalan_discriminant_defect`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T278 / PSC-III-C34

Source symbol(s): `komorebi_math.nonlinear.correction.LyapunovSchmidtReduction.reduced_second_derivative`. No attached provenance record under this label.

Locations: `nonlinear/correction.py:517`. **Direct base sites:** `H-C215`.

`H-C215`: status `Exactness.NUMERICAL`; checked `('kernel input projection', 'cokernel output projection')`; unchecked `('declared second derivative is globally correct',)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T279 / PSC-III-C60

Source symbol(s): `komorebi_math.nonlinear.transport.KatoTransport.refinement_certificate`. No attached provenance record under this label.

Locations: `nonlinear/transport.py:451`. **Direct base sites:** `H-C268`.

`H-C268`: status `Exactness.NUMERICAL`; checked `('nested midpoint discretizations', 'endpoint residual comparison')`; unchecked `('asymptotic convergence outside the two sampled resolutions',)`. Residual keys: `coarse_fine_difference`, `endpoint_intertwining`.

Observed examples: `EX-E-019`. **Literal test mentions:** none recorded.

H-T280 / PSC-III-D01

Declared claim: Nonlinear packet coordinate map; `DEFINITION`; Paper III. Symbol: `komorebi_math.nonlinear.coordinates.NonlinearPacketMap`.

Declared hypotheses: finite source and target packet systems. Suite label: `nonlinear.coordinates`.

Locations: `nonlinear/coordinates.py:15`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T281 / PSC-III-D02

Declared claim: Declared finite dimensional derivative provider; `DEFINITION`; Paper III runtime. Symbol: `komorebi_math.nonlinear.derivatives.CallableDerivativeProvider`.

Declared hypotheses: declared directional derivatives. Suite label: `nonlinear.derivatives`.

Locations: `nonlinear/derivatives.py:96`, `nonlinear/derivatives.py:227`. **Direct base sites:** `H-C217`.

`H-C217`: status `self.exactness`; checked `('source and target dimensions', 'finite derivative symmetry probes')`; unchecked `tuple(unchecked)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T282 / PSC-III-D04

Declared claim: Symmetric polynomial derivative tensors; `DEFINITION`; Paper III runtime. Symbol: `komorebi_math.nonlinear.derivatives.PolynomialDerivativeProvider`.

Declared hypotheses: declared symmetric coefficient tensors. Suite label: `nonlinear.derivatives`.

Locations: `nonlinear/derivatives.py:317`, `nonlinear/derivatives.py:464`. **Direct base sites:** `H-C218`.

`H-C218`: status `self.exactness`; checked `('tensor dimensions', 'adjacent source-axis symmetry')`; unchecked `()`. Residual keys: `tensor_symmetry`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T283 / PSC-III-D04P

Declared claim: Sparse polynomial derivative provider; `DEFINITION`; Paper III scalable runtime. Symbol: `komorebi_math.nonlinear.sparse.SparsePolynomialDerivativeProvider`.

Declared hypotheses: finite sparse symmetric coefficient tensors. Suite label: `nonlinear.sparse`.

Locations: `nonlinear/sparse.py:345`, `nonlinear/sparse.py:619`. **Direct base sites:** `H-C257`.

`H-C257`: status `Exactness.EXACT if exact else Exactness.NUMERICAL`; checked `('symmetric orbit expansion', 'finite value probes', 'finite directional derivative probes')`; unchecked `('global equality beyond the supplied probes',) if probes else ()`. Residual keys: `sparse_dense_equivalence`.

Observed examples: `EX-E-050`. **Literal test mentions:** none recorded.

H-T284 / PSC-III-D04S

Declared claim: Sparse symmetric derivative tensor; `DEFINITION`; Paper III scalable runtime. Symbol: `komorebi_math.nonlinear.sparse.SparseSymmetricTensor`.

Declared hypotheses: finite dimensions; symmetric source axes. Suite label: `nonlinear.sparse`.

Locations: `nonlinear/sparse.py:99`, `nonlinear/sparse.py:313`. **Direct base sites:** `H-C256`.

`H-C256`: status `exactness`; checked `('canonical symmetric orbit keys', 'dense expansion', 'dense recompression')`; unchecked `()`. Residual keys: `dense_roundtrip`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T285 / PSC-III-D06

Declared claim: Finite packet jet; `DEFINITION`; Paper III. Symbol: `komorebi_math.nonlinear.jets.PacketJet`.

Declared hypotheses: finite packet systems; declared finite dimensional derivative provider. Suite label: `nonlinear.jets`.

Locations: `nonlinear/jets.py:71`, `nonlinear/jets.py:180`. **Direct base sites:** `H-C243`.

`H-C243`: status `self.exactness`; checked `('symmetric declared derivative', 'corresponding packet address permutation')`; unchecked `('global correctness of user supplied derivatives',)`. Residual keys: `jet_symmetry`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T286 / PSC-III-D10

Declared claim: Nonlinear refinement defect; `DEFINITION`; Paper III. Symbol: `komorebi_math.nonlinear.defects.NonlinearRefinementDefect`.

Declared hypotheses: fine and coarse maps; linear coarsening maps. Suite label: `nonlinear.defects`.

Locations: `nonlinear/defects.py:20`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T287 / PSC-III-D12

Declared claim: Composed derivative provider; `DEFINITION`; Paper III runtime. Symbol: `komorebi_math.nonlinear.composition.ComposedDerivativeProvider`.

Declared hypotheses: compatible finite dimensional derivative providers. Suite label: `nonlinear.composition`.

Locations: `nonlinear/composition.py:390`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T288 / PSC-III-D13

Declared claim: Linear correction datum and cokernel obstruction; `DEFINITION`; Paper III. Symbol: `komorebi_math.nonlinear.obstruction.LinearObstructionProblem`.

Declared hypotheses: finite dimensional linear correction map. Suite label: `nonlinear.obstruction`.

Declared claim: Finite ordered rooted tree; `DEFINITION`; Paper III. Symbol: `komorebi_math.nonlinear.trees.OrderedRootedTree`.

Declared hypotheses: ordered children; internal arity at least two. Suite label: `nonlinear.trees`.

Locations: `nonlinear/obstruction.py:36`, `nonlinear/trees.py:98`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T289 / PSC-III-D17

Declared claim: Finite abelian grading group; `DEFINITION`; Paper III runtime. Symbol: `komorebi_math.nonlinear.graded.FiniteAbelianGroup`.

Declared hypotheses: finite explicit operation table. Suite label: `nonlinear.graded`.

Locations: `nonlinear/graded.py:75`, `nonlinear/graded.py:165`. **Direct base sites:** `H-C234`.

`H-C234`: status `Exactness.EXACT`; checked `('closure', 'identity', 'inverses', 'commutativity', 'associativity')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T290 / PSC-III-D38

Declared claim: Finite matrix transport system; `DEFINITION`; Paper III. Symbol: `komorebi_math.nonlinear.holonomy.TransportGraph`.

Declared hypotheses: connected finite graph; invertible edge transports; one model fiber dimension. Suite label: `nonlinear.holonomy`.

Locations: `nonlinear/holonomy.py:48`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T291 / PSC-III-D50

Declared claim: Finite decreasing filtration over a prime field; `DEFINITION`; Paper III runtime. Symbol: `komorebi_math.nonlinear.filtered.FilteredVectorSpace`.

Declared hypotheses: explicit nested finite-dimensional subspaces. Suite label: `nonlinear.filtered`.

Locations: `nonlinear/filtered.py:179`, `nonlinear/filtered.py:286`. **Direct base sites:** `H-C227`.

`H-C227`: status `Exactness.EXACT`; checked `('full F^0', 'nested levels', 'terminal zero level')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T292 / PSC-III-D56

Declared claim: Smooth finite packet system; `DEFINITION`; Paper III shared runtime. Symbol: `komorebi_math.nonlinear.transport.MovingPacketSystem`.

Declared hypotheses: declared differentiable complete orthogonal packet family. Suite label: `nonlinear.transport`.

Locations: `nonlinear/transport.py:149`, `nonlinear/transport.py:247`. **Direct base sites:** `H-C264`.

`H-C264`: status `Exactness.NUMERICAL`; checked `('centered finite-difference comparison', 'differentiated projector identity', 'differentiated partition of unity')`; unchecked `('analytic differentiability beyond the sampled point',)`. Residual keys: `finite_difference`, `projector_tangent`, `partition_derivative`.

Observed examples: `EX-E-019`. **Literal test mentions:** none recorded.

H-T293 / PSC-III-D58

Declared claim: Finite packet-jet snapshot; FINITE_CERTIFICATE; Block 10 runtime. Symbol: komorebi_math.nonlinear.snapshots.PacketJetSnapshot.

Declared hypotheses: finite dimensional multilinear packet jet. **Declared limits:** snapshot represents one fixed order, address, and base point. Suite label: nonlinear.snapshots.

Locations: nonlinear/snapshots.py:80, nonlinear/snapshots.py:246, nonlinear/snapshots.py:332. **Direct base sites:** H-C254, H-C255.

H-C254: status self.exactness; checked ('matching packet address', 'matching finite dimensions'); unchecked ('probes not supplied to this finite comparison',). Residual keys: snapshot_reconstruction. H-C255: status jet.exactness; checked ('complete ambient standard basis', 'finite multilinearity', 'fixed packet address and base point'); unchecked ('global correctness of the underlying derivative provider',). Residual keys: maximum_omitted_basis_norm.

Observed examples: EX-E-002, EX-E-037, EX-E-049. **Literal test mentions:** none recorded.

H-T294 / PSC-III-D60

Declared claim: Chunked resumable packet-jet capture; FINITE_CERTIFICATE; Block 11 runtime. Symbol: komorebi_math.nonlinear.streaming.capture_packet_jet_stream.

Declared hypotheses: finite-dimensional multilinear packet jet. **Declared limits:** integrity digests are not signatures; resuming assumes the provider behavior still agrees with its recorded identity. Suite label: nonlinear.streaming.

Locations: nonlinear/streaming.py:966, nonlinear/streaming.py:997, nonlinear/streaming.py:1131, nonlinear/streaming.py:1441, nonlinear/streaming.py:1508, nonlinear/streaming.py:1584. **Direct base sites:** H-C258, H-C259, H-C260, H-C261, H-C262.

H-C258: status manifest.exactness if completed else Exactness.CONDITIONAL; checked ('every committed chunk has an independent SHA-256 payload digest', 'manifest progress is updated only after an atomic chunk write', 'source metadata ma...; unchecked unchecked. Residual keys: remaining_basis_evaluations, incomplete_stream. H-C259: status jet.exactness; checked ('complete ambient standard basis', 'finite multilinearity', 'fixed packet address and base point', 'each committed chunk passed atomic write and digest...; unchecked ('global correctness of the underlying derivative provider',). Residual keys: maximum_omitted_basis_norm. H-C260: status self.manifest.exactness; checked ('selected chunks passed envelope and manifest digest validation', 'coefficient ordinal bounds were enforced'); unchecked () if complete_snapshot else ('coefficients outside the selected ordinal interval were not loaded',). Residual keys: missing_selected_coefficients. H-C261: status self.manifest.exactness; checked ('each contributing chunk passed digest validation', 'ordered multilinear coefficient contraction'); unchecked () if complete_snapshot else ('the returned value is only the selected coefficient partial sum',). Residual keys: unprocessed_selected_coefficients. H-C262: status Exactness.EXACT; checked ('manifest envelope digest', 'metadata digest', 'stream content digest', 'every chunk envelope digest and manifest cross-reference', 'contiguous basis a... ; unchecked ('SHA-256 integrity does not establish authenticity or authorship',). Residual keys: coefficient_count_mismatch, basis_count_mismatch, coefficient_ordering_violations.

Observed examples: EX-E-002, EX-E-048. **Literal test mentions:** none recorded.

H-T295 / PSC-III-E05

Declared claim: Exact symbolic directional derivatives; FINITE_CERTIFICATE; SymPy adapter. Symbol: komorebi_math.nonlinear.derivatives.SympyDerivativeProvider.

Declared hypotheses: SymPy expressions and substitution values are exact. Suite label: nonlinear.derivatives.

Locations: nonlinear/derivatives.py:476. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T296 / PSC-III-LIN-FP

Declared claim: Linear correction space over a prime field; `CLASSICAL`; Paper III. Symbol: `komorebi_math.nonlinear.lifting.solve_mod_prime`.

Declared hypotheses: prime modulus. Suite label: `nonlinear.lifting`.

Locations: `nonlinear/lifting.py:82`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T297 / PSC-III-N03

Declared claim: Recursive central directional differences; `FINITE_CERTIFICATE`; Numerical runtime. Symbol: `komorebi_math.nonlinear.derivatives.FiniteDifferenceDerivativeProvider`.

Declared hypotheses: sufficient smoothness near the evaluation point; finite difference scale resolves the derivative. **Declared limits:** roundoff and truncation error grow with derivative order. Suite label: `nonlinear.derivatives`.

Locations: `nonlinear/derivatives.py:241`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T298 / PSC-III-N04A

Declared claim: Directional automatic-differentiation adapter; `DEFINITION`; Paper III scalable runtime. Symbol: `komorebi_math.nonlinear.autodiff.AutomaticDifferentiationProvider`.

Declared hypotheses: declared forward-mode JVP primitive. Suite label: `nonlinear.autodiff`.

Locations: `nonlinear/autodiff.py:227`, `nonlinear/autodiff.py:354`, `nonlinear/autodiff.py:448`. **Direct base sites:** `H-C203`, `H-C204`.

`H-C203`: status `self.exactness`; checked `('finite source and target dimensions', 'permutation symmetry probes')`; unchecked `('global correctness of the supplied JVP primitive', 'framework tracing outside the tested points')`. Residual keys: `directional_symmetry`. `H-C204`: status `Exactness.NUMERICAL`; checked `('finite source and target dimensions', 'permutation symmetry probes')`; unchecked `('global correctness of the external automatic-differentiation runtime', 'framework tracing outside the tested points')`. Residual keys: `directional_symmetry`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T299 / PSC-III-N04J

Declared claim: Lazy JAX derivative adapter; `FINITE_CERTIFICATE`; External automatic-differentiation adapter. Symbol: `komorebi_math.nonlinear.autodiff.JaxDerivativeProvider`.

Declared hypotheses: compatible JAX installation; JAX-traceable function. **Declared limits:** device and precision behavior are controlled by the external JAX runtime. Suite label: `nonlinear.autodiff`.

Locations: `nonlinear/autodiff.py:472`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T300 / PSC-III-N04T

Declared claim: Lazy PyTorch derivative adapter; `FINITE_CERTIFICATE`; External automatic-differentiation adapter. Symbol: `komorebi_math.nonlinear.autodiff.TorchDerivativeProvider`.

Declared hypotheses: compatible PyTorch installation; torch.func.jvp-compatible function. **Declared limits:** device and precision behavior are controlled by the external PyTorch runtime. Suite label: `nonlinear.autodiff`.

Locations: `nonlinear/autodiff.py:571`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T301 / PSC-III-N59

Declared claim: Sparse CuPy packet-jet execution; `FINITE_CERTIFICATE`; Block 10 runtime. Symbol: `komorebi_math.nonlinear.gpu.CuPySnapshotExecutor`.

Declared hypotheses: captured finite packet jet; working CuPy CUDA runtime. **Declared limits:** no performance claim without matched hardware benchmarking. Suite label: `nonlinear.gpu`.

Locations: `nonlinear/gpu.py:64`, `nonlinear/gpu.py:165`. **Direct base sites:** `H-C233`.

`H-C233`: status `Exactness.NUMERICAL`; checked `('matched snapshot coefficients', 'matched probe directions', 'actual CuPy CUDA execution')`; unchecked `('performance comparison and timing-scope equivalence', 'behavior outside the supplied finite probes')`. Residual keys: `maximum_cpu_gpu_residual`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T302 / PSC-III-P20

Declared claim: Finite truncated packet equations for higher operations; `PROVED`; Paper III. Symbol: `komorebi_math.nonlinear.graded.higher_maurer_cartan_packets`.

Declared hypotheses: finite truncation; grade-respecting multilinear operations; factorials invertible. **Declared limits:** does not certify convergence of an infinite Maurer–Cartan series. Suite label: `nonlinear.graded`.

Locations: `nonlinear/graded.py:481`, `nonlinear/graded.py:540`. **Direct base sites:** `H-C239`.

`H-C239`: status `exactness`; checked `('finite higher-operation truncation', 'label convolution')`; unchecked `('operations are multilinear and grade respecting', 'convergence of any omitted infinite tail')`. Residual keys: `higher_packet_reconstruction`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T303 / PSC-III-P21

Source symbol(s): `komorebi_math.nonlinear.graded.divided_square_packets`. No attached provenance record under this label.

Locations: `nonlinear/graded.py:608`. **Direct base sites:** `H-C240`.

`H-C240`: status `exactness`; checked `('ordered cross-label pairs', 'finite label convolution')`; unchecked `('declared divided-square polarization identity', 'grading compatibility')`. Residual keys: `divided_square_packet_reconstruction`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T304 / PSC-III-S54

Declared claim: Spectral sequence of a finite filtered complex; CLASSICAL; Paper III. Symbol: komorebi_math.nonlinear.filtered.FiniteFilteredCochainComplex.

Declared hypotheses: bounded finite cochain complex; finite decreasing filtration by subcomplexes. Suite label: nonlinear.filtered.

Locations: nonlinear/filtered.py:611, nonlinear/filtered.py:767, nonlinear/filtered.py:809. **Direct base sites:** H-C231, H-C232.

H-C231: status Exactness.EXACT; checked ('Z_r and B_r subquotients', 'induced differential ranks'); unchecked (). Residual keys: page_cohomology_relation_failures. H-C232: status Exactness.EXACT; checked ('finite filtration by subcomplexes', 'page-to-page cohomology identities', 'limiting dimensions equal total cohomology dimensions'); unchecked (). Residual keys: convergence_dimension_mismatches, limiting_differential_rank.

Observed examples: EX-E-019. **Literal test mentions:** none recorded.

H-T305 / PSC-III-T02

Declared claim: Exact nonlinear packet coordinate theorem; PROVED; Paper III. Symbol: komorebi_math.nonlinear.coordinates.NonlinearPacketMap.certificate.

Declared hypotheses: exact packet analysis and synthesis. Suite label: nonlinear.coordinates.

Locations: nonlinear/coordinates.py:56, nonlinear/coordinates.py:72. **Direct base sites:** H-C207.

H-C207: status Exactness.EXACT if self.source.backend.exact else Exactness.NUMERICAL; checked ('source reconstruction', 'target analysis', 'function evaluation'); unchecked (). Residual keys: coordinate_conjugacy.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T306 / PSC-III-T07

Declared claim: Exact reconstruction of finite packet derivatives; PROVED; Paper III. Symbol: komorebi_math.nonlinear.jets.PacketJetFamily.

Declared hypotheses: complete finite packet systems; multilinear derivative. Suite label: nonlinear.jets.

Locations: nonlinear/jets.py:202, nonlinear/jets.py:295. **Direct base sites:** H-C244.

H-C244: status self.exactness; checked ('complete input packets', 'complete output packets', 'multilinearity'); unchecked ('global correctness of user supplied derivatives',). Residual keys: derivative_reconstruction.

Observed examples: EX-E-031. **Literal test mentions:** none recorded.

H-T307 / PSC-III-T10

Declared claim: Finite dimensional Faà di Bruno formula; CLASSICAL; Classical higher chain rule used in Paper III. Symbol: komorebi_math.nonlinear.composition.faa_di_bruno.

Declared hypotheses: declared derivatives through the requested order. Suite label: nonlinear.composition.

Locations: nonlinear/composition.py:134, nonlinear/composition.py:204. **Direct base sites:** H-C205.

H-C205: status exactness; checked ('set partition enumeration', 'higher chain rule assembly'); unchecked tuple(assumptions_unchecked). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-031. **Literal test mentions:** none recorded.

H-T308 / PSC-III-T11

Declared claim: Exact nonlinear defect under composition; PROVED; Paper III. Symbol: komorebi_math.nonlinear.defects.NonlinearRefinementDefect.composition_identity.

Declared hypotheses: composable fine and coarse maps. Suite label: nonlinear.defects.

Locations: nonlinear/defects.py:47, nonlinear/defects.py:78. **Direct base sites:** H-C216.

H-C216: status Exactness.NUMERICAL; checked ('pointwise map evaluation',); unchecked (). Residual keys: composition_identity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T309 / PSC-III-T11A

Declared claim: Packet Faà di Bruno formula; PROVED; Paper III. Symbol: komorebi_math.nonlinear.composition.packet_faa_di_bruno.

Declared hypotheses: complete finite packet systems; declared higher derivatives. Suite label: nonlinear.composition.

Locations: nonlinear/composition.py:231, nonlinear/composition.py:364. **Direct base sites:** H-C206.

H-C206: status exactness; checked ('set partition enumeration', 'complete intermediate packet identity', 'input and output packet projection', 'declared zero supports used only for pruni...; unchecked ('global correctness of declared derivative providers',). Residual keys: packet_composition_reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T310 / PSC-III-T14

Declared claim: Cokernel obstruction criterion; PROVED; Paper III. Symbol: komorebi_math.nonlinear.obstruction.LinearObstructionProblem.solve.

Declared hypotheses: finite dimensional correction problem. Suite label: nonlinear.obstruction.

Declared claim: Polynomial rooted-tree convergence certificate; PROVED; Paper III, polynomial tree expansion theorem. Symbol: komorebi_math.nonlinear.trees.majorant_convergence.

Declared hypotheses: declared multilinear norm bounds; closed Banach ball; majorant contraction. Suite label: nonlinear.trees.

Locations: nonlinear/obstruction.py:64, nonlinear/obstruction.py:99, nonlinear/obstruction.py:130, nonlinear/trees.py:327, nonlinear/trees.py:370. **Direct base sites:** H-C249, H-C250, H-C269.

H-C249: status Exactness.EXACT; checked ('exact rank comparison', 'left nullspace quotient coordinates', 'kernel basis'); unchecked (). Residual keys: correction_residual. H-C250: status Exactness.NUMERICAL; checked ('least squares correction', 'orthogonal cokernel coordinates', 'numerical rank'); unchecked (). Residual keys: correction_residual, obstruction_coordinate_norm. H-C269: status Exactness.NUMERICAL; checked ('nonnegative declared norm bounds', 'majorant maps declared ball into itself', 'majorant derivative is strictly below one'); unchecked ('declared operation bounds dominate the actual multilinear norms', 'ambient space is complete'). Residual keys: ball_image_excess, contraction_excess.

Observed examples: EX-E-032, EX-E-033. **Literal test mentions:** none recorded.

H-T311 / PSC-III-T14A

Declared claim: Finite polynomial rooted-tree expansion; FINITE_CERTIFICATE; Paper III. Symbol: komorebi_math.nonlinear.trees.PolynomialFixedPointProblem.

Declared hypotheses: finite-dimensional declared multilinear operations. Suite label: nonlinear.trees.

Locations: nonlinear/trees.py:459, nonlinear/trees.py:577. **Direct base sites:** H-C271.

H-C271: status self.exactness; checked ('ordered tree enumeration', 'recursive multilinear evaluation'); unchecked ('convergence beyond the finite depth',). Residual keys: tree_sum_minus_picard.

Observed examples: EX-E-032. **Literal test mentions:** none recorded.

H-T312 / PSC-III-T15

Source symbol(s): komorebi_math.nonlinear.obstruction.ObstructionSquare.certificate. No attached provenance record under this label.

Locations: nonlinear/obstruction.py:180. **Direct base sites:** H-C251.

H-C251: status Exactness.EXACT if algebra.exact else Exactness.NUMERICAL; checked ('linear square dimensions',); unchecked (). Residual keys: commuting_square.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T313 / PSC-III-T16

Declared claim: Packet-labeled rooted-tree reconstruction; PROVED; Paper III. Symbol: komorebi_math.nonlinear.trees.packet_tree_reconstruction.

Declared hypotheses: complete finite packet system; declared multilinear vertex maps. Suite label: nonlinear.trees.

Locations: nonlinear/trees.py:627, nonlinear/trees.py:701. **Direct base sites:** H-C272.

H-C272: status exactness; checked ('complete packet identity at every input and output slot', 'finite recursive tree evaluation', 'declared zero blocks used only for pruning'); unchecked ('global correctness of declared multilinear operations',). Residual keys: packet_tree_reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T314 / PSC-III-T18

Declared claim: Graded packet convolution; PROVED; Paper III. Symbol: komorebi_math.nonlinear.graded.GradedPacketOperation.

Declared hypotheses: finite group grading; grade-respecting multilinear operation. Suite label: nonlinear.graded.

Locations: nonlinear/graded.py:204, nonlinear/graded.py:306, nonlinear/graded.py:362. **Direct base sites:** H-C236, H-C237.

H-C236: status exactness; checked ('packet-range bases', 'forbidden output packets', 'tested label tuples'); unchecked ('unseen label tuples due to evaluation limit',) if not complete else (). Residual keys: forbidden_packet_output. H-C237: status exactness; checked ('complete input packets', 'output label sum enumeration'); unchecked ('operation respects the grading globally',). Residual keys: graded_convolution_reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T315 / PSC-III-T19

Declared claim: Packet Maurer–Cartan equations; PROVED; Paper III. Symbol: komorebi_math.nonlinear.graded.maurer_cartan_packets.

Declared hypotheses: grading-preserving differential; grade-additive bracket; two invertible. Suite label: nonlinear.graded.

Locations: nonlinear/graded.py:409, nonlinear/graded.py:454. **Direct base sites:** H-C238.

H-C238: status exactness; checked ('finite group label convolution', 'packet equation reconstruction at supplied components'); unchecked ('differential is linear', 'bracket is bilinear and grade respecting'). Residual keys: packet_maurer_cartan_reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T316 / PSC-III-T28

Declared claim: One step lifting criterion; PROVED; Paper III. Symbol: komorebi_math.nonlinear.lifting.LinearLiftProblem.

Declared hypotheses: current point solves through the declared depth; linearized correction law. Suite label: nonlinear.lifting.

Locations: nonlinear/lifting.py:173, nonlinear/lifting.py:214, nonlinear/lifting.py:339. **Direct base sites:** H-C247, H-C248.

H-C247: status Exactness.EXACT; checked ('current congruence', 'associated graded correction equation'); unchecked (). Residual keys: child_verification. H-C248: status exactness; checked ('current polynomial congruence', 'all computed children') + (('Jacobian linearization over every residual correction',) if linearization_verified else ()); unchecked assumptions_unchecked. Residual keys: child_verification.

Observed examples: EX-E-033. **Literal test mentions:** none recorded.

H-T317 / PSC-III-T30

Declared claim: Finite lift tree construction; PROVED; Paper III. Symbol: komorebi_math.nonlinear.lifting.build_lift_tree.

Declared hypotheses: finite residue field; finite correction spaces. Suite label: nonlinear.lifting.

Locations: nonlinear/lifting.py:421. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T318 / PSC-III-T31

Declared claim: Orthogonal Hilbert obstruction projector; CLASSICAL; Paper III. Symbol: komorebi_math.nonlinear.correction.HilbertObstructionProjector.

Declared hypotheses: finite-dimensional Hilbert spaces; numerically resolved singular-value rank. Suite label: nonlinear.correction.

Locations: nonlinear/correction.py:57, nonlinear/correction.py:112. **Direct base sites:** H-C209.

H-C209: status Exactness.NUMERICAL; checked ('singular-value rank', 'Moore--Penrose pseudoinverse', 'orthogonal image and cokernel projectors'); unchecked ('rank stability below the singular-value threshold',). Residual keys: correction_residual, distance_identity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T319 / PSC-III-T32

Declared claim: Right-inverse nonlinear correction; PROVED; Paper III. Symbol: komorebi_math.nonlinear.correction.RightInverseCorrectionProblem.

Declared hypotheses: declared right inverse; declared Lipschitz bound; invariant contraction ball. Suite label: nonlinear.correction.

Locations: nonlinear/correction.py:152, nonlinear/correction.py:213, nonlinear/correction.py:266. **Direct base sites:** H-C210, H-C211.

H-C210: status Exactness.NUMERICAL; checked ('D R equals identity numerically', 'declared contraction factor below one', 'declared ball invariance inequality'); unchecked ('declared Lipschitz bound holds throughout the ball',). Residual keys: right_inverse, invariant_ball_excess. H-C211: status Exactness.NUMERICAL; checked hypothesis.assumptions_checked + ('fixed-point convergence in the declared ball',); unchecked hypothesis.assumptions_unchecked. Residual keys: equation, fixed_point.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T320 / PSC-III-T33

Declared claim: Finite local Lyapunov–Schmidt reduction; CLASSICAL; Paper III. Symbol: komorebi_math.nonlinear.correction.LyapunovSchmidtReduction.

Declared hypotheses: C1 finite-dimensional map; constant resolved rank near the base point; local implicit-function neighborhood. Suite label: nonlinear.correction.

Locations: nonlinear/correction.py:326, nonlinear/correction.py:384, nonlinear/correction.py:467, nonlinear/correction.py:491. **Direct base sites:** H-C212, H-C213, H-C214.

H-C212: status Exactness.NUMERICAL; checked ('SVD kernel/range decomposition', 'invertibility on the resolved complement'); unchecked ('rank is stable in a neighborhood of the base point',). Residual keys: restricted_inverse. H-C213: status Exactness.NUMERICAL; checked ('local range equation solved numerically',); unchecked ('the selected point remains in an implicit-function neighborhood', 'local solution branch is the unique branch repre... Residual keys: range_equation. H-C214: status Exactness.NUMERICAL; checked ('kernel and cokernel SVD identities',); unchecked ('local differentiability of the selected implicit branch',). Residual keys: Dpsi_at_base, Dkappa_at_base.

Observed examples: EX-E-032. **Literal test mentions:** none recorded.

H-T321 / PSC-III-T39

Declared claim: Spanning tree normalization; PROVED; Paper III. Symbol: komorebi_math.nonlinear.holonomy.TransportGraph.tree_gauge.

Declared hypotheses: connected transport graph. Suite label: nonlinear.holonomy.

Locations: nonlinear/holonomy.py:165. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T322 / PSC-III-T40

Declared claim: Fundamental cycle holonomy criterion; PROVED; Paper III. Symbol: komorebi_math.nonlinear.holonomy.TransportGraph.fundamental_holonomies.

Declared hypotheses: connected finite graph. Suite label: nonlinear.holonomy.

Locations: nonlinear/elimination.py:445, nonlinear/elimination.py:477, nonlinear/holonomy.py:197, nonlinear/holonomy.py:234. **Direct base sites:** H-C221, H-C222, H-C241.

H-C221: status Exactness.NUMERICAL; checked ('damped Newton solution of the hidden equation',); unchecked ('the computed branch remains in the local implicit-function neighborhood', 'no other remote hidden solution is repre... Residual keys: hidden_equation. H-C222: status Exactness.NUMERICAL; checked ('hidden equation solved', 'retained equation evaluated on the branch'); unchecked solve.certificate.assumptions_unchecked. Residual keys: hidden_equation. H-C241: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('spanning tree normalization', 'fundamental cycle basis'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-025. **Literal test mentions:** none recorded.

H-T323 / PSC-III-T41

Declared claim: Finite nonlinear Schur elimination; PROVED; Paper III. Symbol: komorebi_math.nonlinear.elimination.NonlinearSchurElimination.

Declared hypotheses: C2 split equation; invertible hidden derivative; local implicit-function branch. Suite label: nonlinear.elimination.

Declared claim: Fundamental holonomy intertwining criterion; PROVED; Paper III. Symbol: komorebi_math.nonlinear.holonomy.TransportGraph.intertwine.

Declared hypotheses: two transport systems on the same graph; root intertwiner. Suite label: nonlinear.holonomy.

Locations: nonlinear/elimination.py:176, nonlinear/elimination.py:280, nonlinear/holonomy.py:246, nonlinear/holonomy.py:308. **Direct base sites:** H-C219, H-C242.

H-C219: status self.exactness; checked ('hidden derivative inversion', 'first-order Schur formula'); unchecked ('existence of a local implicit-function neighborhood',). Residual keys: hidden_inverse. H-C242: status Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL; checked ('common graph', 'tree propagated vertex intertwiners', 'fundamental cycle tests'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-032. **Literal test mentions:** none recorded.

H-T324 / PSC-III-T42

Source symbol(s): `komorebi_math.nonlinear.elimination.NonlinearSchurElimination.second_derivative`. No attached provenance record under this label.

Locations: `nonlinear/elimination.py:348`. **Direct base sites:** `H-C220`.

`H-C220`: status `self.exactness`; checked `('lifted retained directions', 'second-order hidden feedback')`; unchecked `('existence and C2 regularity of the local implicit branch',)`. Residual keys: `second_schur_formula`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T325 / PSC-III-T51

Declared claim: One-step filtered lifting criterion; `PROVED`; Paper III. Symbol: `komorebi_math.nonlinear.filtered.FilteredCorrectionProblem`.

Declared hypotheses: filtration-preserving correction map at the requested depth. Suite label: `nonlinear.filtered`.

Locations: `nonlinear/filtered.py:320`, `nonlinear/filtered.py:397`. **Direct base sites:** `H-C228`.

`H-C228`: status `Exactness.EXACT`; checked `('filtration preservation at consecutive levels', 'associated graded correction equation', 'all enumerated corrections improve the defect by one level')`; unchecked `()`. Residual keys: `child_verification`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T326 / PSC-III-T52

Source symbol(s): `komorebi_math.nonlinear.filtered.verify_finite_filtered_branch`. No attached provenance record under this label.

Locations: `nonlinear/filtered.py:476`. **Direct base sites:** `H-C229`.

`H-C229`: status `Exactness.EXACT`; checked `('successive congruence compatibility', 'defect depth at every finite level')`; unchecked `() if terminal_reached else ('continuation beyond the verified finite prefix',)`. Residual keys: `compatibility_failures`, `defect_depth_failures`, `terminal_defect`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T327 / PSC-III-T53

Source symbol(s): `komorebi_math.nonlinear.filtered.conditional_projective_limit_completion`. No attached provenance record under this label.

Locations: `nonlinear/filtered.py:546`. **Direct base sites:** `H-C230`.

`H-C230`: status `Exactness.CONDITIONAL`; checked `tuple((name.replace('_', ' ') for name, enabled in flags.items() if enabled))`; unchecked `unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T328 / PSC-III-T55

Declared claim: Direct rotation of finite packet systems; `PROVED`; Paper III shared runtime. Symbol: `komorebi_math.nonlinear.transport.direct_packet_rotation`.

Declared hypotheses: two complete orthogonal packet systems; invertible overlap sum. Suite label: `nonlinear.transport`.

Locations: `nonlinear/transport.py:98`, `nonlinear/transport.py:136`. **Direct base sites:** `H-C263`.

`H-C263`: status `Exactness.NUMERICAL`; checked `('complete orthogonal packets', 'invertible overlap sum')`; unchecked `()`. Residual keys: `unitarity`, `intertwining`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T329 / PSC-III-T57

Source symbol(s): `komorebi_math.nonlinear.transport.MovingPacketSystem.generator_certificate`. No attached provenance record under this label.

Locations: `nonlinear/transport.py:289`. **Direct base sites:** `H-C265`.

`H-C265`: status `Exactness.NUMERICAL`; checked `('declared differentiable packet family',)`; unchecked `()`. Residual keys: `skew_adjoint`, `projector_commutator`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T330 / PSC-III-T58

Declared claim: Finite smooth packet transport; `PROVED`; Paper III shared runtime. Symbol: `komorebi_math.nonlinear.transport.KatoTransport`.

Declared hypotheses: differentiable complete orthogonal packet family. Suite label: `nonlinear.transport`.

Locations: `nonlinear/transport.py:301`, `nonlinear/transport.py:356`. **Direct base sites:** `H-C266`.

`H-C266`: status `Exactness.NUMERICAL`; checked `('midpoint integration of the sampled canonical generator',)`; unchecked `('global higher-order integration error beyond residual checks',)`. Residual keys: `intertwining`, `unitarity`, `generator_failures`.

Observed examples: `EX-E-019`, `EX-E-026`. **Literal test mentions:** none recorded.

H-T331 / PSC-III-T59

Source symbol(s): `komorebi_math.nonlinear.transport.KatoTransport.direct_rotation_product`. No attached provenance record under this label.

Locations: `nonlinear/transport.py:399`. **Direct base sites:** `H-C267`.

`H-C267`: status `Exactness.NUMERICAL`; checked `('invertible overlap at every partition step',)`; unchecked `()`. Residual keys: `endpoint_intertwining`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T332 / PSC-IV-T01

Declared claim: Cyclic coefficient projection; `PROVED`; Paper IV. Symbol: `komorebi_math.analytic.cyclic.cyclic_project_coefficients`.

Declared hypotheses: finite or convergent coefficient sequence. Suite label: `analytic.cyclic`.

Locations: `analytic/cyclic.py:27`, `analytic/cyclic.py:121`. **Direct base sites:** `H-C018`.

`H-C018`: status `Exactness.EXACT`; checked `('finite coefficient vector', 'complete residue family')`; unchecked `()`. Residual keys: `reconstruction`.

Observed examples: `EX-E-011`. **Literal test mentions:** none recorded.

H-T333 / PSC-IV-T05

Declared claim: Transfer exponential section; `PROVED`; Paper IV. Symbol: `komorebi_math.analytic.sections.transfer_section`.

Declared hypotheses: finite order; convergent entire series. Suite label: `analytic.sections`.

Locations: `analytic/sections.py:55`, `analytic/sections.py:224`. **Direct base sites:** `H-C020`.

`H-C020`: status `Exactness.NUMERICAL`; checked `('finite root system', 'entire section series')`; unchecked `()`. Residual keys: `root_sum`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T334 / PSC-IV-T09

Declared claim: Signed cyclic section; PROVED; Paper IV. Symbol: komorebi_math.analytic.sections.signed_section.

Declared hypotheses: finite order; convergent entire series. Suite label: analytic.sections.

Locations: analytic/sections.py:87, analytic/sections.py:224. **Direct base sites:** H-C020.

H-C020: status Exactness.NUMERICAL; checked ('finite root system', 'entire section series'); unchecked (). Residual keys: root_sum.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T335 / PSC-IV-T15

Declared claim: Reciprocal power coefficients; PROVED; Paper IV. Symbol: komorebi_math.analytic.reciprocal.reciprocal_coefficients.

Declared hypotheses: finite cyclic order; declared reciprocal parameter. Suite label: analytic.reciprocal.

Locations: analytic/reciprocal.py:45. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T336 / PSC-IV-T17

Declared claim: Logarithmic reciprocal coefficients; PROVED; Paper IV. Symbol: komorebi_math.analytic.reciprocal.logarithmic_coefficients.

Declared hypotheses: finite cyclic order. Suite label: analytic.reciprocal.

Locations: analytic/reciprocal.py:26. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T337 / PSC-IV-T18

Source symbol(s): komorebi_math.analytic.reciprocal.reciprocal_semigroup_certificate. No attached provenance record under this label.

Locations: analytic/reciprocal.py:150. **Direct base sites:** H-C019.

H-C019: status Exactness.EXACT if exact and maximum == 0 else Exactness.NUMERICAL; checked ('finite reciprocal coefficient system',); unchecked (). Residual keys: maximum_coefficient.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T338 / PSC-IV-T28

Declared claim: Congruential triangular inverse; PROVED; Paper IV. Symbol: komorebi_math.analytic.appell.congruential_inverse.

Declared hypotheses: finite cyclic order; valid residue address. Suite label: analytic.appell.

Locations: analytic/appell.py:42. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T339 / PSC-IV-T54

Declared claim: Large cyclic zero strings; PROVED; Paper IV. Symbol: komorebi_math.analytic.zeros.positive_zero_string.

Declared hypotheses: cyclic order at least two; numerical Newton convergence for requested representatives. **Declared limits:** the executable routine certifies residuals, not the full asymptotic theorem. Suite label: analytic.zeros.

Locations: analytic/zeros.py:85, analytic/zeros.py:127. **Direct base sites:** H-C021.

H-C021: status Exactness.NUMERICAL; checked ('positive asymptotic seeds', 'Newton residuals', 'strict ordering'); unchecked ('exhaustion of every large zero outside the computed range',). Residual keys: maximum_zero_residual.

Observed examples: EX-E-011. **Literal test mentions:** none recorded.

H-T340 / PSC-IV-T68

Source symbol(s): komorebi_math.analytic.zeros.reduced_zero_zeta. No attached provenance record under this label.

Locations: analytic/zeros.py:205, analytic/zeros.py:224. **Direct base sites:** H-C022, H-C023.

H-C022: status Exactness.NUMERICAL; checked ('finite computed zero string',); unchecked ('zeta tail beyond the computed zeros',). Residual keys: maximum_zero_residual. H-C023: status Exactness.CONDITIONAL; checked ('Hurwitz zeta leading model',); unchecked ('entire correction term',). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T341 / PSC-IX-D01

Declared claim: Exact prime valuation; DEFINITION; Paper IX. Symbol: komorebi_math.arithmetic.valuation.padic_valuation.

Declared hypotheses: rational input; prime valuation base. Suite label: arithmetic.valuation.

Locations: arithmetic/valuation.py:37. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T342 / PSC-IX-D02

Declared claim: Finite Hurwitz series; DEFINITION; Paper IX. Symbol: komorebi_math.arithmetic.hurwitz.HurwitzSeries.

Declared hypotheses: finite coefficient truncation. Suite label: arithmetic.hurwitz.

Locations: arithmetic/hurwitz.py:92. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T343 / PSC-IX-P18

Declared claim: Binomial carry valuation; CLASSICAL; Paper IX. Symbol: komorebi_math.arithmetic.valuation.binomial_valuation.

Declared hypotheses: prime valuation base; valid binomial indices. Suite label: arithmetic.valuation.

Locations: arithmetic/valuation.py:86. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T344 / PSC-IX-T03

Declared claim: Finite field subgroup selector; `PROVED`; Paper IX. Symbol: `komorebi_math.arithmetic.hurwitz.subgroup_selector`.

Declared hypotheses: prime field; subgroup order divides prime minus one. Suite label: `arithmetic.hurwitz`.

Locations: `arithmetic/hurwitz.py:204`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T345 / PSC-IX-T09

Declared claim: Uniform standard window period; `PROVED`; Paper IX. Symbol: `komorebi_math.arithmetic.standard_windows.StandardWindow`.

Declared hypotheses: odd prime; compression divides prime minus one; standard address. **Declared limits:** period is proved modulo the residue prime. Suite label: `arithmetic.standard_windows`.

Locations: `arithmetic/standard_windows.py:67`, `arithmetic/standard_windows.py:176`. **Direct base sites:** `H-C035`.

`H-C035`: status `Exactness.EXACT`; checked `('prime field arithmetic', 'standard address', 'compression divides prime minus one')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-054`. **Literal test mentions:** none recorded.

H-T346 / PSC-IX-T19

Declared claim: Unified local Euler transfer; `PROVED`; Paper IX. Symbol: `komorebi_math.arithmetic.euler.EulerLocalCoordinates`.

Declared hypotheses: prime local chart; even Euler index. **Declared limits:** odd and dyadic integral charts remain distinct. Suite label: `arithmetic.euler`.

Locations: `arithmetic/euler.py:139`, `arithmetic/euler.py:272`, `arithmetic/euler.py:304`. **Direct base sites:** `H-C024`, `H-C025`.

`H-C024`: status `Exactness.EXACT`; checked `('prime local chart', 'even Euler index', 'finite exact arithmetic')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal). `H-C025`: status `Exactness.EXACT`; checked `('prime local chart', 'finite exact coefficient range')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-017`, `EX-E-027`. **Literal test mentions:** none recorded.

H-T347 / PSC-IX-T25

Source symbol(s): `komorebi_math.arithmetic.mahler.UnitModeMahler.certificate`. No attached provenance record under this label.

Locations: `arithmetic/mahler.py:356`. **Direct base sites:** `H-C031`.

`H-C031`: status `Exactness.EXACT`; checked `('nonnegative integer evaluation range',)`; unchecked `('a finite truncation is exact beyond its Mahler degree only when omitted terms vanish',) if truncation < nmax else ()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T348 / PSC-IX-T26

Source symbol(s): `komorebi_math.arithmetic.local_modes.simultaneous_unit_difference`. No attached provenance record under this label.

Locations: `arithmetic/local_modes.py:133`. **Direct base sites:** `H-C027`.

`H-C027`: status `Exactness.EXACT`; checked `('base is a unit at every declared prime', 'common Carmichael jump')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T349 / PSC-IX-T28

Declared claim: Finite Mahler reconstruction; `PROVED`; Paper IX. Symbol: `komorebi_math.arithmetic.mahler.MahlerSeries`.

Declared hypotheses: finite consecutive value prefix. Suite label: `arithmetic.mahler`.

Locations: `arithmetic/mahler.py:64`, `arithmetic/mahler.py:161`. **Direct base sites:** `H-C028`.

`H-C028`: status `Exactness.EXACT if exact else Exactness.NUMERICAL`; checked `('finite Mahler polynomial',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

Source symbol(s): `komorebi_math.langlands.finite_image.orbits.MonomialAction.packet_certificate`. No attached provenance record under this label.

Locations: `langlands/finite_image/orbits.py:157`. **Direct base sites:** `H-C184`.

`H-C184`: status `Exactness.EXACT`; checked `('finite monomial basis action', 'orbit stabilizer theorem')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-020`. **Literal test mentions:** none recorded.

H-T358 / PSC-LANG-RAMIFICATION-TOWER

Source symbol(s): `komorebi_math.langlands.ramification.towers.RamificationCliffordTower.report`. No attached provenance record under this label.

Locations: `langlands/ramification/towers.py:143`. **Direct base sites:** `H-C202`.

`H-C202`: status `Exactness.CONDITIONAL`; checked `('finite ramification order chain', 'declared Clifford orbit dimensions')`; unchecked `tuple((f'canonical phase at ramification stage {index}' for index in unresolved))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-044`. **Literal test mentions:** none recorded.

H-T359 / PSC-LANG-SOLVABLE-COMPLETION

Source symbol(s): `komorebi_math.langlands.finite_image.clifford.CliffordTower.automorphic_plan`. No attached provenance record under this label.

Locations: `langlands/finite_image/clifford.py:147`. **Direct base sites:** `H-C181`.

`H-C181`: status `Exactness.CONDITIONAL`; checked `('finite Clifford word', 'cyclic induction steps', 'rank-one extension steps')`; unchecked `tuple(unchecked)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T360 / PSC-SEQ-AUTOMATIC

Source symbol(s): `komorebi_math.sequences.automatic.AutomaticSequence.certificate`. No attached provenance record under this label.

Locations: `sequences/automatic.py:159`. **Direct base sites:** `H-C318`.

`H-C318`: status `Exactness.EXACT`; checked `('finite deterministic transition table', 'numeric output table')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-001`. **Literal test mentions:** none recorded.

H-T361 / PSC-SEQ-HOLONOMIC

Source symbol(s): `komorebi_math.sequences.holonomic.HolonomicRecurrence.certificate`. No attached provenance record under this label.

Locations: `sequences/holonomic.py:139`. **Direct base sites:** `H-C322`.

`H-C322`: status `Exactness.EXACT`; checked `('exact rational polynomial recurrence', 'nonvanishing executed leading coefficients')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-001`. **Literal test mentions:** none recorded.

H-T362 / PSC-V-C37

Source symbol(s): `komorebi_math.signals.recovery.recover_jumps_subgaussian`. No attached provenance record under this label.

Locations: `signals/recovery.py:182`. **Direct base sites:** `H-C343`.

`H-C343`: status `Exactness.CONDITIONAL`; checked `result.certificate.assumptions_checked + ('declared sub Gaussian confidence calculation',)`; unchecked `('sample noises are independent centered sigma sub Gaussian variables',) + result.certificate.assumptions_unchecked[1:]`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T363 / PSC-V-D01

Declared claim: One dimensional polyphase coordinates; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.polyphase.PolyphaseCoordinates`.

Declared hypotheses: finite array; positive packet order. Suite label: `signals.polyphase`.

Locations: `signals/polyphase.py:38`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T364 / PSC-V-D03

Declared claim: Rectangular lattice packet coordinates; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.polyphase.LatticePolyphaseCoordinates`.

Declared hypotheses: finite array; positive stride in every dimension. Suite label: `signals.polyphase`.

Locations: `signals/polyphase.py:294`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T365 / PSC-V-D06

Declared claim: Finite polyphase convolution transfer matrix; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.convolution.PolyphaseConvolution`.

Declared hypotheses: finite convolution matrix; common packet order. Suite label: `signals.convolution`.

Locations: `signals/convolution.py:98`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T366 / PSC-V-D08

Declared claim: Finite periodic filter bank; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.filterbanks.PeriodicFilterBank`.

Declared hypotheses: finite periodic signal; length divisible by decimation. Suite label: `signals.filterbanks`.

Locations: `signals/filterbanks.py:38`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T367 / PSC-V-D12

Declared claim: Finite Haar packet tree; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.wavelets.HaarPacketTree`.

Declared hypotheses: finite signal length divisible by two to the tree depth. Suite label: `signals.wavelets`.

Locations: `signals/wavelets.py:52`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T368 / PSC-V-D15

Declared claim: Truncated power singular packet; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.singular_packets.TruncatedPowerTerm`.

Declared hypotheses: nonnegative derivative order. Suite label: `signals.singular_packets`.

Locations: `signals/singular_packets.py:33`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T369 / PSC-V-D16

Declared claim: Finite one dimensional singular packet; `DEFINITION`; Paper V. Symbol: `komorebi_math.signals.singular_packets.SingularPacket1D`.

Declared hypotheses: finite packet family. Suite label: `signals.singular_packets`.

Locations: `signals/singular_packets.py:108`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T370 / PSC-V-H01

Declared claim: Positive contrast two class packet estimator; `HEURISTIC`; Paper V. Symbol: `komorebi_math.signals.approximation.estimate_positive_packet_1d`.

Declared hypotheses: one dominant positive contrast region. **Declared limits:** not a universal edge detector. Suite label: `signals.approximation`.

Locations: `signals/approximation.py:78`, `signals/approximation.py:104`. **Direct base sites:** `H-C324`.

`H-C324`: status `Exactness.HEURISTIC`; checked `()`; unchecked `('two class positive contrast model', 'topological cleanup is unnecessary')`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T371 / PSC-V-T02

Declared claim: Exact finite polyphase decomposition; `PROVED`; Paper V. Symbol: `komorebi_math.signals.polyphase.polyphase_analyze`.

Declared hypotheses: finite array; positive packet order. Suite label: `signals.polyphase`.

Locations: `signals/polyphase.py:121`, `signals/polyphase.py:157`. **Direct base sites:** `H-C340`.

`H-C340`: status `Exactness.NUMERICAL`; checked `('finite residue partition', 'declared original shape')`; unchecked `()`. Residual keys: `polyphase_reconstruction`.

Observed examples: `EX-E-036`. **Literal test mentions:** none recorded.

H-T372 / PSC-V-T04

Declared claim: Exact rectangular lattice polyphase decomposition; PROVED; Paper V. Symbol: komorebi_math.signals.polyphase.lattice_polyphase_analyze.

Declared hypotheses: finite multidimensional array; positive rectangular strides. Suite label: signals.polyphase.

Locations: signals/polyphase.py:369, signals/polyphase.py:381. **Direct base sites:** H-C341.

H-C341: status Exactness.NUMERICAL; checked ('rectangular lattice residue partition',); unchecked (). Residual keys: lattice_polyphase_reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T373 / PSC-V-T05

Declared claim: Finite convolution matrix; PROVED; Paper V. Symbol: komorebi_math.signals.convolution.convolution_matrix.

Declared hypotheses: finite one dimensional signal; declared boundary mode. Suite label: signals.convolution.

Locations: signals/convolution.py:44. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T374 / PSC-V-T07

Declared claim: Exact finite convolution transfer law; PROVED; Paper V. Symbol: komorebi_math.signals.convolution.PolyphaseConvolution.certificate.

Declared hypotheses: finite convolution; residue packet coordinates. Suite label: signals.convolution.

Locations: signals/convolution.py:182, signals/convolution.py:199. **Direct base sites:** H-C325.

H-C325: status Exactness.NUMERICAL; checked ('finite convolution matrix', 'exact residue partition'); unchecked (). Residual keys: transfer_law.

Observed examples: EX-E-036. **Literal test mentions:** none recorded.

H-T375 / PSC-V-T09

Declared claim: Finite perfect reconstruction criterion; PROVED; Paper V. Symbol: komorebi_math.signals.filterbanks.PeriodicFilterBank.perfect_reconstruction_certificate.

Declared hypotheses: finite periodic bank; matching analysis and synthesis matrices. Suite label: signals.filterbanks.

Locations: signals/filterbanks.py:114, signals/filterbanks.py:132, signals/filterbanks.py:353. **Direct base sites:** H-C332, H-C335.

H-C332: status Exactness.NUMERICAL; checked ('finite periodic convention', 'matching channel count'); unchecked (). Residual keys: reconstruction_operator. H-C335: status Exactness.NUMERICAL; checked ('finite analysis matrix', 'declared synthesis matrix'); unchecked (). Residual keys: reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T376 / PSC-V-T10

Declared claim: Orthonormal Haar reconstruction; PROVED; Paper V. Symbol: komorebi_math.signals.filterbanks.HaarFilterBank.

Declared hypotheses: even finite signal length. Suite label: signals.filterbanks.

Locations: signals/filterbanks.py:161, signals/filterbanks.py:206. **Direct base sites:** H-C333.

H-C333: status Exactness.NUMERICAL; checked ('even finite signal',); unchecked (). Residual keys: reconstruction, energy.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T377 / PSC-V-T11

Declared claim: Exact periodic lifting update; `PROVED`; Paper V. Symbol: `komorebi_math.signals.filterbanks.PeriodicLiftingScheme`.

Declared hypotheses: even finite periodic signal. Suite label: `signals.filterbanks`.

Locations: `signals/filterbanks.py:226`, `signals/filterbanks.py:281`. **Direct base sites:** `H-C334`.

`H-C334`: status `Exactness.NUMERICAL`; checked `('periodic boundary convention', 'even finite signal')`; unchecked `()`. Residual keys: `lifting_roundtrip`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T378 / PSC-V-T13

Declared claim: Exact reconstruction on a pruned Haar packet tree; `PROVED`; Paper V. Symbol: `komorebi_math.signals.wavelets.HaarPacketTree.reconstruct`.

Declared hypotheses: complete finite pruning; Haar local splits. Suite label: `signals.wavelets`.

Locations: `signals/wavelets.py:152`, `signals/wavelets.py:188`. **Direct base sites:** `H-C359`.

`H-C359`: status `Exactness.NUMERICAL`; checked `('complete pruning', 'finite Haar tree')`; unchecked `()`. Residual keys: `reconstruction`, `energy`.

Observed examples: `EX-E-036`. **Literal test mentions:** none recorded.

H-T379 / PSC-V-T14

Declared claim: Exact additive best basis recursion; `PROVED`; Paper V. Symbol: `komorebi_math.signals.wavelets.best_basis`.

Declared hypotheses: finite packet tree; additive node cost. Suite label: `signals.wavelets`.

Locations: `signals/wavelets.py:264`, `signals/wavelets.py:302`. **Direct base sites:** `H-C360`.

`H-C360`: status `Exactness.EXACT`; checked `('finite binary tree', 'additive local costs')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T380 / PSC-V-T17

Declared claim: Exact retained packet reconstruction identity; `PROVED`; Paper V. Symbol: `komorebi_math.signals.singular_packets.retained_packet_reconstruct`.

Declared hypotheses: signal equals smooth component plus retained packet. Suite label: `signals.singular_packets`.

Locations: `signals/singular_packets.py:206`, `signals/singular_packets.py:242`. **Direct base sites:** `H-C348`.

`H-C348`: status `Exactness.NUMERICAL`; checked `('declared packet subtraction', 'shape preserving smooth approximator')`; unchecked `()`. Residual keys: `retained_packet_identity`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T381 / PSC-V-T18

Source symbol(s): `komorebi_math.signals.singular_packets.retained_packet_reconstruction`. No attached provenance record under this label.

Locations: `signals/singular_packets.py:304`. **Direct base sites:** `H-C349`.

`H-C349`: status `Exactness.NUMERICAL`; checked `tuple(assumptions_checked)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-052`. **Literal test mentions:** none recorded.

H-T382 / PSC-V-T19

Declared claim: Deterministic separated jump cell recovery; PROVED; Paper V. Symbol: komorebi_math.signals.edge_recovery.recover_jumps.

Declared hypotheses: one jump in every active sample cell; Lipschitz smooth component; uniform sample noise bound; minimum jump magnitude exceeds twice the background bound. **Declared limits:** does not certify unknown smoothness or unknown minimum jump size from the samples alone. Suite label: signals.edge_recovery.

Locations: signals/edge_recovery.py:54, signals/edge_recovery.py:129. **Direct base sites:** H-C329.

H-C329: status exactness; checked ('positive finite spacing', 'minimum jump exceeds twice the declared background bound' if theorem_separation else 'minimum jump separation failed', 'thr...; unchecked unchecked. Residual keys: background_bound, threshold_lower_margin, threshold_upper_margin.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T383 / PSC-V-T20

Declared claim: Sub Gaussian jump recovery bound; PROVED; Paper V. Symbol: komorebi_math.signals.edge_recovery.recover_jumps_subgaussian.

Declared hypotheses: independent centered sub Gaussian sample noise; one separated jump per active cell; known Lipschitz and minimum jump bounds. Suite label: signals.edge_recovery.

Locations: signals/edge_recovery.py:151, signals/edge_recovery.py:195. **Direct base sites:** H-C330.

H-C330: status Exactness.CONDITIONAL; checked result.certificate.assumptions_checked + (f'declared probability at least {1.0 - delta:.12g}',); unchecked ('sample noise coordinates are independent and centered', f'every coordinate obeys the declared sub Gaussian scale {s.... Residual keys: coordinate_noise_bound, simultaneous_noise_difference_bound.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T384 / PSC-V-T21

Source symbol(s): komorebi_math.signals.singular_packets.scalar_region_error. No attached provenance record under this label.

Locations: signals/singular_packets.py:438. **Direct base sites:** H-C350.

H-C350: status Exactness.NUMERICAL; checked ('finite equal shaped masks',); unchecked (). Residual keys: region_overlap_formula.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T385 / PSC-V-T22

Source symbol(s): komorebi_math.signals.singular_packets.overlap_matrix_error. No attached provenance record under this label.

Locations: signals/singular_packets.py:481. **Direct base sites:** H-C351.

H-C351: status Exactness.NUMERICAL; checked ('finite labeled partitions',); unchecked (). Residual keys: overlap_matrix_formula.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T386 / PSC-V-T36

Declared claim: Stable recovery of separated one dimensional jumps; CONDITIONAL; Paper V. Symbol: komorebi_math.signals.recovery.recover_separated_jumps.

Declared hypotheses: smooth part has the declared Lipschitz bound; sample noise has the declared uniform bound; every jump magnitude is at least the declared minimum; at most one jump lies in each sample cell. **Declared limits:** one dimensional sampled signals; separated value jumps. Suite label: signals.recovery.

Locations: signals/recovery.py:52, signals/recovery.py:117. **Direct base sites:** H-C342.

H-C342: status Exactness.CONDITIONAL; checked ('positive sample spacing', 'valid threshold gap', 'declared minimum separation is at least one cell' if minimum_separation is not None else 'no finite ...; unchecked ('unknown smooth part obeys the declared Lipschitz bound', 'unknown sample noise obeys the declared uniform bound', '.... Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-052. **Literal test mentions:** none recorded.

H-T387 / PSC-V-T43

Source symbol(s): komorebi_math.signals.recovery.detect_piecewise_polynomial_breaks. No attached provenance record under this label.

Locations: signals/recovery.py:253. **Direct base sites:** H-C344.

H-C344: status Exactness.CONDITIONAL; checked ('finite difference order', 'threshold exceeds declared noise amplification'); unchecked ('the noiseless signal is polynomial of the declared degree on every segment', 'sample noise obeys the declared unifo.... Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T388 / PSC-V-T51

Declared claim: Cyclic product packet law; PROVED; Paper V. Symbol: komorebi_math.signals.nonlinear.packet_product.

Declared hypotheses: finite coefficient sequences or explicit residue channels. Suite label: signals.nonlinear.

Locations: signals/nonlinear.py:55, signals/nonlinear.py:112, signals/nonlinear.py:141. **Direct base sites:** H-C338, H-C339.

H-C338: status Exactness.NUMERICAL; checked ('explicit compact residue channels', 'radix carry propagation'); unchecked (). Residual keys: cyclic_channel_law. H-C339: status Exactness.NUMERICAL; checked ('finite Cauchy product',); unchecked (). Residual keys: product_reconstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T389 / PSC-VI-C22

Source symbol(s): komorebi_math.dynamics.markov.FiniteMarkovChain.stationary_distribution. No attached provenance record under this label.

Locations: dynamics/markov.py:225. **Direct base sites:** H-C093.

H-C093: status Exactness.NUMERICAL; checked ('finite Markov operator',); unchecked (). Residual keys: stationarity, mass, negativity.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T390 / PSC-VI-C57

Source symbol(s): komorebi_math.dynamics.feynman_kac.FiniteFeynmanKac.coarse_model. No attached provenance record under this label.

Locations: dynamics/feynman_kac.py:154, dynamics/feynman_kac.py:173. **Direct base sites:** H-C088, H-C089.

H-C088: status Exactness.CONDITIONAL; checked ('finite partition',); unchecked ('exact Markov lumping', 'block constant potential'). Residual keys: lumping, potential_variation. H-C089: status Exactness.NUMERICAL; checked ('exact Markov lumping', 'block constant potential'); unchecked (). Residual keys: lumping, potential_variation.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T391 / PSC-VI-D01

Declared claim: Finite matrix semigroup; `DEFINITION`; Paper VI. Symbol: `komorebi_math.dynamics.semigroups.MatrixSemigroup`.

Declared hypotheses: finite square generator. Suite label: `dynamics.semigroups`.

Locations: `dynamics/semigroups.py:25`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T392 / PSC-VI-D07

Declared claim: Semigroup refinement defect; `DEFINITION`; Paper VI. Symbol: `komorebi_math.dynamics.semigroups.SemigroupRefinement`.

Declared hypotheses: finite fine and coarse generators; linear coarsening map. Suite label: `dynamics.semigroups`.

Locations: `dynamics/semigroups.py:149`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T393 / PSC-VI-D18

Declared claim: Finite Markov operator; `DEFINITION`; Paper VI. Symbol: `komorebi_math.dynamics.markov.FiniteMarkovChain`.

Declared hypotheses: column probability convention. Suite label: `dynamics.markov`.

Locations: `dynamics/markov.py:150`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T394 / PSC-VI-D27

Declared claim: Finite Feshbach decomposition; `DEFINITION`; Paper VI. Symbol: `komorebi_math.dynamics.feshbach.FeshbachReduction`.

Declared hypotheses: finite matrix; declared retained coordinates. Suite label: `dynamics.feshbach`.

Locations: `dynamics/feshbach.py:27`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T395 / PSC-VI-D33

Declared claim: Finite Bayesian update; `DEFINITION`; Paper VI. Symbol: `komorebi_math.dynamics.bayes.BayesianUpdate`.

Declared hypotheses: finite prior; nonnegative likelihood with positive evidence. Suite label: `dynamics.bayes`.

Locations: `dynamics/bayes.py:48`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T396 / PSC-VI-T01

Source symbol(s): `komorebi_math.dynamics.semigroups.MatrixSemigroup.semigroup_certificate`. No attached provenance record under this label.

Locations: `dynamics/semigroups.py:76`. **Direct base sites:** `H-C101`.

`H-C101`: status `Exactness.NUMERICAL`; checked `('finite matrix generator',)`; unchecked `()`. Residual keys: `semigroup_law`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T397 / PSC-VI-T02

Declared claim: Packet semigroup convolution; `PROVED`; Paper VI. Symbol: `komorebi_math.dynamics.semigroups.PacketSemigroup`.

Declared hypotheses: finite complete packet family. Suite label: `dynamics.semigroups`.

Locations: `dynamics/semigroups.py:88`, `dynamics/semigroups.py:128`. **Direct base sites:** `H-C102`.

`H-C102`: status `Exactness.NUMERICAL`; checked `('complete packet family', 'finite semigroup')`; unchecked `()`. Residual keys: `packet_convolution`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T398 / PSC-VI-T08

Source symbol(s): `komorebi_math.dynamics.semigroups.SemigroupRefinement.duhamel`. No attached provenance record under this label.

Locations: `dynamics/semigroups.py:211`. **Direct base sites:** `H-C103`.

`H-C103`: status `Exactness.NUMERICAL`; checked `('finite generators', 'Gauss Legendre quadrature')`; unchecked `()`. Residual keys: `duhamel_identity`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T399 / PSC-VI-T10

Source symbol(s): `komorebi_math.dynamics.semigroups.SemigroupRefinement.resolvent_defect`. No attached provenance record under this label.

Locations: `dynamics/semigroups.py:240`. **Direct base sites:** `H-C104`.

`H-C104`: status `Exactness.NUMERICAL`; checked `('value lies in both resolvent sets',)`; unchecked `()`. Residual keys: `resolvent_identity`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T400 / PSC-VI-T12

Source symbol(s): `komorebi_math.dynamics.semigroups.FiniteSemigroupTower.certificate`. No attached provenance record under this label.

Locations: `dynamics/semigroups.py:300`. **Direct base sites:** `H-C105`.

`H-C105`: status `Exactness.NUMERICAL`; checked `('finite tower dimensions',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T401 / PSC-VI-T17

Declared claim: Finite weighted conditional expectation; PROVED; Paper VI. Symbol: komorebi_math.dynamics.martingales.ConditionalExpectation.

Declared hypotheses: positive finite probability weights; finite partition. Suite label: dynamics.martingales.

Locations: dynamics/martingales.py:26, dynamics/martingales.py:81. **Direct base sites:** H-C095.

H-C095: status Exactness.NUMERICAL; checked ('positive normalized weights', 'finite partition'); unchecked (). Residual keys: idempotence, weighted_self_adjointness.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T402 / PSC-VI-T18

Declared claim: Finite martingale packet tower; PROVED; Paper VI. Symbol: komorebi_math.dynamics.martingales.MartingaleTower.

Declared hypotheses: nested finite partitions; common positive probability weights. Suite label: dynamics.martingales.

Locations: dynamics/martingales.py:103, dynamics/martingales.py:152, dynamics/martingales.py:172. **Direct base sites:** H-C096, H-C097.

H-C096: status Exactness.NUMERICAL; checked ('nested finite partitions', 'positive weights'); unchecked (). Residual keys: energy_decomposition. H-C097: status Exactness.NUMERICAL; checked ('nested partition validation',); unchecked (). Residual keys: tower_law.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T403 / PSC-VI-T21

Declared claim: Exact Markov lumpability criterion; PROVED; Paper VI. Symbol: komorebi_math.dynamics.markov.MarkovLumping.

Declared hypotheses: finite Markov operator; fixed state partition. Suite label: dynamics.markov.

Locations: dynamics/markov.py:283, dynamics/markov.py:381. **Direct base sites:** H-C094.

H-C094: status Exactness.NUMERICAL; checked ('column Markov convention', 'finite partition'); unchecked (). Residual keys: kernel_obstruction, coordinate_residual.

Observed examples: EX-E-030. **Literal test mentions:** none recorded.

H-T404 / PSC-VI-T24

Declared claim: Finite spectral fractional operator; PROVED; Paper VI. Symbol: komorebi_math.dynamics.fractional.fractional_power.

Declared hypotheses: finite positive semidefinite Hermitian operator; positive exponent. Suite label: dynamics.fractional.

Locations: dynamics/fractional.py:30. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T405 / PSC-VI-T25

Declared claim: Exact finite fractional naturality; PROVED; Paper VI. Symbol: komorebi_math.dynamics.fractional.fractional_naturality_certificate.

Declared hypotheses: positive self adjoint fine and coarse operators; exact intertwining. Suite label: dynamics.fractional.

Locations: dynamics/fractional.py:70, dynamics/fractional.py:102. **Direct base sites:** H-C090.

H-C090: status Exactness.NUMERICAL; checked ('finite positive Hermitian operators',); unchecked (). Residual keys: generator_intertwining, fractional_intertwining.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T406 / PSC-VI-T26

Declared claim: Finite fractional defect bound; PROVED; Paper VI. Symbol: komorebi_math.dynamics.fractional.FractionalDefectResult.

Declared hypotheses: exponent strictly between zero and one; common positive spectral gap. Suite label: dynamics.fractional.

Locations: dynamics/fractional.py:114, dynamics/fractional.py:166. **Direct base sites:** H-C091.

H-C091: status Exactness.NUMERICAL; checked ('positive Hermitian operators', 'strict positive common gap', 'zero to one exponent'); unchecked (). Residual keys: actual_defect, theorem_bound, bound_excess.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T407 / PSC-VI-T28

Declared claim: Finite Schur Feshbach resolvent; PROVED; Paper VI. Symbol: komorebi_math.dynamics.feshbach.FeshbachReduction.resolvent_certificate.

Declared hypotheses: full and hidden resolvents exist. Suite label: dynamics.feshbach.

Locations: dynamics/feshbach.py:114, dynamics/feshbach.py:136. **Direct base sites:** H-C086.

H-C086: status Exactness.NUMERICAL; checked ('hidden resolvent exists', 'full resolvent exists'); unchecked (). Residual keys: feshbach_resolvent.

Observed examples: EX-E-018, EX-E-026. **Literal test mentions:** none recorded.

H-T408 / PSC-VI-T29

Declared claim: Finite exact local closure criterion; PROVED; Paper VI. Symbol: komorebi_math.dynamics.feshbach.FeshbachReduction.local_closure_certificate.

Declared hypotheses: finite hidden state space. Suite label: dynamics.feshbach.

Locations: dynamics/feshbach.py:172, dynamics/feshbach.py:185. **Direct base sites:** H-C087.

H-C087: status Exactness.NUMERICAL; checked ('finite hidden dimension', 'Cayley Hamilton moment test'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-018. **Literal test mentions:** none recorded.

H-T409 / PSC-VI-T30

Declared claim: Finite rational memory realization; PROVED; Paper VI. Symbol: komorebi_math.dynamics.memory.MemoryKernel.

Declared hypotheses: finite auxiliary state realization. Suite label: dynamics.memory.

Locations: dynamics/memory.py:32, dynamics/memory.py:118. **Direct base sites:** H-C098.

H-C098: status Exactness.NUMERICAL; checked ('finite auxiliary realization', 'hidden resolvent exists'); unchecked (). Residual keys: laplace_decomposition.

Observed examples: EX-E-018. **Literal test mentions:** none recorded.

H-T410 / PSC-VI-T31

Declared claim: Finite horizon Volterra kernel stability bound; PROVED; Paper VI. Symbol: komorebi_math.dynamics.memory.volterra_trajectory_bound.

Declared hypotheses: finite horizon; declared trajectory and kernel bounds. Suite label: dynamics.memory.

Locations: dynamics/memory.py:241, dynamics/memory.py:261, dynamics/memory.py:275. **Direct base sites:** H-C099, H-C100.

H-C099: status Exactness.NUMERICAL; checked ('finite horizon', 'finite rational memory kernels', 'operator norm exponential and derivative bounds'); unchecked (). Residual keys: quadrature_estimate, quadrature_allowance, separate_exponential_bound. H-C100: status Exactness.CONDITIONAL; checked ('finite horizon', 'trapezoidal operator norm quadrature'); unchecked ('quadrature estimate upper bounds the true kernel integral',). Residual keys: quadrature_estimate.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T411 / PSC-VI-T32

Declared claim: Finite state dependent killing survival model; PROVED; Paper VI. Symbol: komorebi_math.dynamics.survival.PhaseTypeSurvival.

Declared hypotheses: finite transient column subgenerator. Suite label: dynamics.survival.

Locations: dynamics/survival.py:30, dynamics/survival.py:101. **Direct base sites:** H-C106.

H-C106: status Exactness.NUMERICAL; checked ('column transient convention', 'nonnegative off diagonal rates', 'strictly stable transient generator'); unchecked (). Residual keys: negative_off_diagonal, negative_absorption_rate, cause_rate_sum, spectral_abscissa_failure.

Observed examples: EX-E-022. **Literal test mentions:** none recorded.

H-T412 / PSC-VI-T33

Source symbol(s): komorebi_math.dynamics.survival.PhaseTypeSurvival.identities_certificate. No attached provenance record under this label.

Locations: dynamics/survival.py:182. **Direct base sites:** H-C107.

H-C107: status Exactness.NUMERICAL; checked ('finite difference derivative check', 'valid survival model'); unchecked (). Residual keys: density_derivative, cause_sum.

Observed examples: EX-E-022. **Literal test mentions:** none recorded.

H-T413 / PSC-VI-T36

Declared claim: Exact two stage Bayesian coarsening; PROVED; Paper VI. Symbol: komorebi_math.dynamics.bayes.BayesianPartition.coarse_posterior.

Declared hypotheses: finite partition; positive evidence. Suite label: dynamics.bayes.

Locations: dynamics/bayes.py:131, dynamics/bayes.py:152. **Direct base sites:** H-C082.

H-C082: status Exactness.NUMERICAL; checked ('finite partition', 'positive evidence'); unchecked (). Residual keys: two_stage_update.

Observed examples: EX-E-030. **Literal test mentions:** none recorded.

H-T414 / PSC-VI-T41

Source symbol(s): komorebi_math.dynamics.bayes.relative_entropy_decomposition. No attached provenance record under this label.

Locations: dynamics/bayes.py:313. **Direct base sites:** H-C083.

H-C083: status Exactness.NUMERICAL; checked ('finite probability vectors', 'fixed partition'); unchecked (). Residual keys: relative_entropy_decomposition.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T415 / PSC-VI-T46

Source symbol(s): `komorebi_math.dynamics.bayes.HiddenMarkovFilter.coarse_step`. No attached provenance record under this label.

Locations: `dynamics/bayes.py:404`, `dynamics/bayes.py:427`. **Direct base sites:** `H-C084`, `H-C085`.

`H-C084`: status `Exactness.CONDITIONAL`; checked `('finite filter step',)`; unchecked `tuple((condition for condition, satisfied in (('transition is exactly lumpable', exact_markov), ('likelihood is block...` Residual keys: none recorded (computed/default when not literal). `H-C085`: status `Exactness.NUMERICAL`; checked `('exact Markov lumping', 'block constant likelihood')`; unchecked `()`. Residual keys: `coarse_filter`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T416 / PSC-VI-T49

Declared claim: Exact discrete Dirichlet Green reconstruction; `PROVED`; Paper VI. Symbol: `komorebi_math.dynamics.green.DirichletGreen1D`.

Declared hypotheses: uniform one dimensional Dirichlet grid. Suite label: `dynamics.green`.

Locations: `dynamics/green.py:17`, `dynamics/green.py:77`. **Direct base sites:** `H-C092`.

`H-C092`: status `Exactness.NUMERICAL`; checked `('uniform Dirichlet grid',)`; unchecked `()`. Residual keys: `inverse_identity`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T417 / PSC-VI-T55

Declared claim: Finite state Feynman Kac transfer; `PROVED`; Paper VI. Symbol: `komorebi_math.dynamics.feynman_kac.FiniteFeynmanKac`.

Declared hypotheses: finite column Markov model; nonnegative killing potential. Suite label: `dynamics.feynman_kac`.

Locations: `dynamics/feynman_kac.py:41`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T418 / PSC-VII-C03

Declared claim: Local orbit and Schmidt rank; `PROVED`; Paper VII. Symbol: `komorebi_math.quantum.seeds.local_orbit_dimension`.

Declared hypotheses: finite bipartite pure state. Suite label: `quantum.seeds`.

Locations: `quantum/seeds.py:67`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T419 / PSC-VII-C17

Source symbol(s): `komorebi_math.quantum.circuits.CircuitPacketExpansion.interference`. No attached provenance record under this label.

Locations: `quantum/circuits.py:161`. **Direct base sites:** `H-C278`.

`H-C278`: status `Exactness.NUMERICAL`; checked `('source packet projection', 'coherent path amplitudes')`; unchecked `()`. Residual keys: `interference_identity`.

Observed examples: `EX-E-042`. **Literal test mentions:** none recorded.

H-T420 / PSC-VII-D59

Declared claim: Finite spectral dimension diagnostic; `DEFINITION`; Paper VII. Symbol: `komorebi_math.quantum.spectral.spectral_dimension`.

Declared hypotheses: finite nonnegative Hermitian operator; positive diffusion time. **Declared limits:** finite dimension forces zero limits at both time endpoints. Suite label: `quantum.spectral`.

Current-source correction. The large-time statement in the historical declaration above is too broad. The limit is zero when the nonnegative operator has a zero eigenvalue. For a positive-definite operator, the diagnostic instead grows asymptotically linearly with time. The zero-time limit remains zero. Section 53.3 gives the corrected interpretation, consistent with the current source at commit `5f2b7ddc879c12d2bb00cbe5c487aa0bc7709222`.

Locations: `quantum/spectral.py:61`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T421 / PSC-VII-P49

Source symbol(s): `komorebi_math.quantum.effective.QuantumFeshbachReduction.upper_half_plane_sign_certificate`. No attached provenance record under this label.

Locations: `quantum/effective.py:64`. **Direct base sites:** `H-C281`.

`H-C281`: status `Exactness.NUMERICAL`; checked `('Hermitian hidden Hamiltonian', 'upper half plane spectral parameter')`; unchecked `()`. Residual keys: `positive_imaginary_part`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T422 / PSC-VII-T01

Declared claim: Finite quantum seed orbit; `PROVED`; Paper VII. Symbol: `komorebi_math.quantum.seeds.QuantumSeedSystem`.

Declared hypotheses: finite observable family; finite state vector. Suite label: `quantum.seeds`.

Locations: `quantum/seeds.py:18`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T423 / PSC-VII-T04

Source symbol(s): `komorebi_math.quantum.seeds.computational_basis_generation`. No attached provenance record under this label.

Locations: `quantum/seeds.py:150`. **Direct base sites:** `H-C291`.

`H-C291`: status `Exactness.NUMERICAL`; checked `('Pauli X address family',)`; unchecked `()`. Residual keys: `basis_orthogonality`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T424 / PSC-VII-T08

Declared claim: Finite group isotypic projector; `CLASSICAL`; Paper VII. Symbol: `komorebi_math.quantum.symmetry.finite_group_projector`.

Declared hypotheses: finite unitary representation; irreducible character values. Suite label: `quantum.symmetry`.

Locations: `quantum/symmetry.py:20`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T425 / PSC-VII-T09

Declared claim: Cyclic character projectors; `PROVED`; Paper VII. Symbol: `komorebi_math.quantum.symmetry.cyclic_symmetry_projectors`.

Declared hypotheses: unitary symmetry of finite order. Suite label: `quantum.symmetry`.

Locations: `quantum/symmetry.py:49`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T426 / PSC-VII-T11

Source symbol(s): `komorebi_math.quantum.symmetry.charge_certificate`, `komorebi_math.quantum.symmetry.charge_selection_certificate`. No attached provenance record under this label.

Locations: `quantum/symmetry.py:106`, `quantum/symmetry.py:137`. **Direct base sites:** `H-C292`, `H-C293`.

`H-C292`: status `Exactness.NUMERICAL`; checked `('unitary cyclic symmetry',)`; unchecked `()`. Residual keys: `charge_relation`. `H-C293`: status `Exactness.NUMERICAL`; checked `('complete cyclic packet family',)`; unchecked `()`. Residual keys: `forbidden_block`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T427 / PSC-VII-T14

Declared claim: Circuit packet path expansion; `PROVED`; Paper VII. Symbol: `komorebi_math.quantum.circuits.CircuitPacketExpansion`.

Declared hypotheses: finite unitary circuit; complete packet system at every circuit depth. Suite label: `quantum.circuits`.

Locations: `quantum/circuits.py:38`, `quantum/circuits.py:129`. **Direct base sites:** `H-C277`.

`H-C277`: status `Exactness.NUMERICAL`; checked `('complete packet resolutions', 'unitary circuit gates')`; unchecked `()`. Residual keys: `circuit_reconstruction`.

Observed examples: `EX-E-042`. **Literal test mentions:** none recorded.

H-T428 / PSC-VII-T15

Source symbol(s): `komorebi_math.quantum.circuits.CircuitPacketExpansion.block_unitarity_certificate`. No attached provenance record under this label.

Locations: `quantum/circuits.py:188`. **Direct base sites:** `H-C279`.

`H-C279`: status `Exactness.NUMERICAL`; checked `('unitary circuit', 'complete source and target packets')`; unchecked `()`. Residual keys: `column_unitarity`.

Observed examples: `EX-E-042`. **Literal test mentions:** none recorded.

H-T429 / PSC-VII-T18

Declared claim: Fixed packet leakage bound; PROVED; Paper VII. Symbol: komorebi_math.quantum.leakage.fixed_packet_leakage.

Declared hypotheses: finite Hermitian Hamiltonian; orthogonal packet projector. Suite label: quantum.leakage.

Locations: quantum/leakage.py:29, quantum/leakage.py:63. **Direct base sites:** H-C287.

H-C287: status Exactness.NUMERICAL; checked ('Hermitian Hamiltonian', 'orthogonal packet projector'); unchecked (). Residual keys: bound_violation.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T430 / PSC-VII-T22

Source symbol(s): komorebi_math.quantum.leakage.moving_packet_leakage_bound. No attached provenance record under this label.

Locations: quantum/leakage.py:124. **Direct base sites:** H-C288.

H-C288: status Exactness.NUMERICAL; checked ('sampled moving geometric coupling',); unchecked ('quadrature error between samples',). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T431 / PSC-VII-T31

Declared claim: Finite Kraus representation; CLASSICAL; Paper VII. Symbol: komorebi_math.quantum.channels.QuantumChannel.

Declared hypotheses: finite Kraus family. Suite label: quantum.channels.

Locations: quantum/channels.py:62, quantum/channels.py:138. **Direct base sites:** H-C275.

H-C275: status Exactness.NUMERICAL; checked ('finite Kraus representation',); unchecked (). Residual keys: trace_preservation, negative_choi_part.

Observed examples: EX-E-041. **Literal test mentions:** none recorded.

H-T432 / PSC-VII-T35

Source symbol(s): komorebi_math.quantum.channels.QuantumChannel.covariance_certificate. No attached provenance record under this label.

Locations: quantum/channels.py:240. **Direct base sites:** H-C276.

H-C276: status Exactness.NUMERICAL; checked ('unitary input and output symmetries',); unchecked (). Residual keys: covariance.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T433 / PSC-VII-T37

Source symbol(s): komorebi_math.quantum.lindblad.LindbladGenerator.trace_preservation_certificate. No attached provenance record under this label.

Locations: quantum/lindblad.py:84. **Direct base sites:** H-C289.

H-C289: status Exactness.NUMERICAL; checked ('finite Lindblad form',); unchecked (). Residual keys: trace_derivative.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T434 / PSC-VII-T38

Declared claim: Lindblad coherence packet preservation; `PROVED`; Paper VII. Symbol: `komorebi_math.quantum.lindblad.LindbladGenerator`.

Declared hypotheses: finite Lindblad generator; cyclic Hamiltonian symmetry; charged jump operators. Suite label: `quantum.lindblad`.

Locations: `quantum/lindblad.py:17`, `quantum/lindblad.py:110`. **Direct base sites:** `H-C290`.

`H-C290`: status `Exactness.NUMERICAL`; checked `('finite cyclic symmetry',)`; unchecked `()`. Residual keys: `coherence_commutator`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T435 / PSC-VII-T42

Declared claim: Knill Laflamme compression criterion; `CLASSICAL`; Paper VII. Symbol: `komorebi_math.quantum.error_correction.QuantumCode`.

Declared hypotheses: finite orthogonal code projector; finite error family. Suite label: `quantum.error_correction`.

Locations: `quantum/error_correction.py:28`, `quantum/error_correction.py:74`. **Direct base sites:** `H-C283`.

`H-C283`: status `Exactness.NUMERICAL`; checked `('orthogonal code projector', 'finite error family')`; unchecked `()`. Residual keys: `compression_obstruction`.

Observed examples: `EX-E-041`. **Literal test mentions:** none recorded.

H-T436 / PSC-VII-T44

Source symbol(s): `komorebi_math.quantum.error_correction.QuantumCode.recovered_channel_certificate`. No attached provenance record under this label.

Locations: `quantum/error_correction.py:123`, `quantum/error_correction.py:141`. **Direct base sites:** `H-C284`, `H-C285`.

`H-C284`: status `Exactness.NUMERICAL`; checked `('Knill Laflamme compression',)`; unchecked `('equal weight error family is trace preserving',)`. Residual keys: `noise_trace_preservation`. `H-C285`: status `Exactness.NUMERICAL`; checked `('Knill Laflamme compression', 'equal weight error channel')`; unchecked `()`. Residual keys: `recovered_code_matrix_units`.

Observed examples: `EX-E-041`. **Literal test mentions:** none recorded.

H-T437 / PSC-VII-T47

Declared claim: Quantum Feshbach reduction; `PROVED`; Paper VII. Symbol: `komorebi_math.quantum.effective.QuantumFeshbachReduction`.

Declared hypotheses: finite Hermitian Hamiltonian; declared retained sector. Suite label: `quantum.effective`.

Locations: `quantum/effective.py:17`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T438 / PSC-VII-T53

Source symbol(s): `komorebi_math.quantum.effective.QuantumFeshbachReduction.bare_closure_certificate`. No attached provenance record under this label.

Locations: `quantum/effective.py:87`. **Direct base sites:** `H-C282`.

`H-C282`: status `Exactness.NUMERICAL`; checked `('finite Hermitian block decomposition',)`; unchecked `()`. Residual keys: `retained_hidden_coupling`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T439 / PSC-VII-T56

Declared claim: Finite reflection positive transfer; PROVED; Paper VII. Symbol: komorebi_math.quantum.euclidean.EuclideanTransfer.

Declared hypotheses: finite nonnegative Hamiltonian after ground shift. Suite label: quantum.euclidean.

Locations: quantum/euclidean.py:18, quantum/euclidean.py:98. **Direct base sites:** H-C286.

H-C286: status Exactness.NUMERICAL; checked ('positive Euclidean transfer operator',); unchecked (). Residual keys: negative_eigenvalue.

Observed examples: EX-E-013. **Literal test mentions:** none recorded.

H-T440 / PSC-VII-T64

Declared claim: Constraint quotient obstruction; PROVED; Paper VII. Symbol: komorebi_math.quantum.constraints.constraint_closure.

Declared hypotheses: finite declared constraint span. Suite label: quantum.constraints.

Locations: quantum/constraints.py:27, quantum/constraints.py:67. **Direct base sites:** H-C280.

H-C280: status Exactness.NUMERICAL; checked ('finite complex linear constraint span',); unchecked (). Residual keys: closure_obstruction.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T441 / PSC-VII-T70

Source symbol(s): komorebi_math.quantum.towers.BoundedHamiltonianTower.report. No attached provenance record under this label.

Locations: quantum/towers.py:61. **Direct base sites:** H-C294.

H-C294: status Exactness.NUMERICAL; checked ('finite bounded Hermitian tower',); unchecked ('infinite tail summability beyond supplied levels',). Residual keys: unitary_bound_violation.

Observed examples: EX-E-013. **Literal test mentions:** none recorded.

H-T442 / PSC-VIII-C01

Source symbol(s): komorebi_math.algorithms.gpu.NumpyPacketExecutor.apply. No attached provenance record under this label.

Locations: algorithms/gpu.py:41. **Direct base sites:** H-C005.

H-C005: status Exactness.NUMERICAL; checked ('NumPy packet execution',); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T443 / PSC-VIII-C02

Source symbol(s): komorebi_math.algorithms.gpu.CupyPacketExecutor.apply. No attached provenance record under this label.

Locations: algorithms/gpu.py:99. **Direct base sites:** H-C006.

H-C006: status Exactness.NUMERICAL; checked ('CuPy installed', 'packet blocks transferred to device'); unchecked ('device execution has not been synchronized for timing',). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T444 / PSC-VIII-D01

Declared claim: Finite packet layout; `DEFINITION`; Paper VIII. Symbol: `komorebi_math.algorithms.layout.PacketLayout`.

Declared hypotheses: positive finite packet sizes. Suite label: `algorithms.layout`.

Locations: `algorithms/layout.py:16`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T445 / PSC-VIII-D02

Declared claim: Dense operator contract; `DEFINITION`; Paper VIII. Symbol: `komorebi_math.algorithms.structured.DenseOperator`.

Declared hypotheses: finite matrix. Suite label: `algorithms.structured`.

Locations: `algorithms/structured.py:78`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T446 / PSC-VIII-H01

Declared claim: Threshold packet support discovery; `HEURISTIC`; Paper VIII. Symbol: `komorebi_math.algorithms.discovery.discover_packet_support`.

Declared hypotheses: fixed packet layout; declared norm threshold. **Declared limits:** a thresholded zero is not an exact algebraic zero. Suite label: `algorithms.discovery`.

Locations: `algorithms/discovery.py:30`, `algorithms/discovery.py:81`. **Direct base sites:** `H-C003`.

`H-C003`: status `Exactness.HEURISTIC`; checked `('fixed packet layout', 'declared threshold')`; unchecked `('discarded blocks are mathematically zero or negligible for the application',)`. Residual keys: `discarded_spectral_norm`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T447 / PSC-VIII-T01

Declared claim: Exact packet operator intermediate representation; `PROVED`; Paper VIII. Symbol: `komorebi_math.algorithms.ir.PacketIR`.

Declared hypotheses: finite source and target packet layouts; declared block dimensions. Suite label: `algorithms.ir`.

Locations: `algorithms/ir.py:22`, `algorithms/ir.py:259`. **Direct base sites:** `H-C007`.

`H-C007`: status `Exactness.NUMERICAL`; checked `('block dimensions', 'packet address ranges')`; unchecked `()`. Residual keys: `apply_materialize`.

Observed examples: `EX-E-035`. **Literal test mentions:** none recorded.

H-T448 / PSC-VIII-T03

Declared claim: Block diagonal packet operator; `PROVED`; Paper VIII. Symbol: `komorebi_math.algorithms.structured.BlockDiagonalOperator`.

Declared hypotheses: finite square packet blocks. Suite label: `algorithms.structured`.

Locations: `algorithms/structured.py:219`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T449 / PSC-VIII-T04

Declared claim: Packet apply arithmetic count; `PROVED`; Paper VIII. Symbol: `komorebi_math.algorithms.complexity.packet_apply_flops`.

Declared hypotheses: dense active packet blocks; classical matrix multiplication count. Suite label: `algorithms.complexity`.

Locations: `algorithms/complexity.py:46`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T450 / PSC-VIII-T07

Declared claim: Kronecker modewise application; `PROVED`; Paper VIII. Symbol: `komorebi_math.algorithms.structured.KroneckerOperator`.

Declared hypotheses: two finite matrix factors. Suite label: `algorithms.structured`.

Locations: `algorithms/structured.py:412`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T451 / PSC-VIII-T10

Declared claim: Block diagonal plus low rank algebra; `PROVED`; Paper VIII. Symbol: `komorebi_math.algorithms.low_rank.BlockDiagonalLowRankOperator`.

Declared hypotheses: finite square block diagonal part; finite low rank correction. Suite label: `algorithms.low_rank`.

Locations: `algorithms/low_rank.py:214`. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T452 / PSC-VIII-T12

Declared claim: Optimal small core recompression; `PROVED`; Paper VIII. Symbol: `komorebi_math.algorithms.low_rank.recompress_core`.

Declared hypotheses: finite factor matrices; rank constrained spectral or Frobenius approximation. Suite label: `algorithms.low_rank`.

Locations: `algorithms/low_rank.py:98`, `algorithms/low_rank.py:137`, `algorithms/low_rank.py:166`. **Direct base sites:** `H-C014`, `H-C015`.

`H-C014`: status `Exactness.NUMERICAL`; checked `('empty low rank correction',)`; unchecked `()`. Residual keys: `spectral_error`, `frobenius_error`. `H-C015`: status `Exactness.NUMERICAL`; checked `('reduced QR', 'small core singular value decomposition')`; unchecked `()`. Residual keys: `actual_spectral_error`, `certified_spectral_error`, `certified_frobenius_error`.

Observed examples: `EX-E-028`. **Literal test mentions:** none recorded.

H-T453 / PSC-VIII-T13

Declared claim: Optimal fixed layout block diagonal plus low rank approximation; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.discovery.discover_block_diagonal_low_rank.

Declared hypotheses: fixed packet layout; rank constrained approximation of the off diagonal residual. Suite label: algorithms.discovery.

Locations: algorithms/discovery.py:107, algorithms/discovery.py:149. **Direct base sites:** H-C004.

H-C004: status Exactness.NUMERICAL; checked ('fixed packet diagonal projection', 'singular value truncation of residual'); unchecked (). Residual keys: actual_spectral_error, optimal_spectral_error, optimal_frobenius_error.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T454 / PSC-VIII-T15

Declared claim: Packet support multiplication; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.support.support_product.

Declared hypotheses: finite packet support relations. Suite label: algorithms.support.

Locations: algorithms/support.py:48. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T455 / PSC-VIII-T18

Declared claim: Schur complement fill support; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.support.schur_fill_support.

Declared hypotheses: finite retained and hidden packet partition. **Declared limits:** support is an inclusion because algebraic cancellation may remove permitted blocks. Suite label: algorithms.support.

Locations: algorithms/support.py:146. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T456 / PSC-VIII-T20

Declared claim: Finite Krylov packet decomposition; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.krylov.krylov_basis.

Declared hypotheses: finite linear operator; declared start vector. Suite label: algorithms.krylov.

Locations: algorithms/krylov.py:32, algorithms/krylov.py:75. **Direct base sites:** H-C008.

H-C008: status Exactness.NUMERICAL; checked ('finite dimension', 'modified Gram Schmidt'); unchecked (). Residual keys: orthogonality.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T457 / PSC-VIII-T22

Declared claim: Preconditioned conjugate gradient certificate; CLASSICAL; Paper VIII. Symbol: komorebi_math.algorithms.krylov.conjugate_gradient.

Declared hypotheses: Hermitian positive definite operator; positive definite preconditioner. Suite label: algorithms.krylov.

Locations: algorithms/krylov.py:100, algorithms/krylov.py:183, algorithms/krylov.py:259. **Direct base sites:** H-C009, H-C010.

H-C009: status Exactness.NUMERICAL; checked ('initial residual tolerance',); unchecked (). Residual keys: final_residual. H-C010: status Exactness.NUMERICAL; checked ('positive curvature on generated directions',); unchecked ('global Hermitian positive definiteness',). Residual keys: final_residual, recursive_final_residual.

Observed examples: EX-E-055. **Literal test mentions:** none recorded.

H-T458 / PSC-VIII-T23

Source symbol(s): komorebi_math.algorithms.krylov.lanczos_tridiagonal. No attached provenance record under this label.

Locations: algorithms/krylov.py:362. **Direct base sites:** H-C011.

H-C011: status Exactness.NUMERICAL; checked ('Hermitian behavior on generated basis', 'full reorthogonalization'); unchecked ('global Hermitian operator',). Residual keys: orthogonality, projected_tridiagonal.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T459 / PSC-VIII-T24

Declared claim: Packet block Jacobi condition bound; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.krylov.block_jacobi_certificate.

Declared hypotheses: Hermitian positive definite packet diagonal; normalized coupling norm below one. Suite label: algorithms.krylov.

Locations: algorithms/krylov.py:407, algorithms/krylov.py:456. **Direct base sites:** H-C012.

H-C012: status Exactness.NUMERICAL; checked ('Hermitian matrix', 'positive definite packet diagonal'); unchecked () if eta < 1 else ('normalized coupling norm below one',). Residual keys: hermitian, normalized_coupling, actual_preconditioned_condition.

Observed examples: EX-E-055. **Literal test mentions:** none recorded.

H-T460 / PSC-VIII-T25

Source symbol(s): komorebi_math.algorithms.precision.precision_certificate. No attached provenance record under this label.

Locations: algorithms/precision.py:269. **Direct base sites:** H-C017.

H-C017: status Exactness.NUMERICAL; checked ('packetwise operator perturbation norms', 'source packet norms'); unchecked (). Residual keys: observed_error, certified_bound.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T461 / PSC-VIII-T26

Declared claim: Continuous packet precision allocation; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.precision.optimal_precision_tolerances.

Declared hypotheses: positive sensitivities; positive logarithmic costs; positive error budget. Suite label: algorithms.precision.

Locations: algorithms/precision.py:37. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T462 / PSC-VIII-T28

Declared claim: Exact discrete precision assignment; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.precision.assign_discrete_precisions.

Declared hypotheses: finite option list for every packet; integer error budget. Suite label: algorithms.precision.

Locations: algorithms/precision.py:158, algorithms/precision.py:201. **Direct base sites:** H-C016.

H-C016: status Exactness.EXACT; checked ('finite option lists', 'integer additive error model'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-038. **Literal test mentions:** none recorded.

H-T463 / PSC-VIII-T30

Declared claim: Exact additive tree compiler; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.compiler.compile_tree_lagrangian.

Declared hypotheses: finite rooted tree; additive keep and split models. Suite label: algorithms.compiler.

Locations: algorithms/compiler.py:76, algorithms/compiler.py:119. **Direct base sites:** H-C001.

H-C001: status Exactness.EXACT; checked ('finite tree', 'additive Lagrangian objective'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-034. **Literal test mentions:** none recorded.

H-T464 / PSC-VIII-T33

Declared claim: Exact quantized budget compiler; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.compiler.compile_tree_budget.

Declared hypotheses: finite rooted tree; integer quantized additive error budget. Suite label: algorithms.compiler.

Locations: algorithms/compiler.py:131, algorithms/compiler.py:231. **Direct base sites:** H-C002.

H-C002: status Exactness.EXACT; checked ('finite tree', 'quantized additive error model'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: EX-E-034. **Literal test mentions:** none recorded.

H-T465 / PSC-VIII-T38

Declared claim: Unlimited concurrency task graph schedule; PROVED; Paper VIII. Symbol: komorebi_math.algorithms.scheduling.schedule_unlimited.

Declared hypotheses: finite acyclic task graph; declared task durations; unlimited concurrency. Suite label: algorithms.scheduling.

Locations: algorithms/scheduling.py:64. **Direct base sites:** none recorded.

Certificate fields: no direct literal-ID base constructor is assigned by this static link. Helper-selected IDs and caller-supplied labels are traced through their declarations and the observation ledger; do not infer a per-ID field contract from spelling alone.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T466 / PSC-X-COCHAIN-COMPLEX

Source symbol(s): komorebi_math.deformation.complexes.FiniteCochainComplex.certificate. No attached provenance record under this label.

Locations: deformation/complexes.py:139. **Direct base sites:** H-C078.

H-C078: status Exactness.EXACT; checked ('prime field', 'finite bounded complex', 'successive differentials'); unchecked (). Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T467 / PSC-X-FINITE-OCCUPANCY

Source symbol(s): `komorebi_math.deformation.support.nested_subspace_occupancy`. No attached provenance record under this label.

Locations: `deformation/support.py:222`. **Direct base sites:** `H-C081`.

`H-C081`: status `Exactness.NUMERICAL`; checked `('finite-dimensional column spaces', 'numerical principal-angle intersection')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-012`. **Literal test mentions:** none recorded.

H-T468 / PSC-X-FITTING-SUPPORT

Source symbol(s): `komorebi_math.deformation.support.PresentedModule.fiber`. No attached provenance record under this label.

Locations: `deformation/support.py:145`. **Direct base sites:** `H-C080`.

`H-C080`: status `exactness`; checked `assumptions + ('zeroth Fitting minors',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T469 / PSC-X-FROBENIUS-SEPARATOR

Source symbol(s): `komorebi_math.deformation.companions.finite_frobenius_separator`. No attached provenance record under this label.

Locations: `deformation/companions.py:230`. **Direct base sites:** `H-C077`.

`H-C077`: status `Exactness.EXACT`; checked `('finite supplied Frobenius trace table', 'exact column rank')`; unchecked `('Chebotarev density beyond the supplied table',)`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-023`. **Literal test mentions:** none recorded.

H-T470 / PSC-X-LIFT-FOREST

Source symbol(s): `komorebi_math.deformation.forests.FiniteLiftForest.report`. No attached provenance record under this label.

Locations: `deformation/forests.py:182`. **Direct base sites:** `H-C079`.

`H-C079`: status `Exactness.EXACT`; checked `('finite consecutive levels', 'compatible reduction maps', 'finite stable core calculation')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-012`. **Literal test mentions:** none recorded.

H-T471 / PSC-XI-GAUSS

Source symbol(s): `komorebi_math.langlands.local.gauss.gauss_sum`. No attached provenance record under this label.

Locations: `langlands/local/gauss.py:67`. **Direct base sites:** `H-C192`.

`H-C192`: status `Exactness.NUMERICAL`; checked `('explicit finite field', 'nontrivial additive character')`; unchecked `()`. Residual keys: `magnitude`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T472 / PSC-XI-HEISENBERG-LAW

Source symbol(s): `komorebi_math.langlands.local.heisenberg.HeisenbergModel.group_law_certificate`. No attached provenance record under this label.

Locations: `langlands/local/heisenberg.py:115`. **Direct base sites:** `H-C193`.

`H-C193`: status `Exactness.NUMERICAL`; checked `('finite Schrödinger representation',)`; unchecked `()`. Residual keys: `group_law`.

Observed examples: `EX-E-056`. **Literal test mentions:** none recorded.

H-T473 / PSC-XI-HEISENBERG-TRACE

Source symbol(s): `komorebi_math.langlands.local.heisenberg.HeisenbergModel.trace_support_certificate`. No attached provenance record under this label.

Locations: `langlands/local/heisenberg.py:139`. **Direct base sites:** `H-C194`.

`H-C194`: status `Exactness.NUMERICAL`; checked `('finite exhaustive phase space',)`; unchecked `()`. Residual keys: `off_center_trace`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T474 / PSC-XI-ISOTROPIC-SELECTOR

Source symbol(s): `komorebi_math.langlands.local.heisenberg.HeisenbergModel.selector_certificate`. No attached provenance record under this label.

Locations: `langlands/local/heisenberg.py:163`. **Direct base sites:** `H-C195`.

`H-C195`: status `Exactness.NUMERICAL`; checked `('standard translation Lagrangian',)`; unchecked `()`. Residual keys: `idempotence`, `self_adjoint`.

Observed examples: `EX-E-056`. **Literal test mentions:** none recorded.

H-T475 / PSC-XI-MONODROMY

Source symbol(s): `komorebi_math.langlands.local.tame.SpecialMonodromyBlock.certificate`. No attached provenance record under this label.

Locations: `langlands/local/tame.py:259`. **Direct base sites:** `H-C201`.

`H-C201`: status `Exactness.NUMERICAL`; checked `('finite monodromy chain',)`; unchecked `()`. Residual keys: `monodromy_relation`, `nilpotence`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T476 / PSC-XI-PROJECTIVE-ENVELOPE

Source symbol(s): `komorebi_math.langlands.local.envelopes.ProjectiveIntertwinerEnvelope.recover`. No attached provenance record under this label.

Locations: `langlands/local/envelopes.py:91`. **Direct base sites:** `H-C191`.

`H-C191`: status `Exactness.NUMERICAL`; checked `('projective basis intertwiners', 'scalar commutators')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T477 / PSC-XI-QUADRATIC-REFINEMENT

Source symbol(s): `komorebi_math.langlands.local.symplectic.QuadraticRefinement.polar_certificate`. No attached provenance record under this label.

Locations: `langlands/local/symplectic.py:143`. **Direct base sites:** `H-C197`.

`H-C197`: status `Exactness.EXACT`; checked `('finite exhaustive dyadic vectors',)`; unchecked `()`. Residual keys: `polar_mismatch`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T478 / PSC-XI-RESTRICTED-BRIDGE

Source symbol(s): `komorebi_math.langlands.local.bridge.SymplecticBridge.construct`. No attached provenance record under this label.

Locations: `langlands/local/bridge.py:50`. **Direct base sites:** `H-C190`.

`H-C190`: status `Exactness.EXACT`; checked `('finite prime field symplectic forms',)`; unchecked `()`. Residual keys: `symplectic_mismatch`.

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T479 / PSC-XI-SYMPLECTIC-ENVELOPE

Source symbol(s): `komorebi_math.langlands.local.symplectic.AlternatingForm.certificate`. No attached provenance record under this label.

Locations: `langlands/local/symplectic.py:92`. **Direct base sites:** `H-C196`.

`H-C196`: status `Exactness.EXACT`; checked `('prime field', 'alternating matrix')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T480 / PSC-XI-TAME-ATOM

Source symbol(s): `komorebi_math.langlands.local.tame.TameWeilPacket.relation_certificate`. No attached provenance record under this label.

Locations: `langlands/local/tame.py:178`. **Direct base sites:** `H-C199`.

`H-C199`: status `Exactness.NUMERICAL`; checked `('regular tame orbit', 'declared Frobenius cycle')`; unchecked `()`. Residual keys: `tame_conjugacy`.

Observed examples: `EX-E-056`. **Literal test mentions:** none recorded.

H-T481 / PSC-XI-TAME-ORBIT

Source symbol(s): `komorebi_math.langlands.local.tame.FrobeniusOrbit.certificate`. No attached provenance record under this label.

Locations: `langlands/local/tame.py:109`. **Direct base sites:** `H-C198`.

`H-C198`: status `Exactness.EXACT`; checked `('finite exponent orbit',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-056`. **Literal test mentions:** none recorded.

H-T482 / PSC-XI-TAME-TENSOR

Source symbol(s): `komorebi_math.langlands.local.tame.tame_tensor_refinement`. No attached provenance record under this label.

Locations: `langlands/local/tame.py:212`. **Direct base sites:** `H-C200`.

`H-C200`: status `Exactness.EXACT`; checked `('two cyclic Frobenius orbits',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T483 / PSC-XII-DYADIC-SIGN

Source symbol(s): `komorebi_math.langlands.global_.dyadic.dyadic_sign_diagnostic`. No attached provenance record under this label.

Locations: `langlands/global_/dyadic.py:32`. **Direct base sites:** `H-C186`.

`H-C186`: status `Exactness.EXACT`; checked `('group algebra of C2 over F2',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T484 / PSC-XII-FIVE-GATE-COMPLETION

Source symbol(s): `komorebi_math.langlands.completion.gates.AutomorphicCompletionReport.result`. No attached provenance record under this label.

Locations: `langlands/completion/gates.py:69`. **Direct base sites:** `H-C177`.

`H-C177`: status `Exactness.CONDITIONAL`; checked `checked`; unchecked `unchecked`. Residual keys: none recorded (computed/default when not literal).

Observed examples: `EX-E-044`. **Literal test mentions:** none recorded.

H-T485 / PSC-XII-HECKE-PACKETS

Source symbol(s): `komorebi_math.langlands.global_.hecke.FiniteHeckePackets.certificate`. No attached provenance record under this label.

Locations: `langlands/global_/hecke.py:87`. **Direct base sites:** `H-C187`.

`H-C187`: status `Exactness.NUMERICAL`; checked `('finite central idempotents', 'complete orthogonal decomposition')`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T486 / PSC-XII-ONE-MEMBER-PROPAGATION

Source symbol(s): `komorebi_math.langlands.completion.gates.CompatiblePropagationReport.result`. No attached provenance record under this label.

Locations: `langlands/completion/gates.py:103`. **Direct base sites:** `H-C178`.

`H-C178`: status `Exactness.CONDITIONAL`; checked `tuple((name for name, value in values.items() if value))`; unchecked `tuple((name for name, value in values.items() if not value))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T487 / PSC-XII-PATCHING-SUPPORT

Source symbol(s): `komorebi_math.langlands.global_.patching.PatchingSupportReport.certificate`. No attached provenance record under this label.

Locations: `langlands/global_/patching.py:58`. **Direct base sites:** `H-C189`.

`H-C189`: status `Exactness.CONDITIONAL`; checked `tuple((label for value, label in statuses if value))`; unchecked `tuple((label for value, label in statuses if not value))`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H-T488 / PSC-XII-SUPPORT-COMPARISON

Source symbol(s): `komorebi_math.langlands.global_.hecke.SupportComparison.construct`. No attached provenance record under this label.

Locations: `langlands/global_/hecke.py:126`. **Direct base sites:** `H-C188`.

`H-C188`: status `Exactness.EXACT`; checked `('finite declared component sets',)`; unchecked `()`. Residual keys: none recorded (computed/default when not literal).

Observed examples: none recorded. **Literal test mentions:** none recorded.

H.8 Certificate construction-site matrix

The static scan identifies 357 base constructions and 10 specialized/wrapper constructions. Every construction has its complete argument expressions and source fragment in the JSON ledger. This matrix provides the callable, locus, validity/status rule and cross-reference label. It does not claim that every site was executed. The 57-example replay observed 139 base sites; 218 base sites were not observed by that instrumentation.

Construction group: algorithms

H-C001 `komorebi_math.algorithms.compiler.compile_tree_lagrangian`; `algorithms/compiler.py:119`.

Validity `True`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-VIII-T30'`. Observed examples `EX-E-034`.

H-C002 `komorebi_math.algorithms.compiler.compile_tree_budget`; `algorithms/compiler.py:231`.

Validity `int(plan.quantized_error) <= int(budget)`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-VIII-T33'`. Observed examples `EX-E-034`.

H-C003 `komorebi_math.algorithms.discovery.discover_packet_support`; `algorithms/discovery.py:81`.

Validity `True`; status `Exactness.HEURISTIC`; tolerance `threshold`. Label expression `'PSC-VIII-H01'`. Observed examples none recorded.

H-C004 `komorebi_math.algorithms.discovery.discover_block_diagonal_low_rank`; `algorithms/discovery.py:149`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-VIII-T13'`. Observed examples none recorded.

H-C005 `komorebi_math.algorithms.gpu.NumpyPacketExecutor.apply`; `algorithms/gpu.py:41`.

Validity `True`; status `Exactness.NUMERICAL`; tolerance `None`. Label expression `'PSC-VIII-C01'`. Observed examples none recorded.

H-C006 `komorebi_math.algorithms.gpu.CupyPacketExecutor.apply`; `algorithms/gpu.py:99`.

Validity `True`; status `Exactness.NUMERICAL`; tolerance `None`. Label expression `'PSC-VIII-C02'`. Observed examples none recorded.

H-C007 `komorebi_math.algorithms.ir.PacketIR.certificate`; `algorithms/ir.py:259`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-VIII-T01'`. Observed examples `EX-E-035`.

H-C008 `komorebi_math.algorithms.krylov.krylov_basis`; `algorithms/krylov.py:75`.

Validity `orthogonality <= 100 * tolerance_value`; status `Exactness.NUMERICAL`; tolerance `100 * tolerance_value`. Label expression `'PSC-VIII-T20'`. Observed examples none recorded.

H-C009 `komorebi_math.algorithms.krylov.conjugate_gradient`; `algorithms/krylov.py:183`.

Validity `True`; status `Exactness.NUMERICAL`; tolerance `threshold`. Label expression `'PSC-VIII-T22'`. Observed examples none recorded.

H-C010 `komorebi_math.algorithms.krylov.conjugate_gradient`; `algorithms/krylov.py:259`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `threshold`. Label expression `'PSC-VIII-T22'`. Observed examples `EX-E-055`.

Validity `valid`; status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; tolerance `None if self.backend.exact else 1e-10`. Label expression `'PSC-II-C21'`. Observed examples none recorded.

H-C297 `komorebi_math.refinement.defects.LinearRefinementDefect.resolvent`; `refinement/defects.py:157`.

Validity `valid`; status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; tolerance `None if self.backend.exact else 1e-09`. Label expression `'PSC-II-T22'`. Observed examples none recorded.

H-C298 `komorebi_math.refinement.defects.LinearRefinementDefect.exponential`; `refinement/defects.py:210`.

Validity `valid`; status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; tolerance `None if self.backend.exact else 1e-08`. Label expression `'PSC-II-T24'`. Observed examples none recorded.

H-C299 `komorebi_math.refinement.defects.multilevel_defect`; `refinement/defects.py:290`.

Validity `valid`; status `Exactness.EXACT if algebra.exact else Exactness.NUMERICAL`; tolerance `None if algebra.exact else 1e-09`. Label expression `'PSC-II-T25'`. Observed examples none recorded.

H-C300 `komorebi_math.refinement.lattices.LatticePacketData.certificate`; `refinement/lattices.py:140`.

Validity `bool(valid)`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-II-D12'`. Observed examples `EX-E-016`.

H-C301 `komorebi_math.refinement.lattices.LatticePacketData.gluing_weight_certificate`; `refinement/lattices.py:212`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-II-T13'`. Observed examples `EX-E-016`.

H-C302 `komorebi_math.refinement.lattices.refinement_weight_monotonicity`; `refinement/lattices.py:274`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-II-T15'`. Observed examples none recorded.

H-C303 `komorebi_math.refinement.polyphase.PolyphaseRefinement.certificate`; `refinement/polyphase.py:276`.

Validity `valid`; status `exactness`; tolerance `None if exact else threshold`. Label expression `'KM-B15-T01'`. Observed examples `EX-E-003`, `EX-E-007`.

H-C304 `komorebi_math.refinement.polyphase.PolyphaseRefinementTower.coherence_certificate`; `refinement/polyphase.py:626`.

Validity `valid`; status `Exactness.EXACT if exact else Exactness.NUMERICAL`; tolerance `None if exact else float(tolerance)`. Label expression `'KM-B15-T02'`. Observed examples `EX-E-003`.

H-C305 `komorebi_math.refinement.polyphase.LatticePolyphaseRefinement.certificate`; `refinement/polyphase.py:857`.

Validity `valid`; status `Exactness.EXACT if exact else Exactness.NUMERICAL`; tolerance `None if exact else float(tolerance)`. Label expression `'KM-B15-T03'`. Observed examples none recorded.

H-C306 `komorebi_math.refinement.smith.SmithDecomposition.certificate`; `refinement/smith.py:67`.

Validity `bool(valid)`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-II-SNF'`. Observed examples `EX-E-016`.

H-C307 `komorebi_math.refinement.smith.SmithCongruenceProblem.solve`; `refinement/smith.py:236`.

Validity `bool(valid)`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-II-T18'`. Observed examples `EX-E-016`.

H-C308 `komorebi_math.refinement.towers.PacketRefinement.certificate`; `refinement/towers.py:72`.

Validity `bool(valid)`; status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; tolerance `None if self.backend.exact else max(self.coarse.tolerance, self.fine.tolerance)`. Label expression `'PSC-II-T03'`. Observed examples `EX-E-047`.

H-C309 `komorebi_math.refinement.towers.RefinementTower.certificate`; `refinement/towers.py:201`.

Validity `all((certificate.valid for certificate in certificates))`; status `Exactness.EXACT if all((certificate.exactness is Exactness.EXACT for certificate in certificates)) else Exactnes...`; tolerance `None if all((certificate.exactness is Exactness.EXACT for certificate in certificates))...`. Label expression `'PSC-II-T05'`. Observed examples none recorded.

H-C310 `komorebi_math.refinement.weighted.WeightedTransferGraph.truncated_inverse`; `refinement/weighted.py:296`.

Validity `bool(valid)`; status `exactness`; tolerance `None`. Label expression `'PSC-II-T10'`. Observed examples none recorded.

H-C311 `komorebi_math.refinement.weighted.WeightedTransferGraph.exact_inverse_if_acyclic`; `refinement/weighted.py:341`.

Validity `valid`; status `Exactness.EXACT if self.backend.exact else Exactness.NUMERICAL`; tolerance `None if self.backend.exact else self.packet_system.tolerance`. Label expression `'PSC-II-C11'`. Observed examples `EX-E-047`.

Construction group: release

H-C312 `komorebi_math.release.contract.check_release_contract`; `release/contract.py:91`.

Validity `not failed`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-RELEASE-CONTRACT-021'`. Observed examples none recorded.

H-C313 `komorebi_math.release.documentation.check_stable_documentation`; `release/documentation.py:296`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-DOCS-017'`. Observed examples none recorded.

H-C314 `komorebi_math.release.evidence.check_validation_evidence`; `release/evidence.py:286`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-EVIDENCE-017'`. Observed examples none recorded.

H-C315 `komorebi_math.release.gpu.qualify_gpu`; `release/gpu.py:152`.

Validity `not failures`; status `Exactness.NUMERICAL`; tolerance `1e-10`. Label expression `'KM-GPU-016'`. Observed examples none recorded.

H-C316 `komorebi_math.release.readiness.check_beta_readiness`; `release/readiness.py:42`.

Validity `not failed`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-READINESS-017'`. Observed examples none recorded.

H-C317 `komorebi_math.release.upgrade.check_upgrade_contract`; `release/upgrade.py:134`.

Validity `not failed`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-UPGRADE-017'`. Observed examples none recorded.

Construction group: sequences

H-C318 `komorebi_math.sequences.automatic.AutomaticSequence.certificate`; `sequences/automatic.py:159`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-SEQ-AUTOMATIC'`. Observed examples `EX-E-001`.

H-C319 `komorebi_math.sequences.compiler._model_certificate`; `sequences/compiler.py:190`.

Validity `valid`; status `Exactness.EXACT if exact else Exactness.CONDITIONAL`; tolerance `None`. Label expression `None`. Observed examples `EX-E-017`, `EX-E-051`.

H-C320 `komorebi_math.sequences.compiler.compile_sequence`; `sequences/compiler.py:265`.

Validity `True`; status `Exactness.CONDITIONAL`; tolerance `None`. Label expression `None`. Observed examples none recorded.

H-C321 `komorebi_math.sequences.compiler.compile_sequence`; `sequences/compiler.py:278`.

Validity `True`; status `Exactness.EXACT if sequence.exact else Exactness.NUMERICAL`; tolerance `None`. Label expression `None`. Observed examples none recorded.

H-C322 `komorebi_math.sequences.holonomic.HolonomicRecurrence.certificate`; `sequences/holonomic.py:139`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-SEQ-HOLONOMIC'`. Observed examples `EX-E-001`.

Construction group: signals

H-C323 `komorebi_math.signals.adaptive._result`; `signals/adaptive.py:99`.

Validity `finite`; status `Exactness.NUMERICAL`; tolerance `None`. Label expression `'KM-DSP-D12'`. Observed examples `EX-E-040`.

H-C324 `komorebi_math.signals.approximation.estimate_positive_packet_1d`; `signals/approximation.py:104`.

Validity `True`; status `Exactness.HEURISTIC`; tolerance `None`. Label expression `'PSC-V-H01'`. Observed examples none recorded.

H-C325 `komorebi_math.signals.convolution.PolyphaseConvolution.certificate`; `signals/convolution.py:199`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T07'`. Observed examples `EX-E-036`.

H-C326 `komorebi_math.signals.denoise.HaarDecomposition.certificate`; `signals/denoise.py:178`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T06'`. Observed examples `EX-E-040`.

H-C327 `komorebi_math.signals.denoise.wavelet_denoise`; `signals/denoise.py:299`.

Validity `finite and shrinkage_residual <= 1e-12`; status `Exactness.NUMERICAL`; tolerance `1e-12`. Label expression `'KM-DSP-D10'`. Observed examples `EX-E-040`.

H-C328 `komorebi_math.signals.denoise.denoising_risk_certificate`; `signals/denoise.py:349`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `allowed`. Label expression `'KM-DSP-C03'`. Observed examples `EX-E-040`.

H-C329 `komorebi_math.signals.edge_recovery.recover_jumps`; `signals/edge_recovery.py:129`.

Validity `valid`; status `exactness`; tolerance `None`. Label expression `'PSC-V-T19'`. Observed examples none recorded.

H-C330 `komorebi_math.signals.edge_recovery.recover_jumps_subgaussian`; `signals/edge_recovery.py:195`.

Validity `result.certificate.valid`; status `Exactness.CONDITIONAL`; tolerance `None`. Label expression `'PSC-V-T20'`. Observed examples none recorded.

H-C331 `komorebi_math.signals.fft_convolution.certified_overlap_add_convolve`; `signals/fft_convolution.py:236`.

Validity `bool(value.shape == reference.shape and residual <= tolerance * scale)`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T10'`. Observed examples `EX-E-040`.

H-C332 `komorebi_math.signals.filterbanks.PeriodicFilterBank.perfect_reconstruction_certificate`; `signals/filterbanks.py:132`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T09'`. Observed examples none recorded.

H-C333 `komorebi_math.signals.filterbanks.HaarFilterBank.certificate`; `signals/filterbanks.py:206`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T10'`. Observed examples none recorded.

H-C334 `komorebi_math.signals.filterbanks.PeriodicLiftingScheme.certificate`; `signals/filterbanks.py:281`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T11'`. Observed examples none recorded.

H-C335 `komorebi_math.signals.filterbanks.FiniteFilterBank.report`; `signals/filterbanks.py:353`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T09'`. Observed examples none recorded.

H-C336 `komorebi_math.signals.filtering.FIRFilter.certificate`; `signals/filtering.py:181`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-C02'`. Observed examples `EX-E-040`.

H-C337 `komorebi_math.signals.filtering.stream_fir_filter`; `signals/filtering.py:425`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T05'`. Observed examples `EX-E-040`.

H-C338 `komorebi_math.signals.nonlinear.packet_product`; `signals/nonlinear.py:112`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `1e-10`. Label expression `'PSC-V-T51'`. Observed examples none recorded.

H-C339 `komorebi_math.signals.nonlinear.packet_product`; `signals/nonlinear.py:141`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `1e-10`. Label expression `'PSC-V-T51'`. Observed examples none recorded.

H-C340 `komorebi_math.signals.polyphase.PolyphaseCoordinates.certificate`; `signals/polyphase.py:121`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `float(tolerance)`. Label expression `'PSC-V-T02'`. Observed examples `EX-E-036`.

H-C341 `komorebi_math.signals.polyphase.LatticePolyphaseCoordinates.certificate`; `signals/polyphase.py:369`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T04'`. Observed examples none recorded.

H-C342 `komorebi_math.signals.recovery.recover_separated_jumps`; `signals/recovery.py:117`.

Validity `True`; status `Exactness.CONDITIONAL`; tolerance `None`. Label expression `'PSC-V-T36'`. Observed examples `EX-E-052`.

H-C343 `komorebi_math.signals.recovery.recover_jumps_subgaussian`; `signals/recovery.py:182`.

Validity `result.certificate.valid`; status `Exactness.CONDITIONAL`; tolerance `None`. Label expression `'PSC-V-C37'`. Observed examples none recorded.

H-C344 `komorebi_math.signals.recovery.detect_piecewise_polynomial_breaks`; `signals/recovery.py:253`.

Validity `True`; status `Exactness.CONDITIONAL`; tolerance `None`. Label expression `'PSC-V-T43'`. Observed examples none recorded.

H-C345 `komorebi_math.signals.recursive.LinearFilter.stability_certificate`; `signals/recursive.py:160`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `allowed`. Label expression `'KM-DSP-C04'`. Observed examples `EX-E-040`.

H-C346 `komorebi_math.signals.recursive.stream_lfilter`; `signals/recursive.py:292`.

Validity `bool(streamed.shape == reference.shape and residual <= tolerance * scale)`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T09'`. Observed examples `EX-E-040`.

H-C347 `komorebi_math.signals.resampling.RationalResamplingPlan.certificate`; `signals/resampling.py:186`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T06'`. Observed examples `EX-E-040`.

H-C348 `komorebi_math.signals.singular_packets.retained_packet_reconstruct`; `signals/singular_packets.py:242`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T17'`. Observed examples none recorded.

H-C349 `komorebi_math.signals.singular_packets.retained_packet_reconstruction`; `signals/singular_packets.py:304`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T18'`. Observed examples `EX-E-052`.

H-C350 `komorebi_math.signals.singular_packets.scalar_region_error`; `signals/singular_packets.py:438`.

Validity `residual <= tolerance`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T21'`. Observed examples none recorded.

H-C351 `komorebi_math.signals.singular_packets.overlap_matrix_error`; `signals/singular_packets.py:481`.

Validity `residual <= tolerance`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T22'`. Observed examples none recorded.

H-C352 `komorebi_math.signals.spectral._power_certificate`; `signals/spectral.py:144`.

Validity `bool(valid)`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `theorem_id`. Observed examples `EX-E-040`.

H-C353 `komorebi_math.signals.spectral.cross_spectrum`; `signals/spectral.py:369`.

Validity `finite and bound_residual <= 1e-12`; status `Exactness.NUMERICAL`; tolerance `1e-12`. Label expression `'KM-DSP-D07'`. Observed examples `EX-E-040`.

H-C354 `komorebi_math.signals.spectral.parseval_certificate`; `signals/spectral.py:418`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T04'`. Observed examples none recorded.

H-C355 `komorebi_math.signals.streaming.stream_stft`; `signals/streaming.py:330`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T07'`. Observed examples `EX-E-040`.

H-C356 `komorebi_math.signals.time_frequency.FrameBatch.certificate`; `signals/time_frequency.py:83`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-DSP-D02'`. Observed examples `EX-E-040`.

H-C357 `komorebi_math.signals.time_frequency.STFTResult.roundtrip_certificate`; `signals/time_frequency.py:235`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T03'`. Observed examples `EX-E-040`.

H-C358 `komorebi_math.signals.time_frequency.istft`; `signals/time_frequency.py:390`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T03'`. Observed examples `EX-E-040`.

H-C359 `komorebi_math.signals.wavelets.HaarPacketTree.reconstruction_certificate`; `signals/wavelets.py:188`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'PSC-V-T13'`. Observed examples `EX-E-036`.

H-C360 `komorebi_math.signals.wavelets.best_basis`; `signals/wavelets.py:302`.

Validity `True`; status `Exactness.EXACT`; tolerance `None`. Label expression `'PSC-V-T14'`. Observed examples none recorded.

H-C361 `komorebi_math.signals.windows.overlap_add_certificate`; `signals/windows.py:243`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-C01'`. Observed examples none recorded.

H-C362 `komorebi_math.signals.windows.canonical_dual_window`; `signals/windows.py:295`.

Validity `valid`; status `Exactness.NUMERICAL`; tolerance `tolerance`. Label expression `'KM-DSP-T02'`. Observed examples none recorded.

Construction group: stable_contract.py

H-C363 `komorebi_math.stable_contract.check_stable_contract`; `stable_contract.py:53`.

Validity `valid`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-STABLE-CONTRACT-016'`. Observed examples none recorded.

Construction group: stable_semantics.py

H-C364 `komorebi_math.stable_semantics.run_stable_semantics_fixture`; `stable_semantics.py:415`.

Validity `not failed`; status `Exactness.EXACT`; tolerance `None`. Label expression `'KM-STABLE-SEM-016'`. Observed examples none recorded.

Construction group: unified.py

H-C365 `komorebi_math.unified.UnifiedSystem.validate`; `unified.py:126`.

Validity `valid`; status `Exactness.EXACT if exact else Exactness.NUMERICAL`; tolerance `None if exact else max(1e-10, 0.0 if self.seed_system is None else self.seed_system.tol...`. Label expression `None`. Observed examples `EX-E-043`.

Construction group: verify

H-C366 `komorebi_math.verify.core.VerificationReport.certificate`; `verify/core.py:52`.

Validity `self.passed`; status `Exactness.NUMERICAL`; tolerance `None`. Label expression `None`. Observed examples none recorded.

H-C367 `komorebi_math.verify.expression.run_expression_verification.binding_certificate_propagation`; `verify/expression.py:418`.

Validity `True`; status `Exactness.CONDITIONAL`; tolerance `None`. Label expression `'EXPR.TEST.CONDITIONAL_BINDING'`. Observed examples none recorded.

H.9 Dynamic labels and typed carriers

Forty-two dynamic declaration sites accept, propagate, decode or compose labels. The finite catalog does not enumerate arbitrary user strings or all compositions. Each expression below is retained exactly in the ledger. A supplied label never substitutes for its mathematical assumptions.

Source	Dynamic label expression

H.10 Executed evidence and index integrity

Check	Observed result
Pinned package source tests	1,203
New index/interface tests	1,261
Replayed Python examples	57
Output predicates	190
Base construction invocations	1,842
Base require invocations	841
Observed distinct nonempty labels	142
Observed base construction sites	139
Unobserved base construction sites	218
Source/installed package files compared	366

The construction and require counts overlap, and multiple invocations can represent the same finite example or label. A construction can hold an invalid or conditional result. The example contracts check expected output and preserved negative conclusions, not unconditional validity of every certificate. The source suite passes as a suite; its pass count is not a per-theorem proof mapping.

All 300 Python package source files are hashed in the index. Each constructor, type, carrier and provenance row has a source path, line range and full SHA-256. The index records the frozen mathematical implementation and distribution without modifying them.

H.11 Reproduction, source identity and closure

The working tools under `tools/block40` regenerate the static inventory, validate the separately installed wheel against all 366 package files, replay the 57 Python example contracts, build the observed crosswalk, execute the source/index and behavioral tests, and generate the cumulative and standalone documentation. The source tests are a separate package suite. The new reference tests test the index and deliberately chosen interface boundaries; they are not additional mathematical theorems.

Use a fresh output directory for the example replay. It does not overwrite an earlier evidence run. The replay delegates the original base constructor and require method, records observations in the example interpreter, then restores the methods. Independent specialized-only certificates and separately launched child interpreters are outside that instrumentation boundary. The original script assertions, output predicates and package-origin checks remain active.

The directory verifier binds every delivered file and executable mode. The build gate requires current source/test/replay/document hashes. These are local integrity and execution records, not authenticated signatures. Reproducing Markdown, JSON and LaTeX is a separate claim from binary reproducibility of independently rebuilt PDFs. The final ZIP's own hash belongs in the external delivery record to avoid circular self-attestation.

Reference boundaries. This source-bound certificate and theorem-label index does not resolve producer-hardening issues, establish a bijection between labels and mathematical theorems, or verify correspondence with external Lean declarations. Appendix I provides the separate exception and diagnostic reference.

The recorded audit did not qualify native Windows/PowerShell, other Python versions, CUDA, strict MkDocs, fully dependency-isolated installation or final publication. Prior GPU and platform failures remain negative observations. It included no new Lean proof audit. Appendix O identifies the separate final-source qualification records.

Appendix I. Exceptions and diagnostic cookbook

Start with the symptom. This cookbook is intended for use beside a failing program. Keep the smallest input that still reproduces the problem and use I.2 to record the run before changing it.

What you observe	First place to look	Next question
A Python exception or traceback	I.3 and the matching recipe	Which input contract or dependency produced the refusal?
A returned object whose result is unusable	I.4 and Appendix H	Is the certificate invalid, conditional, or numerical when exact data are required?
A warning, or a warning treated as an exception	I.4 and Appendix L	Which warning filter is active, and did the function body run?
A failed command-line run	I.4 and Appendix F	Did argument parsing fail, or did the selected handler execute and refuse the task?

Use the recovery as a comparison. Run a cookbook recipe's setup before its trigger, and run its recovery separately if the trigger raises. Compare the failing input with the control input to identify the changed condition. Then repair that condition in your own problem and rerun its original check. This makes the recipe a diagnostic example rather than a replacement for your data.

I.1 Scope and evidence channels

This appendix answers a practical question: when a Komorebi Math computation does not produce the intended usable result, what exactly failed, where is that behavior defined, and what is a justified next action? It is a reference to **Komorebi Math 1.0.0b4, Repair R2, wheel build tag 2**. All runtime observations are bound to that source baseline.

Four channels must be read separately. An exception interrupts the Python call. A returned certificate can report an invalid or conditional result without interrupting it. A warning reports a condition through Python's warning policy and may leave the return value unchanged. A command-line process has an exit status plus separate stdout and stderr streams. A zero exit, an exactness label, a nonempty output file, and a favorable stored validity flag are not interchangeable evidence.

The static census includes every explicit `raise`, `except`, and `assert` statement and the recognized `warnings.warn` call in all 300 shipped Python package source files. It includes the package's verification modules. It does not include the test tree, third-party source, operating-system internals, or arbitrary user callbacks. A function can propagate a dependency error without containing any explicit raise. A syntax census is therefore **not a complete set of all runtime exceptions**.

Each electronic site record contains a qualified owner, source path, exact line range, source-file SHA-256, complete statement, exception or handler expression, and syntactic ancestor guards. A guard is a description of the source branch, not a proof that the predicate is sufficient, reachable, or true for every caller. Bare re-raises have no invented exception type. Handler records distinguish syntactic return, pass, continue, raise and re-raise actions, without claiming a full control-flow analysis.

The cookbook executes representative failing inputs and paired valid or diagnostic-control inputs in a separately installed wheel. It does not execute every one of the thousands of static branches. Missing-dependency discovery, a compiler timeout, and the planned-feature registry guard use explicitly labeled controlled fixtures. They are not claims that a native dependency was absent, a real compiler hung, or an existing feature was implemented during the test.

I.2 Triage before changing the mathematics

Capture the channel and preserve the original input. Record the exact command or API call, the last exception and its cause chain, exit status, stdout, stderr, certificate fields and generated-file names. Keep a copy of failed persisted inputs before regeneration. Messages can contain paths or data, so review them before sharing a report externally.

Confirm the executed artifact. Record `komorebi_math.__file__`, the package version, Python executable, optional backend selection, source checksum and wheel checksum. The public version alone cannot distinguish the stale pre-repair distribution from the repaired build-2 wheel. Use the R2 release parity checks rather than assuming that an import from a neighboring source checkout validates the installed artifact.

Locate the actual refusal. Look up the message or symbol in `Block41_Raise_Site_Lookup.tsv` or the JSON inventory. Retain `__cause__`: a `ValidationError` around a portable load can originate in a missing file, invalid UTF-8, malformed JSON, a schema mismatch, a checksum mismatch or a type-specific constructor. Re-running the mathematical calculation does not repair all of those causes.

Correct the violated contract. Shape errors call for compatible spaces and dimensions. Relation errors call for typed parallel paths. Positive-evidence failures call for a justified probability model. Exact-route errors call for exact inputs, not a cast of already rounded data. Resource refusals call for a smaller request or a justified explicit budget, not an unbounded retry. A returned negative certificate calls for inspection of its producer and prerequisites.

Recheck, do not relabel. Do not suppress a failure with `validate=False`, overwrite a certificate's validity, remove an unchecked hypothesis, enlarge a tolerance without justification, or recompute a checksum merely to conceal a damaged artifact. The positive recipe inputs are independent small fixtures that satisfy the contract; they are not permission to replace the user's real data with arbitrary convenient values.

I.3 Public exception hierarchy and catch boundaries

The nine package exception classes are defined in `komorebi_math.exceptions`. The project warning class is defined separately in `komorebi_math.compatibility`. This reference does not classify the `IntegrationError` data record or the `ErrorGuarantee` enum as exception classes merely because their names contain the word Error.

`ValidationError` inherits both `KomorebiMathError` and `ValueError`. `DimensionError`, `RelationError`, and `ResourceLimitError` inherit from it. Catching `ValueError` before a more specific package subtype can hide whether the caller violated a geometry contract or exceeded a resource bound. `FeatureNotImplementedError` also inherits `NotImplementedError`; its multiple inheritance should be considered when ordering handlers.

`BackendUnavailableError`, `ExactnessError`, and `AssumptionError` are package exceptions but not ValidationError subtypes. Ordinary `ValueError`, `TypeError`, `KeyError`, `OSError` and dependency exceptions can also propagate. Catching only `KomorebiMathError` is not a universal application boundary. Conversely, catching all `Exception` and returning success destroys the distinction between an expected refusal and an implementation defect.

`ExactnessError` is a declared public type with **no explicit raise site** in this pinned source census. Its name does not imply universal exactness enforcement. The exact-expression literal route instead rejects floating and boolean coefficients with `ValidationError`; the numerical packet route can return a valid `NUMERICAL` certificate without raising at all.

Class	Direct base(s)	Explicit package raise sites
`KomorebiDeprecationWarning`	`DeprecationWarning`	0
`AssumptionError`	`KomorebiMathError`	17
`BackendUnavailableError`	`KomorebiMathError`	31
`DimensionError`	`ValidationError`	686
`ExactnessError`	`KomorebiMathError`	0
`FeatureNotImplementedError`	`NotImplementedError`, `KomorebiMathError`	1
`KomorebiMathError`	`Exception`	0
`RelationError`	`ValidationError`	7
`ResourceLimitError`	`ValidationError`	63
`ValidationError`	`KomorebiMathError`, `ValueError`	2204

Class	Direct base(s)	Explicit package raise sites

A zero in the last column means no explicit `raise Class(...)` was found, not that callers cannot instantiate or raise the class. The warning class is emitted through `warnings.warn`, so its explicit-raise count is also zero.

KomorebiDeprecationWarning

Warning category for explicit Komorebi Math API deprecations.

Source: `komorebi_math/compatibility.py`, lines 229-230. Bases: `builtins.DeprecationWarning`. Source SHA-256: `9422447e4d0c996c6474c93c326722ad2e449ceb35f52211c2eb70fae12543b7`.

AssumptionError

Raised when a required mathematical assumption is not satisfied.

Source: `komorebi_math/exceptions.py`, lines 30-31. Bases: `komorebi_math.exceptions.KomorebiMathError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

BackendUnavailableError

Raised when an optional computation backend is not installed.

Source: `komorebi_math/exceptions.py`, lines 22-23. Bases: `komorebi_math.exceptions.KomorebiMathError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

DimensionError

Raised when matrix, vector, or packet dimensions do not agree.

Source: `komorebi_math/exceptions.py`, lines 14-15. Bases: `komorebi_math.exceptions.ValidationError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

ExactnessError

Raised when an exact operation is requested from an inexact backend.

Source: `komorebi_math/exceptions.py`, lines 26-27. Bases: `komorebi_math.exceptions.KomorebiMathError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

FeatureNotImplementedError

Raised by a deliberately declared placeholder feature.

Source: `komorebi_math/exceptions.py`, lines 38-39. Bases: `builtins.NotImplementedError`, `komorebi_math.exceptions.KomorebiMathError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

KomorebiMathError

Base class for all public package exceptions.

Source: `komorebi_math/exceptions.py`, lines 6-7. Bases: `builtins.Exception`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

RelationError

Raised when a grammar relation is malformed or violated.

Source: `komorebi_math/exceptions.py`, lines 18-19. Bases: `komorebi_math.exceptions.ValidationError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

ResourceLimitError

Raised before a computation exceeds an explicit resource contract.

Source: `komorebi_math/exceptions.py`, lines 34-35. Bases: `komorebi_math.exceptions.ValidationError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

ValidationError

Raised when a mathematical object fails a declared validation rule.

Source: `komorebi_math/exceptions.py`, lines 10-11. Bases: `komorebi_math.exceptions.KomorebiMathError`, `builtins.ValueError`. Source SHA-256: `65aee29fea129eec941c2a3667dd3d5dff67680cafb50e37674bb475fa21a1bb`.

I.4 Exceptions, certificates, warnings and exit codes

The base `Certificate.require()` tests the truthiness of its stored `valid` field and raises `ValidationError` when false. It does not recompute residuals, validate a witness, verify a theorem ID or discharge unchecked assumptions. Appendix H describes specialized protocols, which must not be guessed from a common attribute name. The supplied diagnostic helper observes base-certificate fields without changing them, records whether `valid` is an actual bool, and always leaves `proof_admitted` false.

The packet-validation bypass from Appendix H remains present: a self-adjoint matrix that is not a projector can receive a favorable Hilbert flag after `validate=False`, while its base packet-axiom certificate fails. The cookbook repeats the discrepancy as a regression boundary. The recovery is to require the prerequisite packet axioms, not to promote the specialized flag into a proof.

`KomorebiDeprecationWarning` is a `DeprecationWarning` subclass. One package warning-emission site constructs its message from the API name, since version, optional replacement, removal version and reason. The cookbook captures that category explicitly and also promotes it to an exception using a local warning filter. Those two outcomes are consequences of policy applied to the same source behavior, not two different mathematical failures.

Python assert statements form a separate verification channel. They can be disabled by optimized execution. The reference and source test runs keep assertions active. The 411 indexed assertions include internal and verification assertions; they are not all user-input guards or independently proved invariants. Never treat an optimized run that omitted assertions as equivalent validation.

The pinned CLI parses arguments and invokes the handler without one universal exception-to-JSON wrapper. Parser usage failures normally exit 2. An uncaught handler exception normally produces a traceback and exit 1. A handler can also intentionally return 1 with a negative certificate, or return 2 for its own semantic selector checks. Read the output and handler record before assigning a meaning to the number. `langlands completion` with unsatisfied assumptions remains an intentional negative result. Displaying help is navigation, not completion of those assumptions.

A compiler child return code 124 in a `LatexCompilation` record is the wrapper's timeout convention. It is not a mathematical error class. An outer process exit code must be recorded separately. Native launcher and PowerShell exit propagation remain pending platform work; no Linux recipe is silently counted as a native Windows acceptance test.

I.5 Cookbook execution contract

Each recipe prints its setup, failing or diagnostic trigger, expected observed outcome, explanation and valid recovery/control. The blocks share one fresh workspace named `work`, supplied as a `pathlib.Path` by the runner. To reproduce a file-producing recipe manually, open a fresh temporary directory first:

```
from pathlib import Path
from tempfile import TemporaryDirectory

workspace = TemporaryDirectory(prefix="km-diagnostic-")
work = Path(workspace.name)
# Run the recipe setup, then its trigger under the shown exception policy.
# Run its recovery/control and inspect the outcome before cleanup.
workspace.cleanup()
```

Do not concatenate an uncaught failing block with its recovery and expect execution to continue. The provided runner checks the exact exception class name, message fragment, cause chain and source frames, then executes the separate recovery block in the same child. A recipe marked observation uses explicit assertions about the returned negative status or warning; it is not expected to throw immediately.

Every child has a bounded execution timeout. All mathematical imports must resolve to the separate pinned wheel. The seven CLI recipes invoke the actual isolated entry point in an additional child with no source `PYTHONPATH`; those nested CLI children do not have a per-module origin observer. Their origin basis is the selected virtual-environment executable, isolated mode and the parent package-parity preflight. This distinction is retained in the replay metadata.

The portable-file recipes test preservation of existing sentinel files on overwrite refusal. The compiler recipes use temporary directories and shell escape remains disabled. A deliberately invalid small TeX input is compiled by the installed engine, and an independent valid TeX fixture is compiled successfully. Discovery absence and timeout behavior are controlled separately using mocks, as labeled. These tests do not qualify compilation of arbitrary hostile TeX.

Mathematical validation

XI-D001 / No projectors supplied

Meaning. An empty family cannot resolve the ambient space.

Recovery decision. Provide a nonempty complete projector family.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `at least one`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.eye(2)])
assert p.certificate().require().valid
```

Observed explicit source site(s): `XI-R0777` at `core/packets.py:64`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D001/receipt.json`. Its hash is `c288e100c0ba248e91c20b9e0f57ae5ec056b3c0eaf104e47dfbe6a2de370f42`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D002 / Nonsquare projector

Meaning. The projector is not an endomorphism of one finite space.

Recovery decision. Correct the matrix geometry before checking the projector axioms.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.DimensionError`. Expected message fragment: `square`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([np.ones((2, 3))])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.eye(2)])
assert p.dimension == 2
```

Observed explicit source site(s): `XI-R0778` at `core/packets.py:70`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D002/receipt.json`. Its hash is `bd77dfdfe6c178e9e6801b9cbeef149d8896e8d62390c726a161ff4fe80a4f77`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D003 / Projector dimensions disagree

Meaning. Every projector must act on the same ambient dimension.

Recovery decision. Use compatible blocks in one declared coordinate system.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.DimensionError`. Expected message fragment: `common size`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([np.eye(2), np.eye(3)])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.diag([1.0, 0.0]), np.diag([0.0, 1.0])])
p.certificate().require()
```

Observed explicit source site(s): `XI-R0779` at `core/packets.py:72`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D003/receipt.json`. Its hash is `7bfbb2e1ff92cc1933690986f2a0628eef827d69cdfa30431072bfed9ae5a15e`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D004 / Name count mismatch

Meaning. Names and projectors have different cardinalities.

Recovery decision. Provide exactly one name per projector.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `same length`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([np.eye(2)], names=['a', 'b'])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.eye(2)], names=['all'])
assert p.index('all') == 0
```

Observed explicit source site(s): `XI-R0780` at `core/packets.py:79`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D004/receipt.json`. Its hash is `f06004a6c77e4ad0be5a26a998a9c3c79ba3e98634409702a530e8f5b3cec6b5`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D005 / Duplicate packet names

Meaning. Name lookup would be ambiguous.

Recovery decision. Assign distinct labels without changing the projector meaning.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `unique`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([np.diag([1.0, 0.0]), np.diag([0.0, 1.0])], names=['a', 'a'])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.diag([1.0, 0.0]), np.diag([0.0, 1.0])], names=['a', 'b'])
assert p.names == ('a', 'b')
```

Observed explicit source site(s): `XI-R0781` at `core/packets.py:81`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D005/receipt.json`. Its hash is `10ed80edd352948841571845c3c2cc779b4fddf9f06ca25805987dc056449d6e`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D006 / Vector belongs to another dimension

Meaning. The input vector is not in the declared ambient space.

Recovery decision. Reconcile the data dimension or rebuild the correct packet system.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.DimensionError`. Expected message fragment: `vector dimension`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([np.eye(2)]).analyze([1, 2, 3])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.eye(2)])
assert np.allclose(p.analyze([1, 2]).reconstruct(), [1, 2])
```

Observed explicit source site(s): `XI-R0783` at `core/packets.py:157`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D006/receipt.json`. Its hash is `18a6507e4ef7bbf77455aeef3198812fb04d4e81d32bc63026ab5512787b2346`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D007 / Projector axioms fail

Meaning. Construction calls the packet certificate and refuses failed axioms.

Recovery decision. Correct the projectors. Do not use validate=False or enlarge tolerance merely to suppress failure.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `complete packet`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([2 * np.eye(2)])
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.eye(2)])
p.certificate().require()
```

Observed explicit source site(s): `XI-R0334` at `certificates.py:45`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D007/receipt.json`. Its hash is `6267c0fa27bdaa297df1fa256da1d1bee6e542b481afa32d39737805c7fa91cf`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D008 / Unknown packet name

Meaning. The name does not occur in the stored packet name tuple.

Recovery decision. Inspect p.names and request a declared name. The ValueError cause is preserved.

Evidence mode: native finite input. **Observed exception:** `builtins.KeyError`. Expected message fragment: `missing`. **Explicit cause:** `builtins.ValueError`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
PacketSystem([np.eye(2)], names=['all']).index('missing')
```

Valid recovery or diagnostic control

```
p = PacketSystem([np.eye(2)], names=['all'])
assert p.index('all') == 0
```

Observed explicit source site(s): `XI-R0782` at `core/packets.py:90`.

Implementation lookup: `komorebi_math.core.packets.PacketSystem`. **Executed receipt:** `diagnostic_replay/XI-D008/receipt.json`. Its hash is `9db75c5258467903d44682837dcafce638ebc958f9f551a1a31b8fe069523e66`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Dimension and relation mismatch

XI-D009 / Unnamed relation

Meaning. Every relation needs an identity for registration.

Recovery decision. Correct the typed relation, including its endpoints, before registration.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.RelationError`. Expected message fragment: `requires a name`.

Setup

```
from komorebi_math.core.grammar import OperatorRelation, OperatorWord, OperatorGrammar
w = OperatorWord((), 'X', 'X')
```

Trigger

```
OperatorRelation('', ((1, w),))
```

Valid recovery or diagnostic control

```
r = OperatorRelation('identity-cancel', ((1, w), (-1, w)))
assert r.source == r.target == 'X'
```

Observed explicit source site(s): `XI-R0729` at `core/grammar.py:48`.

Implementation lookup: `komorebi_math.core.grammar.OperatorRelation`. **Executed receipt:** `diagnostic_replay/XI-D009/receipt.json`. Its hash is `c0d8637ea4e1e2c00bf608a2ac6ad9ebd1074a52297e7b37ecdead64096c98f0`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D010 / Empty relation

Meaning. An empty list is not a declared linear relation.

Recovery decision. Correct the typed relation, including its endpoints, before registration.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.RelationError`. Expected message fragment: `at least one term`.

Setup

```
from komorebi_math.core.grammar import OperatorRelation, OperatorWord, OperatorGrammar
w = OperatorWord((), 'X', 'X')
```

Trigger

```
OperatorRelation('r', ())
```

Valid recovery or diagnostic control

```
r = OperatorRelation('identity-cancel', ((1, w), (-1, w)))
assert r.source == r.target == 'X'
```

Observed explicit source site(s): `XI-R0730` at `core/grammar.py:50`.

Implementation lookup: `komorebi_math.core.grammar.OperatorRelation`. **Executed receipt:** `diagnostic_replay/XI-D010/receipt.json`. Its hash is `bba551ca59ab76cb45e593e2bf1afdb01748a7d46f80d506bcafc66bec9c4c41`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D011 / Nonparallel relation terms

Meaning. A relation must compare parallel typed paths.

Recovery decision. Correct the typed relation, including its endpoints, before registration.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.RelationError`. Expected message fragment: `same source and target`.

Setup

```
from komorebi_math.core.grammar import OperatorRelation, OperatorWord, OperatorGrammar
w = OperatorWord((), 'X', 'X')
```

Trigger

```
OperatorRelation('r', ((1, w), (1, OperatorWord((), 'Y', 'Y'))))
```

Valid recovery or diagnostic control

```
r = OperatorRelation('identity-cancel', ((1, w), (-1, w)))
assert r.source == r.target == 'X'
```

Observed explicit source site(s): `XI-R0731` at `core/grammar.py:54`.

Implementation lookup: `komorebi_math.core.grammar.OperatorRelation`. **Executed receipt:** `diagnostic_replay/XI-D011/receipt.json`. Its hash is `997c3fce9c67fff895fe132c20e0adac17046b0fbf1b2ae262b7d4bacecd4cc7`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D012 / Arrow references an unknown vertex

Meaning. An endpoint has no declared vertex.

Recovery decision. Declare the intended vertex or correct the arrow.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `unknown vertex`.

Setup

```
from komorebi_math.core.grammar import OperatorRelation, OperatorWord, OperatorGrammar
w = OperatorWord((), 'X', 'X')
```

Trigger

```
OperatorGrammar(['X'], {'a': ('X', 'Y')})
```

Valid recovery or diagnostic control

```
g = OperatorGrammar(['X', 'Y'], {'a': ('X', 'Y')})
assert g.word('a').target == 'Y'
```

Observed explicit source site(s): `XI-R0736` at `core/grammar.py:111`.

Implementation lookup: `komorebi_math.core.grammar.OperatorGrammar`. **Executed receipt:** `diagnostic_replay/XI-D012/receipt.json`. Its hash is `6948218604648d3dc1b219c021cc1ec72e0744016f68f4235472c454b0a53f01`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Unavailable backend

XI-D013 / Unknown backend name

Meaning. Backend selection is explicit and unknown names do not silently fall back.

Recovery decision. Check the registered selector. NumPy is a numerical replacement only when that meets the task.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.BackendUnavailableError`. Expected message fragment: `unknown or unavailable`. **Explicit cause:** `builtins.KeyError`.

Setup

```
from komorebi_math.backends import get_backend, register_backend
from komorebi_math.backends.numpy import NumpyBackend
import numpy as np
```

Trigger

```
get_backend('not-a-backend')
```

Valid recovery or diagnostic control

```
assert get_backend('numpy').name == 'numpy'
```

Observed explicit source site(s): `XI-R0328` at `backends/__init__.py:36`.

Implementation lookup: `komorebi_math.backends.get_backend`. **Executed receipt:** `diagnostic_replay/XI-D013/receipt.json`. Its hash is `023edcec2085dc133f53193d4fe25a4e6e53bd09a0b0b0486b02c7704272fcb8`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D014 / Duplicate backend registration

Meaning. Registration is protected by default.

Recovery decision. Reuse the registered backend. Replace only as a deliberate extension change.

Evidence mode: native finite input. **Observed exception:** `builtins.ValueError`. Expected message fragment: `already registered`.

Setup

```
from komorebi_math.backends import get_backend, register_backend
from komorebi_math.backends.numpy import NumpyBackend
import numpy as np
```

Trigger

```
register_backend(NumpyBackend())
```

Valid recovery or diagnostic control

```
assert get_backend('numpy').name == 'numpy'
```

Observed explicit source site(s): `XI-R0326` at `backends/__init__.py:17`.

Implementation lookup: `komorebi_math.backends.register_backend`. **Executed receipt:** `diagnostic_replay/XI-D014/receipt.json`. Its hash is `14d60876574ce74be29456051cc04927dfdf9c5149362d1464de71d8699551bd`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D015 / Missing exact dependency (controlled)

Meaning. The missing-import branch is exercised with controlled discovery, not by uninstalling SymPy.

Recovery decision. Use the declared exact dependency when exact arithmetic is required. This numerical control is not an exactness-preserving substitution.

Evidence mode: mocked discovery only; not actual missing installation. **Observed exception:** `komorebi_math.exceptions.BackendUnavailableError`. Expected message fragment: `exact`.

Setup

```
from komorebi_math.backends import get_backend, register_backend
from komorebi_math.backends.numpy import NumpyBackend
import numpy as np
from unittest.mock import patch
import komorebi_math.backends as b
b._BACKENDS.pop('sympy', None)
```

Trigger

```
with patch.object(b, 'find_spec', return_value=None):
    get_backend('sympy')
```

Valid recovery or diagnostic control

```
assert get_backend('numpy').exact is False
```

Observed explicit source site(s): `XI-R0327` at `backends/__init__.py:27`.

Implementation lookup: `komorebi_math.backends.get_backend`. **Executed receipt:** `diagnostic_replay/XI-D015/receipt.json`. Its hash is `77cd9fe177c8109616694463d85e7110484cc32019b5e1c780477296c0e81e4c`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D016 / Singular numerical inverse

Meaning. A dependency exception propagates through the numerical backend.

Recovery decision. Verify invertibility. Use another mathematical problem formulation only when justified.

Evidence mode: native finite input. **Observed exception:** `numpy.linalg.LinAlgError`. Expected message fragment: `Singular matrix`.

Setup

```
from komorebi_math.backends import get_backend, register_backend
from komorebi_math.backends.numpy import NumpyBackend
import numpy as np
```

Trigger

```
get_backend('numpy').inverse(np.zeros((2, 2)))
```

Valid recovery or diagnostic control

```
assert np.allclose(get_backend('numpy').inverse(np.eye(2)), np.eye(2))
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.backends.numpy.NumpyBackend.inverse`. **Executed receipt:** `diagnostic_replay/XI-D016/receipt.json`. Its hash is `68324d58b2438afbbeb13ccb840449ed03b16dc1e5da1b7e16d27afc8284a86f`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Exactness loss

XI-D017 / Floating value on an exact expression route

Meaning. This exact route rejects values outside int/Fraction. It raises ValidationError, not the declared ExactnessError.

Recovery decision. Provide an exact rational witness. Fraction(1,10) expresses one tenth; constructing a Fraction from an already rounded float does not recover intended decimal semantics.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `integer or Fraction`.

Setup

```
from fractions import Fraction
from komorebi_math.expression.model import ExactValueLiteral, RATIONAL_SPACE
```

Trigger

```
ExactValueLiteral(RATIONAL_SPACE, (0.1,))
```

Valid recovery or diagnostic control

```
x = ExactValueLiteral(RATIONAL_SPACE, (Fraction(1, 10),))
assert x.entries == (Fraction(1, 10),)
```

Observed explicit source site(s): `XI-R1276` at `expression/model.py:39`.

Implementation lookup: `komorebi_math.expression.model._fraction`, `komorebi_math.expression.model.ExactValueLiteral`. **Executed receipt:** `diagnostic_replay/XI-D017/receipt.json`. Its hash is `cd3f2f669fdfbf26c140656d255ecd9017b9415975ee5b01aa7ebfbb6f7f6a7d`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D018 / Boolean on an exact expression route

Meaning. This exact route rejects values outside int/Fraction. It raises ValidationError, not the declared ExactnessError.

Recovery decision. Provide an exact rational witness. Fraction(1,10) expresses one tenth; constructing a Fraction from an already rounded float does not recover intended decimal semantics.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `integer or Fraction`.

Setup

```
from fractions import Fraction
from komorebi_math.expression.model import ExactValueLiteral, RATIONAL_SPACE
```

Trigger

```
ExactValueLiteral(RATIONAL_SPACE, (True,))
```

Valid recovery or diagnostic control

```
x = ExactValueLiteral(RATIONAL_SPACE, (Fraction(1, 10),))
assert x.entries == (Fraction(1, 10),)
```

Observed explicit source site(s): `XI-R1276` at `expression/model.py:39`.

Implementation lookup: `komorebi_math.expression.model._fraction`, `komorebi_math.expression.model.ExactValueLiteral`. **Executed receipt:** `diagnostic_replay/XI-D018/receipt.json`. Its hash is `265f248be52f0004437b8253720a29e0f61cd113492cf0307dac04bad5f50eab`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D019 / Conditional wrapper given a different status

Meaning. The wrapper checks status membership, not a theorem witness.

Recovery decision. Use the correct result type and retain unproved hypotheses instead of relabeling them.

Evidence mode: native finite input. **Observed exception:** `builtins.ValueError`. Expected message fragment: `conditional certificate`.

Setup

```
from komorebi_math.certificates import Certificate, Exactness, ConditionalResult
from komorebi_math.expression.certification import compose_certificates
```

Trigger

```
ConditionalResult(7, Certificate(True, Exactness.EXACT))
```

Valid recovery or diagnostic control

```
r = ConditionalResult(7, Certificate(True, Exactness.CONDITIONAL, assumptions_unchecked=('H',)))
assert r.certificate.exactness is Exactness.CONDITIONAL
```

Observed explicit source site(s): `XI-R0335` at `certificates.py:86`.

Implementation lookup: `komorebi_math.certificates.ConditionalResult`. **Executed receipt:** `diagnostic_replay/XI-D019/receipt.json`. Its hash is `9ef6f60afeb4b88cb3f862a800f43324bd0e3780edc41a082a15c8a544b3b049`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D020 / Nonfinite residual in certificate composition

Meaning. The composition layer refuses a nonfinite residual.

Recovery decision. Trace the numerical or producer failure rather than replacing a NaN with a fabricated passing residual. The zero example is an independent valid input.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `finite`.

Setup

```
from komorebi_math.certificates import Certificate, Exactness, ConditionalResult
from komorebi_math.expression.certification import compose_certificates
```

Trigger

```
compose_certificates([Certificate(True, Exactness.EXACT, residuals={'r': float('nan')})])
```

Valid recovery or diagnostic control

```
c = compose_certificates([Certificate(True, Exactness.EXACT, residuals={'r': 0.0})])
assert c.valid
```

Observed explicit source site(s): `XI-R1157` at `expression/certification.py:86`.

Implementation lookup: `komorebi_math.expression.certification._finite_float`. **Executed receipt:** `diagnostic_replay/XI-D020/receipt.json`. Its hash is `a8787f4728f6eada689cb75ce9b8935ae35dc07d1f94db1bf3fa7a96ebcfa6c6`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D021 / Numerical status without ExactnessError

Meaning. A successful numerical computation does not automatically raise ExactnessError when the caller hoped for exactness.

Recovery decision. Inspect the result evidence class and select a genuinely exact route when required.

Evidence mode: native finite input. No immediate exception is required. Observed fields: `{"exactness": "numerical", "valid": true}`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
from komorebi_math.certificates import Exactness
```

Trigger

```
c = PacketSystem([np.eye(2)]).certificate()
assert c.valid and c.exactness is Exactness.NUMERICAL
observation = {'valid': bool(c.valid), 'exactness': c.exactness.value}
```

Valid recovery or diagnostic control

```
assert c.exactness is not Exactness.EXACT
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.core.packets.PacketSystem.certificate`, `komorebi_math.exceptions.ExactnessError`. **Executed receipt:** `diagnostic_replay/XI-D021/receipt.json`. Its hash is `75f4c5cdd2b643eb659935dc8726a1971b1e39f3f930d1eddd6d565a2ea81b4f`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Failed assumptions

XI-D022 / Negative prior mass

Meaning. Input probability mass must be finite and nonnegative.

Recovery decision. Reconcile the likelihood, state space and prior from the actual model. Do not add unsupported mass solely to pass the check.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `nonnegative`.

Setup

```
from komorebi_math.dynamics.bayes import BayesianUpdate
import numpy as np
```

Trigger

```
BayesianUpdate([-1, 2], [1, 1])
```

Valid recovery or diagnostic control

```
u = BayesianUpdate([0.5, 0.5], [1, 2])
assert np.allclose(u.posterior, [1 / 3, 2 / 3])
```

Observed explicit source site(s): `XI-R0906` at `dynamics/bayes.py:21`.

Implementation lookup: `komorebi_math.dynamics.bayes.BayesianUpdate`, `komorebi_math.dynamics.bayes._probability`, `komorebi_math.dynamics.bayes._likelihood`. **Executed receipt:** `diagnostic_replay/XI-D022/receipt.json`. Its hash is `be958a22ff31d659bc9a8f09bbce1328dab0a53c0e6cc83cf34d2876dbf9cf1f`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D023 / Zero evidence despite nonzero likelihood

Meaning. The likelihood is nonzero only where the prior is zero. Construction is possible; evaluating posterior enforces positive evidence.

Recovery decision. Reconcile the likelihood, state space and prior from the actual model. Do not add unsupported mass solely to pass the check.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.AssumptionError`. Expected message fragment: `zero evidence`.

Setup

```
from komorebi_math.dynamics.bayes import BayesianUpdate
import numpy as np
```

Trigger

```
BayesianUpdate([1, 0], [0, 1]).posterior
```

Valid recovery or diagnostic control

```
u = BayesianUpdate([0.5, 0.5], [1, 2])
assert np.allclose(u.posterior, [1 / 3, 2 / 3])
```

Observed explicit source site(s): `XI-R0912` at `dynamics/bayes.py:78`.

Implementation lookup: `komorebi_math.dynamics.bayes.BayesianUpdate`, `komorebi_math.dynamics.bayes._probability`, `komorebi_math.dynamics.bayes._likelihood`. **Executed receipt:** `diagnostic_replay/XI-D023/receipt.json`. Its hash is

`99dc3d089cacb780408165e77fffcfc372e215291ef217f74ab930b7e9946714`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D024 / Likelihood dimension mismatch

Meaning. Likelihood and prior must refer to the same state space.

Recovery decision. Reconcile the likelihood, state space and prior from the actual model. Do not add unsupported mass solely to pass the check.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.DimensionError`. Expected message fragment: `dimension`.

Setup

```
from komorebi_math.dynamics.bayes import BayesianUpdate
import numpy as np
```

Trigger

```
BayesianUpdate([0.5, 0.5], [1])
```

Valid recovery or diagnostic control

```
u = BayesianUpdate([0.5, 0.5], [1, 2])
assert np.allclose(u.posterior, [1 / 3, 2 / 3])
```

Observed explicit source site(s): `XI-R0908` at `dynamics/bayes.py:31`.

Implementation lookup: `komorebi_math.dynamics.bayes.BayesianUpdate`, `komorebi_math.dynamics.bayes._probability`, `komorebi_math.dynamics.bayes._likelihood`. **Executed receipt:** `diagnostic_replay/XI-D024/receipt.json`. Its hash is `25fb13ed46caec70cdd6c000ddddfab6e7b7e5794383c22bbe5527bbfeb0ca69`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D025 / All-zero likelihood

Meaning. The constructor rejects an everywhere-zero likelihood before posterior evaluation.

Recovery decision. Reconcile the likelihood, state space and prior from the actual model. Do not add unsupported mass solely to pass the check.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `positive on at least one`.

Setup

```
from komorebi_math.dynamics.bayes import BayesianUpdate
import numpy as np
```

Trigger

```
BayesianUpdate([0.5, 0.5], [0, 0])
```

Valid recovery or diagnostic control

```
u = BayesianUpdate([0.5, 0.5], [1, 2])
assert np.allclose(u.posterior, [1 / 3, 2 / 3])
```

Observed explicit source site(s): `XI-R0910` at `dynamics/bayes.py:35`.

Implementation lookup: `komorebi_math.dynamics.bayes.BayesianUpdate`, `komorebi_math.dynamics.bayes._probability`, `komorebi_math.dynamics.bayes._likelihood`. **Executed receipt:** `diagnostic_replay/XI-D025/receipt.json`. Its hash is

`2db8a7cfcc3f88f8ca2c4ec999fbe612bb82ee65d0f0449a1fe1c60c2f1c0a70`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Resource refusal

XI-D026 / Budget refusal: maximum_degree

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_degree`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_degree=4)
```

Trigger

```
b.require_degree(5)
```

Valid recovery or diagnostic control

```
assert b.require_degree(4) == 4
```

Observed explicit source site(s): `XI-R1526` at `generating/budget.py:52`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_degree`. **Executed receipt:** `diagnostic_replay/XI-D026/receipt.json`. Its hash is `ccde16281aa5affffbfd2aa71b1f9ec48fae119def7b1c1bd486af82b04ad7c4`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D027 / Budget refusal: maximum_local_combinations

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_local_combinations`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_local_combinations=4)
```

Trigger

```
b.require_terms(5)
```

Valid recovery or diagnostic control

```
assert b.require_terms(4) == 4
```

Observed explicit source site(s): `XI-R1528` at `generating/budget.py:64`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_terms`. **Executed receipt:** `diagnostic_replay/XI-D027/receipt.json`. Its hash is `b67accf1f331f622b1232f688f9198eb592e5ec00394e38272e96a47caf32158`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D028 / Budget refusal: maximum_matrix_dimension

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_matrix_dimension`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_matrix_dimension=4)
```

Trigger

```
b.require_matrix_dimension(5)
```

Valid recovery or diagnostic control

```
assert b.require_matrix_dimension(4) == 4
```

Observed explicit source site(s): `XI-R1529` at `generating/budget.py:81`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_matrix_dimension`. **Executed receipt:** `diagnostic_replay/XI-D028/receipt.json`. Its hash is `050fed0bd969dd0d2e3245126d97371a241c64f7e786596da5a02ba5bfdcc332`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D029 / Budget refusal: maximum_reachable_states

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_reachable_states`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_reachable_states=4)
```

Trigger

```
b.require_states(5)
```

Valid recovery or diagnostic control

```
assert b.require_states(4) == 4
```

Observed explicit source site(s): `XI-R1530` at `generating/budget.py:92`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_states`. **Executed receipt:** `diagnostic_replay/XI-D029/receipt.json`. Its hash is `448519ba87a85f93b611d082a7d1239eaf53ff45c3d55f274adda2ad25fb1d74`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D030 / Budget refusal: maximum_local_combinations

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_local_combinations`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_local_combinations=4)
```

Trigger

```
b.require_local_combinations(5)
```

Valid recovery or diagnostic control

```
assert b.require_local_combinations(4) == 4
```

Observed explicit source site(s): `XI-R1531` at `generating/budget.py:103`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_local_combinations`. **Executed receipt:** `diagnostic_replay/XI-D030/receipt.json`. Its hash is `7b0362cf51b3ecaa60198e65be854855066fccc53f3a618a7f88c1e7401ea10f`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D031 / Budget refusal: maximum_modulus

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_modulus`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_modulus=4)
```

Trigger

```
b.require_modulus(5)
```

Valid recovery or diagnostic control

```
assert b.require_modulus(4) == 4
```

Observed explicit source site(s): `XI-R1532` at `generating/budget.py:114`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_modulus`. **Executed receipt:** `diagnostic_replay/XI-D031/receipt.json`. Its hash is `f0e7defdf230501571b6a900470c9ef93519c791042116b129184d48131cec73`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D032 / Budget refusal: maximum_serialized_bytes

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_serialized_bytes`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_serialized_bytes=4)
```

Trigger

```
b.require_serialized_bytes(5)
```

Valid recovery or diagnostic control

```
assert b.require_serialized_bytes(4) == 4
```

Observed explicit source site(s): `XI-R1534` at `generating/budget.py:125`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_serialized_bytes`. **Executed receipt:** `diagnostic_replay/XI-D032/receipt.json`. Its hash is `62475796e4e28dad65f1562576675faf2981e36c27285ee109b8942be65e6095`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D033 / Budget refusal: maximum_coefficient_bits

Meaning. The explicit request exceeds this local budget field before the guarded work.

Recovery decision. Reduce the requested work or justify a measured larger limit. A larger cap is not evidence that memory is available.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ResourceLimitError`. Expected message fragment: `maximum_coefficient_bits`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget(maximum_coefficient_bits=4)
```

Trigger

```
b.require_coefficient_bits(5)
```

Valid recovery or diagnostic control

```
assert b.require_coefficient_bits(4) == 4
```

Observed explicit source site(s): `XI-R1536` at `generating/budget.py:137`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_coefficient_bits`. **Executed receipt:** `diagnostic_replay/XI-D033/receipt.json`. Its hash is `c987ecb4ced07d7beb1bba4a0d29584144bbc0d9741131bc15ca5ff238e22952`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D034 / Boolean is not a truncation degree

Meaning. The budget route deliberately excludes bool even though it is an int subclass.

Recovery decision. Pass an explicit nonnegative integer request.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `nonnegative integer`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
b = GeneratingBudget()
```

Trigger

```
b.require_degree(True)
```

Valid recovery or diagnostic control

```
assert b.require_degree(0) == 0
```

Observed explicit source site(s): `XI-R1525` at `generating/budget.py:50`.

Implementation lookup: `komorebi_math.generating.budget.GeneratingBudget.require_degree`. **Executed receipt:** `diagnostic_replay/XI-D034/receipt.json`. Its hash is `1f303ce5e4947f2d5fb0d3b51b9c422c2eb1510dac20488050c179c5a2a80422`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D035 / Invalid budget declaration

Meaning. Limit fields must be positive integers.

Recovery decision. Set a positive bound. A zero request and a zero configured ceiling are different contracts.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `positive integer`.

Setup

```
from komorebi_math.generating.budget import GeneratingBudget
```

Trigger

```
GeneratingBudget(maximum_degree=0)
```

Valid recovery or diagnostic control

```
assert GeneratingBudget(maximum_degree=4).maximum_degree == 4
```

Observed explicit source site(s): `XI-R1524` at `generating/budget.py:12`.

Implementation lookup: `komorebi_math.generating.budget._positive`. **Executed receipt:** `diagnostic_replay/XI-D035/receipt.json`. Its hash is `84754ec75029a59751d82b18a6e853f973c5dc359aaccb59b02849ba80df299d`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Planned feature

XI-D036 / Declared planned feature (controlled registry fixture)

Meaning. The reserved-namespace guard raises for a controlled planned registry entry. No existing feature is claimed to be planned in R2.

Recovery decision. Use an implemented capability or leave the task unavailable. Changing fixture metadata exercises the guard only; it does not implement a real feature.

Evidence mode: synthetic registry entry in a fresh child process. **Observed exception:** `komorebi_math.exceptions.FeatureNotImplementedError`. Expected message fragment: `declared as planned`.

Setup

```
from komorebi_math.registry import FeatureSpec, FeatureStatus, register_feature
from komorebi_math._planned import require_implemented
register_feature(FeatureSpec('block41-demo', 'example.namespace', 'Controlled planned feature',
    ↪  FeatureStatus.PLANNED, 'test fixture'))
```

Trigger

```
require_implemented('block41-demo')
```

Valid recovery or diagnostic control

```
register_feature(FeatureSpec('block41-demo', 'example.namespace', 'Controlled implemented fixture',
    ↪  FeatureStatus.IMPLEMENTED, 'test fixture'), replace=True)
assert require_implemented('block41-demo') is None
```

Observed explicit source site(s): `XI-R0004` at `_planned.py:17`.

Implementation lookup: `komorebi_math._planned.require_implemented`. **Executed receipt:** `diagnostic_replay/XI-D036/receipt.json`. Its hash is `958e42c960e557adac172616012b432e189526211f952c30e0cd5503694d2220`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Persistence, schema and tamper failure

XI-D037 / Malformed JSON

Meaning. The JSON parser failure is wrapped as ValidationError with its cause.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `valid UTF-8 JSON`. **Explicit cause:** `json.decoder.JSONDecodeError`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
loads_portable('{')
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1116` at `export/persistence.py:805`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D037/receipt.json`. Its hash is `04f6926a86370fe19b8e6e6b7e5adb8e756022c0311eac53f0ac5653f157bdc0`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D038 / Invalid UTF-8

Meaning. Byte decoding fails before portable envelope validation.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `valid UTF-8 JSON`. **Explicit cause:** `builtins.UnicodeDecodeError`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
loads_portable(b'\xff')
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1116` at `export/persistence.py:805`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D038/receipt.json`. Its hash is `76df98947003d3f7fb862ef52ac02146e96e2e758f4434bc2fb5a284b32967bd`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D039 / Duplicate JSON object key

Meaning. Duplicate keys are rejected before envelope comparison.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `duplicate object key`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
loads_portable('{"x":1,"x":2}')
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1076` at `export/persistence.py:509`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D039/receipt.json`. Its hash is `3c7a169658b858983b8e38a5bf9026ec91c0ef8bb8f0633d8723824755b62a9b`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D040 / Nonfinite JSON constant

Meaning. Nonstandard nonfinite numeric tokens are rejected.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `nonfinite constant`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
loads_portable('{"x":NaN}')
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1077` at `export/persistence.py:517`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D040/receipt.json`. Its hash is `be19394b3a81984ebc9fc535be6b10693c682c124b7c114ab6550b268368e508`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D041 / Missing envelope field

Meaning. Every required outer field must be present.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `fields do not match`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
e = json.loads(good)
e.pop('producer_version')
```

Trigger

```
loads_portable(json.dumps(e))
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1118` at `export/persistence.py:810`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D041/receipt.json`. Its hash is `e311b01f44d27334eb2a2e6ce817bc09d94d188b34f0d9483bc7d3f8454a13b9`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D042 / Unknown outer schema

Meaning. The outer schema identifies the decoding contract.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `unknown schema`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
e = json.loads(good)
e['schema'] = 'other'
```

Trigger

```
loads_portable(json.dumps(e))
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1119` at `export/persistence.py:812`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D042/receipt.json`. Its hash is `58bd00880133b40b4404cbf6378fe09b8c81b99c910643f467b14fee04a08dba`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D043 / Unsupported outer version

Meaning. This reader does not advertise arbitrary forward compatibility.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `version is unsupported`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
e = json.loads(good)
e['schema_version'] = 99
```

Trigger

```
loads_portable(json.dumps(e))
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1120` at `export/persistence.py:814`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D043/receipt.json`. Its hash is `dc93356969cba0e6767effd19fd8104845e4d35ac0383ab888592bb239719070`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D044 / Payload checksum mismatch

Meaning. The decoded payload no longer matches its recorded digest.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `SHA256 mismatch`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
e = json.loads(good)
e['payload'] = 123
```

Trigger

```
loads_portable(json.dumps(e))
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1122` at `export/persistence.py:823`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D044/receipt.json`. Its hash is `38df18d64ee4bbf4cf4434e89c41f0b7dc39da4c6615ca9bc1f1c02759e880b3`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D045 / Unknown portable tag

Meaning. Low-level tagged decoding rejects an unregistered tag.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `unknown portable codec`. **Explicit cause:** `builtins.KeyError`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
from_portable_data({'__komorebi_type__': 'missing.tag', '__version__': 1, 'data': {}})
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1113` at `export/persistence.py:735`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D045/receipt.json`. Its hash is `30cff219e5e2db50294fde3b8df32c15f87f59589f0cbd018fdec3f6ee9da5c9`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D046 / Unsupported future codec version

Meaning. A supported type is not permission to accept unknown versions.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `unsupported Fraction codec version`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
d = to_portable_data(Fraction(1, 3))
d['__version__'] = 99
```

Trigger

```
from_portable_data(d)
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1086` at `export/persistence.py:639`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D046/receipt.json`. Its hash is `be014735a817e304a5f0fbc6ccacf4b7782488ec6656ad6934102a0cc6e04cb8`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D047 / Invalid rational denominator

Meaning. Rational reconstruction rejects a zero denominator and preserves its cause.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `Fraction data is invalid`. **Explicit cause:** `builtins.ZeroDivisionError`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
d = to_portable_data(Fraction(1, 3))
d['data']['denominator'] = 0
```

Trigger

```
from_portable_data(d)
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1088` at `export/persistence.py:645`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D047/receipt.json`. Its hash is `f1edd884252ae290d77de13ec2566ab823697f61137169bbade6451dd093f78d`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D048 / Serialization depth exceeded

Meaning. The local recursion limit is checked by the encoder.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `serialization depth exceeded`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
to_portable_data([[[1]]], max_depth=1)
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1078` at `export/persistence.py:522`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D048/receipt.json`. Its hash is `5ea3ea69112e3df0599c82e6f96e612fc3bcc494d2db804f1818681d6b643dd4`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D049 / Deserialization depth exceeded

Meaning. The decoder rejects the nested tree at its local depth limit.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `deserialization depth exceeded`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
from_portable_data([[[1]]], max_depth=1)
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1082` at `export/persistence.py:614`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D049/receipt.json`. Its hash is `43bb8d56f5e4bff16f232502517bd5351da31abfc179373bc613e100d36d8e7a`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D050 / Nonfinite float serialization

Meaning. The writer refuses nonfinite scalar values.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `nonfinite floats`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
to_portable_data(float('nan'))
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1079` at `export/persistence.py:537`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D050/receipt.json`. Its hash is `71b024d24d7e6dfeb981ec7b1d9778e250a59fada145dbf5d200fc0322585fb4`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D051 / Unregistered object serialization

Meaning. Only supported values and explicitly registered codecs are encoded.

Recovery decision. Keep the failing artifact for diagnosis. Restore or regenerate from a trusted producer and supported schema; do not patch a digest merely to conceal corruption. The successful control uses the unchanged valid envelope.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `portable`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪ save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
to_portable_data(object())
```

Valid recovery or diagnostic control

```
assert loads_portable(good) == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1081` at `export/persistence.py:607`.

Implementation lookup: `komorebi_math.export.persistence`. **Executed receipt:** `diagnostic_replay/XI-D051/receipt.json`. Its hash is `1f55aa5f66b856d76bf73c68e7ad707e731a81321111acf5a786cec70b1bf708`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D052 / Portable file cannot be read

Meaning. File I/O errors are translated to ValidationError and retain an OSError cause.

Recovery decision. Check the actual path and read permissions, retaining the cause. A parse fix will not repair a missing file.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `could not read`. **Explicit cause:** `builtins.FileNotFoundError`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪ save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
```

Trigger

```
load_portable(work / 'missing.json')
```

Valid recovery or diagnostic control

```
save_portable(Fraction(1, 3), work / 'valid.json')
assert load_portable(work / 'valid.json') == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1125` at `export/persistence.py:867`.

Implementation lookup: `komorebi_math.export.persistence.load_portable`. **Executed receipt:** `diagnostic_replay/XI-D052/receipt.json`. Its hash is `7b6bf722a83bdca62cb880444bc86f7e47efe79f029f694a70f380d2bcc6a9b7`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D053 / Protected portable destination

Meaning. The existing file is protected before encoding and replacement.

Recovery decision. Choose a new destination, or make an explicit reviewed overwrite decision after preserving the old file.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `refusing to overwrite`.

Setup

```
import json
from fractions import Fraction
from komorebi_math.export.persistence import dumps_portable, loads_portable, to_portable_data, from_portable_data,
    ↪  save_portable, load_portable
good = dumps_portable(Fraction(1, 3))
p = work / 'existing.json'
p.write_text('sentinel')
```

Trigger

```
save_portable(Fraction(1, 3), p)
```

Valid recovery or diagnostic control

```
assert p.read_text() == 'sentinel'
save_portable(Fraction(1, 3), work / 'new.json')
assert load_portable(work / 'new.json') == Fraction(1, 3)
```

Observed explicit source site(s): `XI-R1123` at `export/persistence.py:839`.

Implementation lookup: `komorebi_math.export.persistence.save_portable`. **Executed receipt:** `diagnostic_replay/XI-D053/receipt.json`. Its hash is `d0b54ee586b6ebb827cfe7b6ed0ef647f95db2bcdc493b10a2d98a43f096c8ad`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Export, compiler and path failure

XI-D054 / Unknown export suffix

Meaning. The suffix has no implicit format mapping.

Recovery decision. Use a supported suffix or explicitly choose a supported format.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `cannot infer`. **Explicit cause:** `builtins.KeyError`.

Setup

```
from komorebi_math.export import export_data, ExportOptions
import json
```

Trigger

```
export_data([1, 2], work / 'result.unknown')
```

Valid recovery or diagnostic control

```
r = export_data([1, 2], work / 'result.json')
assert r.require().is_file()
```

Observed explicit source site(s): `XI-R1141` at `export/writers.py:160`.

Implementation lookup: `komorebi_math.export.writers.infer_export_format`. **Executed receipt:** `diagnostic_replay/XI-D054/receipt.json`. Its hash is `5908c6528497adc5d452b05597c8df67d34619bead268d5688a6f110110ef885`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D055 / Unknown explicit export format

Meaning. The format enum raises ordinary ValueError rather than ValidationError.

Recovery decision. Check format names separately from path permissions and mathematical data.

Evidence mode: native finite input. **Observed exception:** `builtins.ValueError`. Expected message fragment: `not-a-format`.

Setup

```
from komorebi_math.export import export_data, ExportOptions
import json
```

Trigger

```
export_data([1, 2], work / 'result.json', format='not-a-format')
```

Valid recovery or diagnostic control

```
r = export_data([1, 2], work / 'result.json', format='json')
assert r.valid
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.export.writers._resolve_format`. **Executed receipt:** `diagnostic_replay/XI-D055/receipt.json`. Its hash is `64417ebc670575e3ecc82ff671164164a6c65a79a9cc5b385323fd30548bd4a4`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D056 / Protected ordinary export destination

Meaning. The writer refuses replacement without explicit permission.

Recovery decision. Prefer a new output path; use overwrite only after review.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `already exists`.

Setup

```
from komorebi_math.export import export_data, ExportOptions
import json
p = work / 'existing.json'
p.write_text('sentinel')
```

Trigger

```
export_data([1, 2], p)
```

Valid recovery or diagnostic control

```
assert p.read_text() == 'sentinel'
r = export_data([1, 2], work / 'new.json')
assert r.valid
```

Observed explicit source site(s): `XI-R1142` at `export/writers.py:176`.

Implementation lookup: `komorebi_math.export.writers._prepare_path`. **Executed receipt:** `diagnostic_replay/XI-D056/receipt.json`. Its hash is `09c2ec07ed9afd7769b844826def33955393c280f187fe525dd43656f5a6df74`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D057 / Parent directory absent with creation disabled

Meaning. The requested create_parents=False contract forbids implicit creation.

Recovery decision. Create the intended parent or explicitly enable creation.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `parent directory does not exist`.

Setup

```
from komorebi_math.export import export_data, ExportOptions
import json
```

Trigger

```
export_data([1], work / 'absent' / 'value.json', options=ExportOptions(create_parents=False))
```

Valid recovery or diagnostic control

```
r = export_data([1], work / 'created' / 'value.json')
assert r.valid
```

Observed explicit source site(s): `XI-R1143` at `export/writers.py:180`.

Implementation lookup: `komorebi_math.export.writers._prepare_path`. **Executed receipt:** `diagnostic_replay/XI-D057/receipt.json`. Its hash is `d1f7c7c69339341e9312f5af90b75ee6a5a02ca287631dcd514e525c806f2c74`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D058 / Invalid compiler pass count

Meaning. No zero-pass compilation is defined.

Recovery decision. Choose a positive bounded pass count.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `passes must be positive`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
```

Trigger

```
LatexCompileOptions(passes=0)
```

Valid recovery or diagnostic control

```
assert LatexCompileOptions(passes=1).passes == 1
```

Observed explicit source site(s): `XI-R1044` at `export/latex.py:42`.

Implementation lookup: `komorebi_math.export.latex.LatexCompileOptions`. **Executed receipt:** `diagnostic_replay/XI-D058/receipt.json`. Its hash is `c5e04783b0797e013a2ebad505d2f1a59732de4241be8bce0a2df4d5ecde1935`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D059 / Invalid compiler time limit

Meaning. Compilation requires a positive timeout value.

Recovery decision. Choose a finite operational budget and inspect failure logs rather than repeating without bounds.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `timeout must be positive`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
```

Trigger

```
LatexCompileOptions(timeout=0)
```

Valid recovery or diagnostic control

```
assert LatexCompileOptions(timeout=5).timeout == 5
```

Observed explicit source site(s): `XI-R1045` at `export/latex.py:44`.

Implementation lookup: `komorebi_math.export.latex.LatexCompileOptions`. **Executed receipt:** `diagnostic_replay/XI-D059/receipt.json`. Its hash is `13a2aa78ba394cbf183dd446f9e4a13c61ac88e245fb13ea08103938d759e4b1`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D060 / Unsafe compiler job name

Meaning. Job names cannot contain path separators.

Recovery decision. Use a simple basename and control the output directory separately.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `simple file name`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
```

Trigger

```
LatexCompileOptions(jobname='../escape')
```

Valid recovery or diagnostic control

```
assert LatexCompileOptions(jobname='report').jobname == 'report'
```

Observed explicit source site(s): `XI-R1046` at `export/latex.py:47`.

Implementation lookup: `komorebi_math.export.latex.LatexCompileOptions`. **Executed receipt:** `diagnostic_replay/XI-D060/receipt.json`. Its hash is `2ffed8ebef58d7e9c48231888eee23fcc3a0668aaa21b31259268999621c337d`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D061 / Missing compiler (controlled PATH discovery)

Meaning. The discovery refusal is exercised with a controlled unavailable engine.

Recovery decision. Resolve a real compiler before invoking it. Constructing options alone does not establish availability.

Evidence mode: mocked compiler discovery, not native absence. **Observed exception:** `komorebi_math.exceptions.BackendUnavailableError`. Expected message fragment: `not installed`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
from unittest.mock import patch
```

Trigger

```
with patch('komorebi_math.export.latex.shutil.which', return_value=None):
    resolve_latex_engine('pdflatex')
```

Valid recovery or diagnostic control

```
assert LatexCompileOptions(engine='pdflatex').engine.value == 'pdflatex'
```

Observed explicit source site(s): `XI-R1048` at `export/latex.py:87`.

Implementation lookup: `komorebi_math.export.latex.resolve_latex_engine`. **Executed receipt:** `diagnostic_replay/XI-D061/receipt.json`. Its hash is `94d17393ad54ba1bbd13f717062bc370bc44a78c721a5691e540306065edd301`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D062 / Missing LaTeX Path object

Meaning. After engine resolution, an explicit Path must point to a file. A nonexistent .tex string is instead treated as literal TeX by this implementation.

Recovery decision. Use a Path for an existing source file and validate it before compiling.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `source file does not exist`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
```

Trigger

```
compile_latex(work / 'missing.tex', work / 'out', options=LatexCompileOptions(engine='pdflatex', passes=1))
```

Valid recovery or diagnostic control

```
p = work / 'actual.tex'
p.write_text('\\documentclass{article}\\begin{document}Valid fixture\\end{document}')
r = compile_latex(p, work / 'valid', options=LatexCompileOptions(engine='pdflatex', passes=1))
assert r.require().is_file()
```

Observed explicit source site(s): `XI-R1050` at `export/latex.py:166`.

Implementation lookup: `komorebi_math.export.latex.compile_latex`. **Executed receipt:** `diagnostic_replay/XI-D062/receipt.json`. Its hash is `9b46db700f71773653260b64b1370ff93c4270605bc8fcde3cbda6d1fefd97e2`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D063 / Compiler failure is a returned negative result

Meaning. A compiler nonzero exit returns a LatexCompilation with a false certificate, rather than raising immediately.

Recovery decision. Inspect valid, return_codes and the retained compiler log. Require success before publishing or consuming the PDF.

Evidence mode: native finite input. No immediate exception is required. Observed fields: `{"log_exists": true, "return_codes": [1], "valid": false}`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
```

Trigger

```
r = compile_latex('\\documentclass{article}\\begin{document}\\unknownBlockFortyOneCommand\\end{document}', work /
    ↪  'bad', options=LatexCompileOptions(engine='pdflatex', passes=1))
assert not r.valid
observation = {'valid': r.valid, 'return_codes': list(r.return_codes), 'log_exists': r.log_path.is_file()}
```

Valid recovery or diagnostic control

```
r.certificate.valid is False
try:
    r.require()
except Exception as exc:
    assert type(exc).__name__ == 'ValidationError'
else:
    raise AssertionError('negative compiler certificate admitted')
s = compile_latex('\\documentclass{article}\\begin{document}Repaired fixture\\end{document}', work / 'good',
    ↪  options=LatexCompileOptions(engine='pdflatex', passes=1))
assert s.require().is_file()
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.export.latex.compile_latex`, `komorebi_math.export.latex.LatexCompilation.require`. **Executed receipt:** `diagnostic_replay/XI-D063/receipt.json`. Its hash is `2124fd3abe7110714e0f342d92d367b13ba28f087f3677e1bdca858bf016ed6b`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D064 / Compiler timeout (controlled subprocess)

Meaning. The wrapper converts TimeoutExpired into return code 124 and a negative certificate.

Recovery decision. Keep timeout and compiler diagnostics separate from an invalid mathematical input. Retry only after fixing complexity, resources or the timeout rationale.

Evidence mode: mocked subprocess timeout; no real hanging compiler. No immediate exception is required. Observed fields: `{"return_codes": [124], "valid": false}`.

Setup

```
from pathlib import Path
from komorebi_math.export.latex import LatexCompileOptions, compile_latex, resolve_latex_engine
import subprocess
from unittest.mock import patch
```

Trigger

```
with patch('komorebi_math.export.latex.subprocess.run', side_effect=subprocess.TimeoutExpired(['pdflatex'], 1)):
    r = compile_latex('fixture', work / 'timed', options=LatexCompileOptions(engine='pdflatex', passes=1))
assert not r.valid and r.return_codes == (124,)
observation = {'valid': r.valid, 'return_codes': list(r.return_codes)}
```

Valid recovery or diagnostic control

```
assert 'timed out' in r.log_path.read_text()
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.export.latex.compile_latex`. **Executed receipt:** `diagnostic_replay/XI-D064/receipt.json`. Its hash is `78f99e2b74ea0aa05d14896b21c5ab7173a7823f3691e26c822c4aa70525815e`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Warnings

XI-D065 / Deprecation warning without function failure

Meaning. Warnings have a distinct control channel and the wrapped function still runs. Capture the package warning category explicitly.

Recovery decision. Plan migration to the documented replacement. Avoid turning all warnings off as a repair.

Evidence mode: native finite input. No immediate exception is required. Observed fields: `{"category": "KomorebiDeprecationWarning", "message": "old_api is deprecated since 1.0; use new_api instead", "value": 7}`.

Setup

```
import warnings
from komorebi_math.compatibility import deprecated, KomorebiDeprecationWarning

@deprecated(since='1.0', replacement='new_api')
def old_api():
    return 7
```

Trigger

```
with warnings.catch_warnings(record=True) as seen:
    warnings.simplefilter('always', KomorebiDeprecationWarning)
    value = old_api()
assert value == 7 and len(seen) == 1 and (seen[0].category is KomorebiDeprecationWarning)
observation = {'category': seen[0].category.__name__, 'message': str(seen[0].message), 'value': value}
```

Valid recovery or diagnostic control

```
assert 'new_api' in str(seen[0].message)
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.compatibility.warn_deprecated`, `komorebi_math.compatibility.deprecated`. **Executed receipt:** `diagnostic_replay/XI-D065/receipt.json`. Its hash is `4bfbb554cda1eabdb63aea373d06c34fc1c19421463c8002daca644e7a728cc8`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D066 / Warnings promoted to errors

Meaning. A warning filter can turn the same call into a raised warning exception.

Recovery decision. Distinguish a chosen warning policy from a mathematical computation failure; migrate the deprecated call.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.compatibility.KomorebiDeprecationWarning`. Expected message fragment: `new_api`.

Setup

```
import warnings
from komorebi_math.compatibility import deprecated, KomorebiDeprecationWarning

@deprecated(since='1.0', replacement='new_api')
def old_api():
    return 7
```

Trigger

```
with warnings.catch_warnings():
    warnings.simplefilter('error', KomorebiDeprecationWarning)
    old_api()
```

Valid recovery or diagnostic control

```
with warnings.catch_warnings(record=True) as seen:
    warnings.simplefilter('always', KomorebiDeprecationWarning)
    assert old_api() == 7
assert len(seen) == 1
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.compatibility.warn_deprecated`. **Executed receipt:** `diagnostic_replay/XI-D066/receipt.json`. Its hash is `c7e44131b4ca58bd26afb01c044b8ebdfb19b434224e2043cb314b0684dc104b`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Returned certificates

XI-D067 / Negative stored certificate

Meaning. require raises only because the stored flag is false. The positive control is not a repair of an invalid mathematical witness.

Recovery decision. Inspect the original producer, residuals and assumptions. Never edit valid=True as a substitute for fixing the producer.

Evidence mode: native finite input. **Observed exception:** `komorebi_math.exceptions.ValidationError`. Expected message fragment: `fixture failed`.

Setup

```
from komorebi_math.certificates import Certificate, Exactness, ConditionalResult
from komorebi_math.expression.certification import compose_certificates
```

Trigger

```
Certificate(False, Exactness.NUMERICAL, message='fixture failed').require()
```

Valid recovery or diagnostic control

```
c = Certificate(True, Exactness.NUMERICAL, message='independent positive control')
assert c.require() is c
```

Observed explicit source site(s): `XI-R0334` at `certificates.py:45`.

Implementation lookup: `komorebi_math.certificates.Certificate.require`. **Executed receipt:** `diagnostic_replay/XI-D067/receipt.json`. Its hash is `84c3092591a4abaf1eb74b69d4bd7203f72a06b80780a6553e1ac10774dedf69`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D068 / Bypassed packet axioms are not repaired by Hilbert status

Meaning. A previously documented producer boundary is reproduced. hilbert_certificate does not rerun all packet axioms after construction validation was bypassed.

Recovery decision. Require the base packet-axiom certificate as well as any specialized certificate. Do not use the favorable specialized flag to override a failed prerequisite.

Evidence mode: native finite input. No immediate exception is required. Observed fields: `{"hilbert_flag": true, "packet_axioms": false}`.

Setup

```
from komorebi_math import PacketSystem
import numpy as np
```

Trigger

```
p = PacketSystem([2 * np.eye(2)], validate=False)
assert not p.certificate().valid and p.hilbert_certificate().valid
observation = {'packet_axioms': bool(p.certificate().valid), 'hilbert_flag': bool(p.hilbert_certificate().valid)}
```

Valid recovery or diagnostic control

```
q = PacketSystem([np.eye(2)])
assert q.certificate().valid and q.hilbert_certificate().valid
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.core.packets.PacketSystem.hilbert_certificate`, `komorebi_math.core.packets.PacketSystem.certificate`. **Executed receipt:** `diagnostic_replay/XI-D068/receipt.json`. Its hash is `19945b4c88a60b23e8de85b04086936b78f71188e8e63fbc25bfad4a54393cf6`. The source hashes and complete traceback are retained in the crosswalk and receipt.

Cli exit and qualification

XI-D069 / Missing top-level command

Meaning. argparse rejects a missing required command before dispatch.

Recovery decision. Check syntax first; status 2 is not a theorem failure.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 2 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: []
Recovery argv: ["--help"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D069/receipt.json`. Its hash is `fa32e3196f6d84edcabf39985fcdd0c419836912bd54984541e986dd4a994295`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D070 / Unknown verification suite

Meaning. The suite selector is parser-constrained.

Recovery decision. Use the explicit suite list. The all selector is historical, not exhaustive.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 2 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: ["verify", "not-a-suite"]
Recovery argv: ["verify", "stable"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D070/receipt.json`. Its hash is `0484c107f2fc509a769347f5fca8a6267fd641f1f8307f4f6f69d0ff88194538`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D071 / Missing required export destination

Meaning. The required output argument is absent.

Recovery decision. Supply an intended destination after reviewing overwrite policy.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 2 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: ["export", "sequence", "fibonacci"]
Recovery argv: ["export", "formats"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D071/receipt.json`. Its hash is `678d37646295cb2d916846bf8ece195b2cdad110cc7c0e5112375046fdb79302`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D072 / Unknown root version flag

Meaning. There is no global –version flag in the pinned parser.

Recovery decision. Use info or the installed package metadata, rather than assuming a conventional flag exists.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 2 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: ["--version"]
Recovery argv: ["info"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D072/receipt.json`. Its hash is `4ba8e62825c8ee6fe48d804479d8242ed7db71552ff68bb62382f07fe9a42edf`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D073 / Malformed numeric parser argument

Meaning. Argument coercion fails before mathematical validation.

Recovery decision. Supply a correctly typed integer, then check its mathematical admissibility.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 2 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: ["arithmetic", "euler", "--prime", "x", "--index", "2"]
Recovery argv: ["arithmetic", "euler", "--prime", "3", "--index", "2"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D073/receipt.json`. Its hash is `8309af91f6f5909147d42e9895eec044d60dba7dd078bb4da34dc56f1dbaea04`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D074 / Mathematically invalid prime argument

Meaning. A syntactically valid integer fails the handler mathematical contract; the traceback is not wrapped by a universal CLI catch.

Recovery decision. Correct the actual mathematical parameter. Do not relabel a composite as prime.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 1 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: ["arithmetic", "euler", "--prime", "4", "--index", "2"]
Recovery argv: ["arithmetic", "euler", "--prime", "3", "--index", "2"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D074/receipt.json`. Its hash is `c23fd886992603808b05111c1692e4ceffa5ef2999367cbdc34c14d35946c932`. The source hashes and complete traceback are retained in the crosswalk and receipt.

XI-D075 / Unmet completion assumptions

Meaning. The handler emits a negative completion result; this is not a parser failure.

Recovery decision. Inspect the unmet gates. The recovery is navigation only, not a proof that the assumptions hold.

Evidence mode: actual isolated CLI child interpreter. The failure invocation returned 1 and the recovery/navigation invocation returned 0.

Run through `python -I -m komorebi_math` with these argument vectors.

```
Failure argv: ["langlands", "completion"]
Recovery argv: ["--help"]
```

No explicit package raise site is attributed from this recipe's terminal traceback. This is expected for returned observations, warnings emitted through the warning machinery, dependency-only raises and nested CLI processes.

Implementation lookup: `komorebi_math.cli.main.main`. **Executed receipt:** `diagnostic_replay/XI-D075/receipt.json`. Its hash is `f35b74c15ec42ea0620f2e9ef45170a63fa50093b9f99cc295946a19d82c5759`. The source hashes and complete traceback are retained in the crosswalk and receipt.

I.6 Complete electronic site index and module census

The JSON ledger `Block41_Exception_Diagnostic_Index.json` contains all 3408 explicit raise statements, including 6 bare re-raises, 301 handlers, 411 assertions and 1 direct warnings.warn call. The census spans 230 modules containing explicit raises. The remaining source files are still hashed and checked. Column offsets distinguish multiple statements on one source line.

The companion TSV is an exact-message-expression lookup, not an abbreviated sample. Query the inventory by a literal message, exception name, module or owner. For example, from the extracted bundle root:

```
python tools/block41/inventory.py --query "zero evidence"
python tools/block41/inventory.py --query ResourceLimitError --limit 100
```

The lookup reports matching source records and leaves the package unchanged. A dynamic message expression is preserved as source rather than guessed into every possible runtime string. Use a source location and hash together; message text alone is not a stable unique identifier.

Resolved raise expression	Sites
`<reraise>`	6

`numpy.linalg.LinAlgError`	2

The following table covers every module with at least one inventoried diagnostic statement. The complete 300-file hash manifest also includes modules with no such statements. R, C, A and W mean explicit raises, catch clauses, assertions and warning calls. These are syntax counts, not newly proved theorems or dynamically exercised branches.

I.7 Executed outcomes and coverage boundary

Executed check	Result
Unchanged source tests	1,203
Source/index/helper/receipt reference tests	432
Diagnostic recipes and paired controls	75
Recipes expecting an exception	63
Returned-status or warning observations	5
Actual CLI paired recipes	7
Distinct explicit raise sites seen in terminal tracebacks	57
Source raise sites not observed by this finite cookbook	3,351
Observed package-module union in recipe workers	245

All recorded recipe expectations and their recovery/control assertions passed. These are finite examples. A passing negative-case expectation means the refusal happened as specified, not that the denied operation succeeded. The cookbook's unobserved sites may still be exercised by the separate source suite. The source, receipt and recipe counts overlap and must not be added as distinct mathematical coverage totals.

The source and installed package match in all 366 package files, and all 901 library files remain identical to R2. The inherited dependencies are recorded in the environment receipt. Separate installation and origin checks do not establish fully dependency-isolated acceptance.

I.8 Reading handlers and reconstructing a failure chain

The electronic handler ledger records all 301 package `except` clauses. Some translate a dependency failure into a package exception with `raise ... from exc`; some produce a negative result or fall back; others clean up a temporary artifact and re-raise. An empty handler action list means none of the limited syntactic actions was found, not that the handler is harmless or unreachable. Bare re-raises preserve an active exception and do not define an independent error type.

A useful support record names both the final surface exception and its cause. For example, a missing portable file reaches the caller as ValidationError but has a FileNotFoundError cause; an unknown packet name reaches the caller as KeyError with a ValueError cause. The cause is essential for selecting a recovery. The helper `tools/block41/diagnostics.py` retains explicit and unsuppressed implicit chains, stops on cycles, and does not change or suppress the original exception.

For callers that need to log and rethrow, the control pattern is:

```
from diagnostics import exception_record

try:
    result = operation()  # the caller's actual operation
except Exception as exc:
    record = exception_record(exc, include_traceback=True)
    persist_diagnostic(record)  # the caller's reviewed logging implementation
    raise
```

Here `operation` and `persist_diagnostic` are application integration points, not exported Komorebi APIs. A logging failure must not be converted into mathematical success. KeyboardInterrupt and SystemExit are not caught by this pattern. The helper can record them when explicitly supplied, but an application should make interruption handling an intentional policy.

For base certificates, use `certificate_record` to retain exactness, residuals, tolerance, checked and unchecked assumptions, and validity type. It never coerces a truthy string into an actual bool. It also never claims that a favorable stored flag proves the producer was correctly executed. Use the protocol appropriate to specialized certificates rather than passing them through an invented common interface.

I.9 Resource, persistence and compiler boundaries

The eight generating-budget fields are local resource contracts, not a process-wide memory governor. They cover degree, coefficient bits, matrix dimension, reachable states, local combinations, modulus, serialized bytes and recursion depth. The cookbook actively exercises eight public require methods plus invalid declaration/type cases. It does not prove every producer calls every relevant guard. The full site inventory locates the other resource refusals for targeted follow-up.

Portable loading validates a specific schema and detects payload corruption, but successful loading is not proof admission or authenticated origin. Appendix G's permissive field/version conversions, payload-only digest scope, unsupported structured-array behavior and lack of a universal hostile-input budget remain in force. JSON parsing happens before all low-level decoder checks. A user should not treat a stored GeneratingBudget object as a security limit on an arbitrary JSON input.

The LaTeX wrapper resolves an engine before checking the source. When passed a `Path`, it insists on an existing file. A short string ending in `.tex` is treated as a filename only if that path exists; otherwise it becomes literal TeX source. Prefer an explicit Path for files and actual TeX text for in-memory source, rather than relying on that heuristic. Invalid TeX can return a negative compilation record with a log rather than raise. Require the result before treating a produced file as a successful delivery.

The compile route has no general overwrite guard like the ordinary export writers. Use a dedicated output directory for a fresh job and preserve any prior outputs. A favorable filesystem existence check is not a semantic document check. Compiler timeouts, operating-system permissions, unavailable executables and returned negative certificates are separate diagnostic categories.

I.10 Reproduction and completion boundary

Run `inventory.py` to recreate the JSON census and TSV lookup. `generate_recipes.py` recreates the reviewed recipe data. `replay_diagnostics.py` actively executes the cases in fresh child workspaces. `crosswalk.py` relates observed exception tracebacks to explicit source sites. `run_reference_tests.py` checks the source census, hierarchy, diagnostic helper and bound replay receipts. `generate_manual.py` reproduces the cumulative and standalone Markdown and LaTeX files. PDF rendering and visual inspection remain distinct from textual-source reproducibility.

A single recipe can be replayed with the isolated worker launcher documented in the delivery README. The recipe JSON contains trusted executable fixture code; never run a modified recipe file received from an untrusted source merely because it has a familiar schema name. Hashes detect change, not authorship. The current outer manifest binds the delivered payload independently of the historical source and certificate-index manifests.

Appendix I is complete as a source-bound exception reference and finite diagnostic cookbook for this R2 snapshot. It is not an exhaustive dynamic test of all input sizes, all error branches, all optional dependencies or all operating systems. The 75 cases overlap with source tests and existing appendices; none is a new mathematical theorem or Lean proof. Passing a controlled negative-case expectation does not make the underlying denied operation successful.

Reference boundaries. The recorded diagnostic audit did not qualify native Windows/PowerShell, other Python versions, CUDA, strict MkDocs, fully dependency-isolated installation or final publication. The validation and hardening limitations in Appendices G and H remain relevant to that baseline. Appendix J addresses backend behavior, and Appendix O identifies the separate final-source execution records.

Appendix J. Backend and dependency matrix

Reference baseline: Komorebi Math 1.0.0b4, Repair R2, wheel build tag 2. This appendix records declared requirements, the actual integration contracts, and finite execution evidence. It is not a claim that every dependency version, platform, device or option combination has been tested.

Choose the operation before the dependency. The library has several integration points, and they use different selectors. Core linear algebra, automatic differentiation, packet execution and document compilation do not share one universal backend switch. J.3 is the decision point; J.2 tells you which extra declares the required Python distribution.

You want to do	Use the J.3 entry for	Then inspect
Work with numerical or symbolic matrices	NumPy or SymPy finite linear algebra	Vector shape, scalar conversion and zero-testing behavior
Differentiate a supported callable	JAX or PyTorch directional autodiff	Callable compatibility, derivative order, dtype and device
Execute a packet plan on CPU or GPU	NumPy and CuPy PacketIR execution	Setup, transfers and the returned execution certificate
Compile an exported document	External LaTeX engines	Executable discovery, required packages and the compilation result

For an unfamiliar environment, first reproduce a small operation from the relevant entry with the backend you intend to use. Record the selected backend and the result, not just whether an import succeeded. Use J.4 to understand the recorded environment, and Appendix O for the separate final-source qualification status. The historical environment tables here are evidence about those particular runs, rather than a prescription to copy every listed dependency.

J.1 Reading the qualification levels

Read five distinct levels: a distribution is **declared** in metadata; an import or executable is **discoverable**; its import and required capability may be **usable**; a particular operation can **execute successfully**; and a specified platform or release gate can be **qualified**. No arrow between these levels is automatic. An installed package can lack a usable device, and a favorable optional-gate aggregate can coexist with zero successful GPU executions.

This reference binds all 300 Python package source files, 191 explicit external import/discovery sites, three imports inside literal child-program strings, and seven retained dynamic expressions. The 19-method linear algebra protocol, ten dependency extras, all supplied environment constraints and both workflow definitions are indexed. Dynamic user-provided imports, extension names and transitive third-party implementations remain outside an exhaustive package-source census.

J.2 Declared installation and build contract

Field	Pinned source/wheel declaration
Distribution / namespace	`komorebi-math` / `komorebi_math`
Package / build	`1.0.0b4` / wheel build `2`
Python requirement	`>=3.11`
Wheel tag	`py3-none-any`
Required runtime dependency	`numpy>=1.26`

Field	Pinned source/wheel declaration
Build backend	`setuptools.build_meta`
Build-system requirements	`setuptools>=77.0.3`, `wheel`

The pure-Python wheel tag describes the Komorebi wheel, not the binary portability of NumPy, SciPy, JAX, PyTorch or CuPy. The NumPy dependency has no upper bound in project/wheel metadata. The separately supplied base constraint files add `<3`, but a constraint file only participates when the caller explicitly supplies it. Neither an absent upper bound nor a classifier certifies future Python or dependency versions.

Extra	Complete declared requirement list
`all`	`sympy>=1.12`, `scipy>=1.11`, `mpmath>=1.3`, `matplotlib>=3.8`, `PyYAML>=6.0`
`autodiff`	`jax>=0.4`, `torch>=2.1`
`dev`	`pytest>=8`, `build>=1.2`, `mypy>=1.10`, `ruff>=0.6`, `mkdocs>=1.6`
`exact`	`sympy>=1.12`
`jax`	`jax>=0.4`
`plot`	`matplotlib>=3.8`
`scientific`	`scipy>=1.11`, `mpmath>=1.3`
`test`	`pytest>=8`
`torch`	`torch>=2.1`
`yaml`	`PyYAML>=6.0`

The `all` extra is not universal. It combines SymPy, SciPy, mpmath, Matplotlib and PyYAML. It does not include JAX, PyTorch, CuPy, pytest or the development tools. `autodiff` combines JAX and PyTorch, but neither that extra nor the separate `jax` and `torch` extras promise CUDA support. No CuPy extra is declared. CUDA-specific distributions and runtime setup are separate environment choices. The import namespace `yaml` comes from the `PyYAML` distribution; the `cupy` namespace can be supplied by a CUDA-specific CuPy distribution.

The observed install used the shipped build-2 wheel, not an assumed public package-index release. Its digest is `c150c2f5b25551aebff7ccde8b2e57d03f1ffcbc569ce24cf7625cb2f607115e`. The exact `Requires-Dist` marker expansion is tested against every source extra and the base requirement. The recorded audit made no dependency downloads.

J.3 Selectors, protocols and integration boundaries

Interface	Built-in choices / meaning
`get_backend`	NumPy default; lazy SymPy adapter; caller registration is separate
`available_backends`	NumPy, SymPy, SciPy, mpmath and CuPy discovery flags
`backend_name(value)`	A type-module heuristic, not a general device/protocol registry
`packet_executor`	NumPy or CuPy finite packet execution
`autodiff_provider`	JAX or PyTorch derivative adapters
`cupy_runtime_status`	Module, device count, CUDA runtime and error record
`qualify_gpu`	Separate Torch/CuPy workers and required-backend flags
`resolve_latex_engine`	External compiler selection, independent of Python extras

Discoverable SciPy, mpmath or CuPy entries do not become core linear algebra backend names: the shipped `get_backend` rejects those names until an application explicitly registers a suitable implementation. JAX and PyTorch are separate derivative providers. Backend registration checks duplicate names but is not a full semantic protocol-

validation suite. A caller-supplied backend remains responsible for satisfying the abstract interface and its mathematical contracts.

The 19 abstract operations are: `as_matrix`, `as_vector`, `shape`, `zeros`, `eye`, `matmul`, `add`, `subtract`, `scale`, `transpose`, `adjoint`, `inverse`, `rank`, `norm`, `is_zero`, `column_stack`, `nullspace`, `kron`, `copy`. Both built-in implementations were exercised on small finite fixtures for each method. NumPy vectors are one-dimensional; SymPy vectors are column matrices. The same interface does not make their shapes, scalar types or zero-testing rules identical.

NumPy finite linear algebra

Selector or entry: `get_backend(None), get_backend('numpy')`. **Relevant distribution(s):** `numpy`.

Contract. The default core backend implements 19 abstract operations. Matrix conversion defaults to complex128. Vectors become one-dimensional arrays. Rank, nullspace, zero tests and norms are numerical and tolerance-dependent.

Failure and fallback behavior. Conversion rejects incompatible dimensions. Singular inverse errors can come from NumPy. A missing NumPy prevents root import; there is no whole-package standard-library-only mode.

Qualification boundary. Core exact=False is not a guarantee of error bounds. Small fixtures do not cover conditioning, overflow, all dtypes or large allocations. Recorded probes: `J01`, `J02`, `J03`.

Source binding: `backends/__init__.py`, `backends/numpy.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

SymPy finite linear algebra

Selector or entry: `get_backend('sympy')`. **Relevant distribution(s):** `sympy`.

Contract. Lazy exact-extra adapter. Vectors become column matrices. Rank, nullspace and is_zero ignore the numerical tolerance argument; norm requests a float from a symbolic expression.

Failure and fallback behavior. Discovery failure yields BackendUnavailableError. Unresolved symbolic norm conversion can raise TypeError. Float inputs remain SymPy Float rather than being silently converted to exact rationals.

Qualification boundary. The exact=True flag describes the adapter, not proof of exact provenance for every supplied scalar. Symbolic equality and numerical diagnostics are distinct. Recorded probes: `J04`, `J14`, `J17`, `J18`.

Source binding: `backends/__init__.py`, `backends/sympy.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

Exact finite Fraction and integer arithmetic

Selector or entry: `FormalSeries and finite coordinate/generating constructors`. **Relevant distribution(s):** `numpy`.

Contract. Many finite algebra paths use Python int and Fraction without requiring the SymPy backend. Root import still requires NumPy. The executed example multiplies two rational formal series exactly.

Failure and fallback behavior. Individual constructors enforce their own integral/rational/budget contracts. This entry is not a claim that every symbol in the exact research namespace is SymPy-free.

Qualification boundary. Large exact coefficient growth and the placement of local budgets are separate resource questions. Recorded probes: `J06`.

Source binding: `generating/series.py`, `generating/basis.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

Symbolic algebra, Smith and elimination paths

Selector or entry: `smith_decomposition and symbolic generating/deformation/elimination APIs`. **Relevant distribution(s):** `sympy`.

Contract. Operation-local lazy imports provide exact symbolic expressions, integer Smith transforms, lattices, polynomial elimination and closed forms. `smith_decomposition` directly imports `sympy.polys.matrices.normalforms.smith_normal_decomp`.

Failure and fallback behavior. Missing SymPy generally yields an exact-extra refusal. Missing sub-APIs can propagate import errors. The declared sympy>=1.12 metadata is not fresh proof that every operation works at that lower bound.

Qualification boundary. The recorded audit executed only the installed SymPy 1.14.0 capability. Do not reinterpret this as a sweep of historical SymPy versions. Recorded probes: `J15`, `J16`.

Source binding: `refinement/smith.py`, `refinement/lattices.py`, `generating/cyclotomic.py`, `generating/closed_forms.py`, `deformation/companions.py`, `nonlinear/elimination.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

SciPy matrix exponentials with operation-specific fallback

Selector or entry: `matrix_exponential(method='auto'\|'scipy'\|'taylor')`. **Relevant distribution(s):** `scipy`.

Contract. The dynamics auto route and cyclic fundamental_matrix can fall back to a NumPy scaling/Taylor path on ImportError. Explicit scipy mode requires SciPy. Numerical LinearRefinementDefect.exponential also requires SciPy; its SymPy route uses symbolic matrix.exp.

Failure and fallback behavior. Fallback is not universal. ImportError handling does not imply recovery from arbitrary binary-loader/runtime errors, failed convergence or invalid data.

Qualification boundary. Both SciPy and Taylor results are numerical. Symbolic defect validation still has its own assumptions and residual diagnostics. Recorded probes: `J07`, `J08`, `J09`, `J10`, `J11`, `J12`, `J13`.

Source binding: `dynamics/_linalg.py`, `analytic/sections.py`, `refinement/defects.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

mpmath Hurwitz-zeta leading model

Selector or entry: `reduced_zero_zeta(..., use_computed_zeros=False)`. **Relevant distribution(s):** `mpmath`.

Contract. The leading Hurwitz model imports mpmath lazily. Its certificate remains conditional because the entire correction is not supplied. The computed-zero branch follows a separate finite numerical route.

Failure and fallback behavior. The leading-model branch refuses an absent mpmath. Returned complex values do not turn the conditional model into a proved full formula.

Qualification boundary. Availability is not error control for all arguments or precision settings. The model result is converted to a Python complex. Recorded probes: `J21`, `J22`.

Source binding: `analytic/zeros.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

JAX directional autodiff

Selector or entry: `autodiff_provider('jax', ...) or JaxDerivativeProvider`. **Relevant distribution(s):** `jax`.

Contract. Lazy nested jax.jvp adapter. Discovery/import/capability probing runs in a child interpreter, caches two framework results, and exposes refresh=True diagnostics. Actual function evaluation returns NumPy host arrays through the provider validation path.

Failure and fallback behavior. An importable framework is not proof that a user function traces or a device operation succeeds. Dtype availability follows JAX configuration. Unsupported derivative order and incompatible dimensions are rejected.

Qualification boundary. The recorded audit executed CPU derivatives of a cubic through order three with x64 enabled. It did not qualify JAX CUDA or every compatible function, order, precision or version. Recorded probes: `J23`, `J24`, `J26`.

Source binding: `nonlinear/autodiff.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

PyTorch directional autodiff

Selector or entry: `autodiff_provider('torch', ...) or TorchDerivativeProvider`. **Relevant distribution(s):** `torch`.

Contract. Lazy nested torch.func.jvp adapter with explicit dtype/device options. The dtype defaults to float64 and device to None, leaving placement to the framework; the recorded audit explicitly selected cpu. Returned values detach and transfer to CPU NumPy arrays.

Failure and fallback behavior. Missing torch.func.jvp or an unusable import produces BackendUnavailableError. Unknown dtype produces ValidationError. Native operation errors may remain external errors.

Qualification boundary. Only the observed CPU build and cubic fixture are qualified here. A successful CPU JVP does not establish CUDA availability or zero-copy output. Recorded probes: `J23`, `J25`, `J26`.

Source binding: `nonlinear/autodiff.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

NumPy and CuPy PacketIR execution

Selector or entry: `packet_executor(ir, 'numpy'\|'cupy')`. **Relevant distribution(s):** `numpy`, `cupy`.

Contract. A selector separate from get_backend. CuPy materializes and uploads block matrices at setup. apply accepts return_host and input_on_device; synchronize is explicit. NumPy returns host data.

Failure and fallback behavior. Explicit CuPy selection refuses missing CuPy rather than silently choosing CPU. Discovery alone does not verify a CUDA driver or device.

Qualification boundary. Certificates report numerical execution. Transfer/setup cost, synchronization and timing must be accounted for separately. No GPU speed claim is made. Recorded probes: `J27`, `J29`, `J30`.

Source binding: `algorithms/gpu.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

CuPy persisted snapshot and polynomial execution

Selector or entry: `CuPySnapshotExecutor, CupyPacketJetExecutor and CupyPolynomialDerivativeProvider`. **Relevant distribution(s):** `cupy`.

Contract. Separate finite GPU executors for persisted packet-jet snapshots and polynomial plans. cupy_runtime_ status distinguishes installed module, runtime availability, device count, runtime version and error. Validation compares finite CPU/device values only when hardware is usable.

Failure and fallback behavior. Missing import, absent CUDA devices and external runtime errors are different states. The status helper catches ordinary exceptions but is not a shield against a native process abort.

Qualification boundary. All successful GPU execution remains unqualified on this host. General Python callbacks are not automatically made GPU-traceable by installing CuPy. Recorded probes: `J28`.

Source binding: `nonlinear/gpu.py`, `nonlinear/execution.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

CUDA release qualification

Selector or entry: `qualify_gpu(require_torch=True, require_cupy=True)`. **Relevant distribution(s):** `torch`, `cupy`.

Contract. Both backend workers execute in separate interpreters. Torch tests CUDA JVP and a matrix product; CuPy tests the Komorebi packet executor. Required flags control which failed backends invalidate the aggregate certificate.

Failure and fallback behavior. The required gate fails on this host. Making both backends optional yields a valid aggregate with zero backend passes, so inspect per-backend records and required flags.

Qualification boundary. An empty requirement set is not GPU evidence. This matrix retains raw negative qualification results. Recorded probes: `J30`, `J31`.

Source binding: `release/gpu.py`, `release/_gpu_worker.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

PyYAML presentation export

Selector or entry: `export_data(value, path ending in .yaml)`. **Relevant distribution(s):** `PyYAML`.

Contract. Lazy yaml.safe_dump of presentation-normalized values. The yaml extra supplies PyYAML; the import namespace is yaml.

Failure and fallback behavior. No PyYAML means BackendUnavailableError. Presentation YAML is not the portable round-trip object schema catalog of Appendix G.

Qualification boundary. Round-trip fixture testing is not untrusted-file security qualification. Recorded probes: `J19`, `J20`.

Source binding: `export/writers.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

Matplotlib optional plotting dependency

Selector or entry: `No package backend selector or direct package import in this census.` **Relevant distribution(s):** `matplotlib`.

Contract. The plot extra declares matplotlib>=3.8. The 300-file package scan has no direct Matplotlib import or literal dynamic import. A separate Agg rendering smoke test was executed for the dependency.

Failure and fallback behavior. A declared extra is not evidence that a public Komorebi plotting adapter exists.

Qualification boundary. The standalone offscreen render is not a package plotting-API acceptance test and does not test interactive displays. Recorded probes: `J32`.

This is a dependency-only entry. No package implementation file is invented to fill the source column.

External LaTeX engines

Selector or entry: `compile_latex(..., engine='auto'\|'pdflatex'\|'xelatex'\|'lualatex'\|'latexmk')`. **Relevant distribution(s):** external executables, not pip requirements.

Contract. Four PATH-discovered external commands, not pip extras. Auto tries lualatex, xelatex, pdflatex, then latexmk. Compilation returns a record whose validity and PDF path must be checked. Shell escape defaults off.

Failure and fallback behavior. No executable on PATH refuses engine selection. A discovered compiler can still fail because packages, fonts or source are invalid. Ordinary output overwrite guards are not universal compiler guards.

Qualification boundary. Each installed engine compiled one minimal document. Full manual builds separately require the retained TeX package set and Pandoc for source generation. Recorded probes: `J33`, `J34`, `J35`, `J36`, `J37`, `J38`.

Source binding: `export/latex.py`. Full file digests are retained in `Block42_Backend_Capability_Matrix.json`.

J.4 Observed versions and the platform matrix

The active replay used `3.13.5 (main, Jun 25 2025, 18:55:22) [GCC 14.2.0]`, platform `linux`. The package was installed separately and every source package file was compared with that installation. Most workers inherited host dependencies. Restricted profiles instead removed site initialization and exposed selected already-installed bytes. Neither method is a fresh dependency-isolated installation from a verified wheelhouse.

Distribution	Observed installed version
`PyYAML`	`6.0.3`
`build`	**Absent**
`cupy`	**Absent**
`cupy-cuda12x`	**Absent**
`jax`	`0.9.0.1`
`jaxlib`	`0.9.0.1`
`llvmlite`	`0.47.0`
`matplotlib`	`3.10.8`
`mkdocs`	**Absent**
`mpmath`	`1.3.0`

Distribution	Observed installed version
`mypy`	**Absent**
`numba`	`0.65.1`
`numpy`	`2.3.5`
`pytest`	`9.0.2`
`ruff`	**Absent**
`scipy`	`1.17.0`
`setuptools`	`82.0.1`
`sympy`	`1.14.0`
`torch`	`2.10.0+cpu`
`wheel`	`0.46.1`

A version entry is a metadata observation, not an execution qualification by itself. NumPy, SymPy, SciPy, mpmath and PyYAML have actual package-operation fixtures. JAX and PyTorch additionally ran actual CPU derivatives. Matplotlib rendered a standalone Agg figure, which is not a Komorebi plotting-API claim. NumPy/SciPy/AD results must not be equated with exact arithmetic merely because the arithmetic inputs were simple integers.

Target / evidence class	Current status
Linux, CPython 3.13.5	Source suite and this reference executed
NumPy 2.3.5 core	Nineteen operation fixtures and NumPy-only import-path profile pass
SymPy 1.14.0	Core interface, exact defect and Smith capability fixtures pass
SciPy 1.17.0 / mpmath 1.3.0	Listed finite operation fixtures pass
JAX 0.9.0.1 / PyTorch 2.10.0+cpu	Cubic CPU JVPs through order three pass
CUDA	Required gate fails; no backend execution qualified
Windows / PowerShell	No native execution in the recorded audit
CPython 3.11 / 3.12	Declared/CI-configured, not executed here
Other Python versions and operating systems	Not qualified by the recorded audit
Every declared dependency lower bound	Not tested as a version sweep
Strict MkDocs	Executable/module unavailable; not executed
Fresh dependency-isolated installation	Still pending

The Smith path directly requires `sympy.polys.matrices.normalforms.smith_normal_decomp`. The successful fixture proves this capability for the installed SymPy, not for every release admitted by `sympy>=1.12`. Similar callable checks in autodiff do not establish traceability or binary compatibility for every admitted framework build. This appendix therefore reports declared minima without labeling them tested minima.

J.5 Isolation, numeric policy and resource interpretation

The **base** profile launches the selected interpreter with `-I -S`, inserts the documentation worker path, and exposes only the pinned package and existing NumPy bytes through a temporary import directory. The **none** profile removes NumPy as well. Actual `find_spec` calls see the optional packages as absent: no mock backend replaces their functionality. The **base-empty-path** profile additionally clears PATH to exercise actual compiler-discovery refusal. These temporary profiles are local POSIX link-based tooling; native Windows link permissions and execution remain unqualified.

The **host** profile uses a separately installed pinned wheel with inherited dependencies. All package origins in the reference tests and worker receipts are checked against the installation rather than the source checkout. Crash-sensitive native operations execute in bounded child interpreters, so a child exit, signal or timeout becomes a recorded failure instead of silently disappearing. This is engineering containment, not a hostile-input sandbox or a memory quota.

The replay set `OMP_NUM_THREADS`, `OPENBLAS_NUM_THREADS` and `MKL_NUM_THREADS` to 1, selected `JAX_PLATFORMS=cpu`, and selected Agg for plotting. The JAX derivative fixture explicitly enabled 64-bit mode; the Torch fixture explicitly chose

CPU and float64. These settings document this experiment. They are not package-wide guarantees, thread-safety certification, performance benchmarks or universal numerical-accuracy defaults.

Input exactness must be explicit. NumPy defaults to complex128 in its core adapter. SymPy may preserve an input Float even though its backend flag says exact=True. SymPy norm evaluation can fail on an unresolved symbol, and a caller-supplied tolerance is ignored by its exact zero/rank/nullspace methods. AD providers report numerical results. GPU executors have setup/transfer/synchronization costs and may return host arrays. Do not infer speedups, device residence or proof status from a backend name alone.

J.6 Executed acceptance and refusal probes

The following 38 source-bound cases are deliberately finite. "Expectation passed" means the recorded operation, refusal or boundary observation matched its stated condition. In particular, J30 retains a failed required CUDA gate, and J31 demonstrates that requiring no backend can produce an aggregate pass with zero backend passes. Those two outcomes do not contradict one another.

J01 / Base import without optional distributions

Profile: `base`. **Evidence kind:** `operation`. **Expectation:** passed. NumPy-only import-path exposure works. Existing dependency bytes are reused. This is not a fresh dependency-isolated installation.

```
import importlib.util,sys
import komorebi_math
from komorebi_math.backends import available_backends
missing=['sympy','scipy','mpmath','yaml','matplotlib','jax','torch','cupy']
assert all(importlib.util.find_spec(n) is None for n in missing)
assert all(n not in sys.modules for n in missing)
assert available_backends()=={'numpy':True,'sympy':False,'scipy':False,'mpmath':False,'cupy':False}
observation={'base_import':True,'absent_optional_roots':missing,'discovery':available_backends()}
```

Observed output:

```
{
  "absent_optional_roots": [
    "sympy",
    "scipy",
    "mpmath",
    "yaml",
    "matplotlib",
    "jax",
    "torch",
    "cupy"
  ],
  "base_import": true,
  "discovery": {
    "cupy": false,
    "mpmath": false,
    "numpy": true,
    "scipy": false,
    "sympy": false
  }
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J01`. Receipt SHA-256: `a037ce982a1a74049bf98a0ff4d06667a6c169c69d3435da49c2f7219d247762`.

Source files: `backends/__init__.py`, `__init__.py`. Per-file hashes are retained in the matrix.

J02 / Root import actually requires NumPy

Profile: `none`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. No NumPy-free package import is established, even for exact submodules.

```
try:
 import komorebi_math
except ModuleNotFoundError as e:
 assert e.name=='numpy';observation={'refused':True,'missing':e.name}
else:raise AssertionError('Import unexpectedly worked without NumPy')
```

Observed output:

```
{
  "missing": "numpy",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J02`. Receipt SHA-256: `d5cf4b4d18041e4ecc2a1e8b5ea619dea508e83509424b06c56d0591b9f226f4`.

Source files: `__init__.py`, `backends/numpy.py`. Per-file hashes are retained in the matrix.

J03 / All 19 NumPy backend operations

Profile: `base`. **Evidence kind:** `operation`. **Expectation:** passed. Nineteen small numerical fixtures, not exhaustive linear algebra validation.

```
from backend_contracts import METHODS,exercise
observation={'methods':[exercise('numpy',m) for m in METHODS]}
```

Observed output:

```
{
  "all_finite_checks_passed": true,
  "backend": "numpy",
  "methods_exercised": 19
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J03`. Receipt SHA-256: `53b225a6a108f886d1fb135f32144e77999f3c7a5fa0d254b2f973394ed28934`.

Source files: `backends/base.py`, `backends/numpy.py`. Per-file hashes are retained in the matrix.

J04 / All 19 SymPy backend operations

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Nineteen finite SymPy fixtures at the observed version, not at every declared version.

```
from backend_contracts import METHODS,exercise
observation={'methods':[exercise('sympy',m) for m in METHODS]}
```

Observed output:

```
{
  "all_finite_checks_passed": true,
  "backend": "sympy",
  "methods_exercised": 19
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J04`. Receipt SHA-256: `a952c88a0b3cc9a35077eb1a04ded245641829aac85301823350b85db5dce28e`.

Source files: `backends/base.py`, `backends/sympy.py`. Per-file hashes are retained in the matrix.

J05 / Discovery is different from core selection

Profile: `host`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. Discovery entries for SciPy, mpmath and CuPy are not built-in core backend implementations.

```
from komorebi_math.backends import available_backends,get_backend
from komorebi_math.exceptions import BackendUnavailableError
seen=available_backends();refused=[]
for n in ('scipy','mpmath','cupy','jax','torch'):
 try:get_backend(n)
 except BackendUnavailableError:refused.append(n)
 else:raise AssertionError(n)
assert len(refused)==5 and get_backend().name=='numpy'
observation={'discovery':seen,'unsupported_core_names':refused}
```

Observed output:

```
{
  "discovery": {
    "cupy": false,
    "mpmath": true,
    "numpy": true,
    "scipy": true,
    "sympy": true
  },
  "unsupported_core_names": [
    "scipy",
    "mpmath",
    "cupy",
    "jax",
    "torch"
  ]
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J05`. Receipt SHA-256: `2337525a818810d39b5b13c69d8e5f78aa28cd742a5b294f4beeab40c266e5bb`.

Source files: `backends/__init__.py`. Per-file hashes are retained in the matrix.

J06 / Exact fractions without SymPy

Profile: `base`. **Evidence kind:** `operation`. **Expectation:** passed. Exact finite rational arithmetic does not universally require the SymPy adapter.

```
from fractions import Fraction
from komorebi_math.generating import FormalSeries,ordinary_basis
x=FormalSeries(ordinary_basis(),[Fraction(1,2),Fraction(1,3)])
y=x.multiply(x,degree=2)
assert y.coefficients==(Fraction(1,4),Fraction(1,3),Fraction(1,9))
observation={'coefficients':[str(v) for v in y.coefficients],'sympy_required':False}
```

Observed output:

```
{
  "coefficients": [
    "1/4",
    "1/3",
    "1/9"
  ],
  "sympy_required": false
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J06`. Receipt SHA-256: `ceedb5f3ad2e08c612048e4ce84309933fa1b5cbdef2eb07bb0e6c3abcfc4983`.

Source files: `generating/series.py`. Per-file hashes are retained in the matrix.

J07 / Auto exponential fallback with SciPy absent

Profile: `base`. **Evidence kind:** `operation`. **Expectation:** passed. The auto path has a numerical Taylor fallback on ImportError, not a blanket fallback for all SciPy failures.

```
import numpy as np
from komorebi_math.dynamics import matrix_exponential
m=np.array([[0.,1.],[0.,0.]])
a=matrix_exponential(m,method='auto');b=matrix_exponential(m,method='taylor')
assert np.allclose(a,[[1,1],[0,1]],atol=1e-12) and np.allclose(a,b,atol=1e-12)
observation={'auto':np.real(a).tolist(),'explicit_taylor_matches':True}
```

Observed output:

```
{
  "auto": [
    [
      1.0,
      1.0
    ],
    [
      0.0,
      1.0
    ]
  ],
  "explicit_taylor_matches": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J07`. Receipt SHA-256: `cf53e026c6a96296769f178967ba99348a8ef8b9bf0d18db0017436af71a1109`.

Source files: `dynamics/_linalg.py`. Per-file hashes are retained in the matrix.

J08 / Explicit SciPy mode refuses a missing SciPy

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. Explicit method selection preserves its dependency requirement.

```
from komorebi_math.dynamics import matrix_exponential
from komorebi_math.exceptions import BackendUnavailableError
try:matrix_exponential([[0.,1.],[0.,0.]],method='scipy')
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('Required SciPy not enforced')
```

Observed output:

```
{
  "message": "SciPy is required for method='scipy'",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J08`. Receipt SHA-256: `95cfb303c6d69789c05a5110508a3b97e7002f960a55fa2bc866e7e1c09b9501`.

Source files: `dynamics/_linalg.py`. Per-file hashes are retained in the matrix.

J09 / Cyclic fundamental matrix fallback

Profile: `base`. **Evidence kind:** `operation`. **Expectation:** passed. The cyclic section route can use the core numerical exponential fallback.

```
import numpy as np
from komorebi_math.analytic.sections import CyclicSectionFamily
x=CyclicSectionFamily(2)
a=x.fundamental_matrix(0.2)
b=np.array([[np.cos(0.2),-np.sin(0.2)],[np.sin(0.2),np.cos(0.2)]])
assert np.allclose(a,b,atol=1e-12) or np.allclose(a,b.T,atol=1e-12)
assert np.allclose(a@x.fundamental_matrix(-0.2),np.eye(2),atol=1e-12)
observation={'matrix':np.real(a).tolist(),'inverse_law':True}
```

Observed output:

```
{
  "inverse_law": true,
  "matrix": [
    [
      0.9800665778412416,
      -0.19866933079506124
    ],
    [
      0.19866933079506124,
      0.9800665778412416
    ]
  ]
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J09`. Receipt SHA-256: `94ce3a9a6383163bdbd0b7951a37cc0622eca8f6c3be40187931cf56d48d1d1d`.

Source files: `analytic/sections.py`, `dynamics/_linalg.py`. Per-file hashes are retained in the matrix.

J10 / Refinement exponential has no NumPy-only fallback

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. Fallback availability is operation-specific, not package-wide.

```
from komorebi_math.refinement.defects import LinearRefinementDefect
from komorebi_math.exceptions import BackendUnavailableError
x=LinearRefinementDefect([[1]],[[1]],[[0]])
try:x.exponential(0.1)
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('Expected scientific-extra refusal')
```

Observed output:

```
{
  "message": "matrix exponential defects require the 'scientific' SciPy extra",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J10`. Receipt SHA-256: `612af7f42c80aafcde5769e3a3a18d67192999712fb4f66082554fca8286f307`.

Source files: `refinement/defects.py`. Per-file hashes are retained in the matrix.

J11 / SciPy exponential matches the Taylor path

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Independent finite numerical path comparison at installed SciPy.

```
import numpy as np
from komorebi_math.dynamics import matrix_exponential
m=np.array([[0.,-1.],[1.,0.]])
a=matrix_exponential(m,method='scipy');b=matrix_exponential(m,method='taylor')
res=float(np.linalg.norm(a-b));assert res<1e-12
observation={'residual':res,'finite_matrix':m.tolist()}
```

Observed output:

```
{
  "finite_matrix": [
    [
      0.0,
      -1.0
    ],
    [
      1.0,
      0.0
    ]
  ],
  "residual": 1.9229626863835638e-16
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J11`. Receipt SHA-256: `cd422d86ee95d3a196914f72e63de9ca6646a5af4aa71a6620863eb4fdac94a4`.

Source files: `dynamics/_linalg.py`. Per-file hashes are retained in the matrix.

J12 / Scientific refinement exponential

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Numerical block-exponential identity for a scalar fixture, not exact arithmetic.

```
import numpy as np
from komorebi_math.refinement.defects import LinearRefinementDefect
r=LinearRefinementDefect([[1]],[[1]],[[0]]).exponential(0.1)
r.certificate.require();assert np.allclose(r.value,[[np.exp(.1)-1]],atol=1e-12)
observation={'valid':bool(r.certificate.valid),'exactness':str(r.certificate.exactness),'value'
    ↪ :np.real(r.value).tolist()}
```

Observed output:

```
{
  "exactness": "numerical",
  "valid": true,
  "value": [
    [
      0.10517091807564763
    ]
  ]
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J12`. Receipt SHA-256: `d4d894e1e12a4bc27bfaa3ba0c4d10b36f3e4b1c0c2f06fd635c5877ed10bf6e`.

Source files: `refinement/defects.py`. Per-file hashes are retained in the matrix.

J13 / SymPy refinement exponential

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. The symbolic route uses SymPy matrix.exp, not SciPy.

```
import sympy as sp
from komorebi_math.refinement.defects import LinearRefinementDefect
r=LinearRefinementDefect([[1]],[[1]],[[0]],backend='sympy').exponential(sp.Rational(1,10))
r.certificate.require();assert sp.simplify(r.value[0,0]-(sp.exp(sp.Rational(1,10))-1))==0
observation={'valid':bool(r.certificate.valid),'value':str(r.value),'exactness':str(r.certificate.exactness)}
```

Observed output:

```
{
  "exactness": "exact",
  "valid": true,
  "value": "Matrix([[-1 + exp(1/10)]])"
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J13`. Receipt SHA-256: `223dcfa5e58bd27b86664a7dfdf34595f94568284eaa84684ac3c3d6aeccb5ac`.

Source files: `refinement/defects.py`. Per-file hashes are retained in the matrix.

J14 / Missing SymPy adapter refusal

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. The exact extra is required for the SymPy core adapter.

```
from komorebi_math.backends import get_backend
from komorebi_math.exceptions import BackendUnavailableError
try:get_backend('sympy')
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('SymPy should be absent')
```

Observed output:

```
{
  "message": "the SymPy backend requires the 'exact' optional dependency",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J14`. Receipt SHA-256: `edec6322efccd0f7aa9ad168f936f2f5e028b69001485f2a0128f01bad5f0a60`.

Source files: `backends/__init__.py`. Per-file hashes are retained in the matrix.

J15 / Smith normal decomposition capability

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. The installed release supplies the required Smith API. The declared lower bound is not thereby qualified.

```
from komorebi_math.refinement.smith import smith_decomposition
r=smith_decomposition([[2,4],[0,6]]);r.certificate().require()
assert r.left*r.matrix*r.right==r.diagonal
observation={'invariant_factors':r.invariant_factors,'valid':bool(r.certificate().valid),'required_symbol':
    ↪ 'sympy.polys.matrices.normalforms.smith_normal_decomp'}
```

Observed output:

```
{
  "invariant_factors": [
    2,
    6
  ],
  "required_symbol": "sympy.polys.matrices.normalforms.smith_normal_decomp",
  "valid": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J15`. Receipt SHA-256: `31953284d6d54315b2c829fe8be1eba98e7468ff5e750d30a440866e8538a82b`.

Source files: `refinement/smith.py`. Per-file hashes are retained in the matrix.

J16 / Missing SymPy Smith refusal

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. No silent numeric substitution for an exact Smith operation.

```
from komorebi_math.refinement.smith import smith_decomposition
from komorebi_math.exceptions import BackendUnavailableError
try:smith_decomposition([[2]])
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('SymPy should be absent')
```

Observed output:

```
{
  "message": "Smith coordinate operations require the 'exact' SymPy extra",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J16`. Receipt SHA-256: `50756c355a46f0b9e91214007ac1024a02d4ec05835ddb2f49a74fdaa4e0fa3b`.

Source files: `refinement/smith.py`. Per-file hashes are retained in the matrix.

J17 / SymPy exact flag does not rationalize float inputs

Profile: `host`. **Evidence kind:** `boundary-observation`. **Expectation:** passed. Choose exact input types explicitly. The backend flag is not input-provenance validation.

```
import sympy as sp
from komorebi_math.backends import get_backend
b=get_backend('sympy');m=b.as_matrix([[0.1]])
assert b.exact is True and isinstance(m[0,0],sp.Float)
observation={'backend_exact_flag':b.exact,'stored_scalar_type':type(m[0,0]).__name__,'value':str(m[0,0])}
```

Observed output:

```
{
  "backend_exact_flag": true,
  "stored_scalar_type": "Float",
  "value": "0.100000000000000"
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J17`. Receipt SHA-256: `bb450a5a8682335d5062d8341bf875982987fe20d8ec33c80e033695c31e22ca`.

Source files: `backends/sympy.py`. Per-file hashes are retained in the matrix.

J18 / SymPy norm can reject unresolved symbols

Profile: `host`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. A symbolic matrix type does not guarantee every numerical diagnostic can evaluate it.

```
import sympy as sp
from komorebi_math.backends import get_backend
b=get_backend('sympy')
try:b.norm(b.as_matrix([[sp.Symbol('x')]]))
except TypeError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('Unresolved symbol unexpectedly produced a floating norm')
```

Observed output:

```
{
  "message": "Cannot convert expression to float",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J18`. Receipt SHA-256: `3bd74a783d1dc6e6eabdc2ee7a10bebdb69740a565f9593c9ab4ce4380f9f613`.

Source files: `backends/sympy.py`. Per-file hashes are retained in the matrix.

J19 / YAML export and parse-back

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. PyYAML supplies presentation export; this is not the portable-object codec.

```
import yaml
from komorebi_math.export import export_data
p=work/'record.yaml';export_data({'a':[1,2],'ok':True},p)
a=yaml.safe_load(p.read_text());assert a=={'a':[1,2],'ok':True}
observation={'parsed':a,'output':p.name}
```

Observed output:

```
{
  "output": "record.yaml",
  "parsed": {
    "a": [
      1,
      2
    ],
    "ok": true
  }
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J19`. Receipt SHA-256: `c55dd5eec4e2347b202b7a9bc6b8070d38b1b75445d3c7c6c3112a7d7c3a4f0c`.

Source files: `export/writers.py`. Per-file hashes are retained in the matrix.

J20 / YAML export absent-dependency refusal

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. YAML is optional and no handwritten YAML fallback is substituted.

```
from komorebi_math.export import export_data
from komorebi_math.exceptions import BackendUnavailableError
try:export_data({'a':1},work/'record.yaml')
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('PyYAML should be absent')
```

Observed output:

```
{
  "message": "YAML export requires PyYAML, install komorebi-math[yaml]",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J20`. Receipt SHA-256: `19fd94c90eea59ba21a830eb8ca62cabae4ea97f7acd28bd12dadfb899fb3bf6`.

Source files: `export/writers.py`. Per-file hashes are retained in the matrix.

J21 / mpmath leading zero-zeta model

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. The leading Hurwitz model remains conditional. mpmath availability does not supply the omitted correction.

```
import numpy as np
from komorebi_math.analytic.zeros import reduced_zero_zeta
r=reduced_zero_zeta(2,1,use_computed_zeros=False)
assert abs(r.value-.5)<1e-12
observation={'value_real':r.value.real,'value_imag':r.value.imag,'exactness':str(r.certificate.exactness),
    ↪ 'unchecked':r.certificate.assumptions_unchecked}
```

Observed output:

```
{
  "exactness": "conditional",
  "unchecked": [
    "entire correction term"
  ],
  "value_imag": 0.0,
  "value_real": 0.5
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J21`. Receipt SHA-256: `68d3c784d9c7addf028b2555090f8c0f4956793298be9111aa85cb4b33f08004`.

Source files: `analytic/zeros.py`. Per-file hashes are retained in the matrix.

J22 / Missing mpmath leading-model refusal

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. The scientific extra is required for this branch.

```
from komorebi_math.analytic.zeros import reduced_zero_zeta
from komorebi_math.exceptions import BackendUnavailableError
try:reduced_zero_zeta(2,1,use_computed_zeros=False)
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('mpmath should be absent')
```

Observed output:

```
{
  "message": "the Hurwitz zeta model requires the scientific extra",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J22`. Receipt SHA-256: `f38f5e04a049654839f52d6a80c5203bebb74fc01573bc8f0b30b8c860319895`.

Source files: `analytic/zeros.py`. Per-file hashes are retained in the matrix.

J23 / Native AD discovery and capability report

Profile: `host`. **Evidence kind:** `capability-observation`. **Expectation:** passed. A child import plus callable capability check is weaker than actually evaluating a derivative.

```
from komorebi_math.nonlinear.autodiff import ad_framework_diagnostics
observation=ad_framework_diagnostics(refresh=True)
assert set(observation)=={'jax','torch'}
for r in observation.values():assert isinstance(r['available'],bool) and isinstance(r['discovered'],bool)
```

Observed output:

```
{
  "jax": {
    "available": true,
    "discovered": true,
    "returncode": 0,
    "version": "0.9.0.1"
  },
  "torch": {
    "available": true,
    "discovered": true,
    "returncode": 0,
    "version": "2.10.0+cpu"
  }
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J23`. Receipt SHA-256: `c01f21d40b0abe854ecea698a24d599eab4e4f12339ef73148f2b654b03933f7`.

Source files: `nonlinear/autodiff.py`. Per-file hashes are retained in the matrix.

J24 / JAX CPU derivatives through order three

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Actual CPU derivative execution. No CUDA, transfer-cost or performance qualification is implied.

```
import numpy as np
import jax,jax.numpy as jnp
from komorebi_math.nonlinear.autodiff import JaxDerivativeProvider
jax.config.update('jax_enable_x64',True)
p=JaxDerivativeProvider(lambda x:jnp.stack((x[0]**3+x[0]*x[1],x[1]**3)),2,2,max_order=3,dtype='float64')
point=[2.,3.];directions=([1.,0.],)*3
assert np.allclose(p.value(point),[14.,27.],atol=1e-12)
actual=[p.derivative(n,point,directions[:n]).tolist() for n in (1,2,3)]
assert np.allclose(actual,[[15,0],[12,0],[6,0]],atol=1e-12)
observation={'version':jax.__version__,'device_platform':jax.default_backend(),'jax_enable_x64':bool
    ↪ (jax.config.jax_enable_x64),'derivatives':actual,'certificate_exactness':str(p.exactness)}
```

Observed output:

```
{

Source files: `nonlinear/autodiff.py`. Per-file hashes are retained in the matrix.

J27 / NumPy packet execution

Profile: `base`. **Evidence kind:** `operation`. **Expectation:** passed. The packet-executor selector is separate from the core linear algebra selector.

```
import numpy as np
from komorebi_math.algorithms import PacketIR,PacketLayout,packet_executor
ir=PacketIR.square(PacketLayout((2,2)),{(0,0):np.eye(2),(1,1):2*np.eye(2)})
r=packet_executor(ir,'numpy').apply(np.arange(4.))
assert np.allclose(r.value,[0,1,4,6]) and r.backend=='numpy' and r.returned_to_host
observation={'value':r.value.tolist(),'backend':r.backend,'returned_to_host':r.returned_to_host}
```

Observed output:

```
{
  "backend": "numpy",
  "returned_to_host": true,
  "value": [
    0.0,
    1.0,
    4.0,
    6.0
  ]
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J27`. Receipt SHA-256: `df77c0dd0ba642c5cddf352c0076529f95c82b592af10b743031f803cf1a3ac1`.

Source files: `algorithms/gpu.py`. Per-file hashes are retained in the matrix.

J28 / CuPy runtime report on this host

Profile: `host`. **Evidence kind:** `hardware-unavailable`. **Expectation:** passed. CuPy is genuinely absent on the audited host. This is a negative hardware observation.

```
from dataclasses import asdict
from komorebi_math.nonlinear.gpu import cupy_runtime_status
observation=asdict(cupy_runtime_status())
assert observation['installed'] is False and observation['runtime_available'] is False
```

Observed output:

```
{
  "device_count": 0,
  "error": "CuPy is not installed",
  "installed": false,
  "runtime_available": false,
```

```
  "runtime_version": null
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J28`. Receipt SHA-256: `ef13a71567b4cdee5639f1164d4a32c0528eb1f3afaf42e43ac0cbcfa3d46dcb`.

Source files: `nonlinear/gpu.py`. Per-file hashes are retained in the matrix.

J29 / Missing CuPy packet-executor refusal

Profile: `base`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. There is no silent CPU fallback when CuPy is explicitly selected.

```
import numpy as np
from komorebi_math.algorithms import PacketIR,PacketLayout,packet_executor
from komorebi_math.exceptions import BackendUnavailableError
ir=PacketIR.square(PacketLayout((1,)),{(0,0):np.eye(1)})
try:packet_executor(ir,'cupy')
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('CuPy should be absent')
```

Observed output:

}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J30`. Receipt SHA-256: `0b0feb81d6533f901aecfb02026caa8ba78af9e175d9980fc067e37fa4e19f75`.

Source files: `release/gpu.py`, `release/_gpu_worker.py`. Per-file hashes are retained in the matrix.

J31 / Optional GPU flags do not prove GPU execution

Profile: `host`. **Evidence kind:** `boundary-observation`. **Expectation:** passed. An empty required-backend set can pass with zero successful GPU executions.

```
from komorebi_math.release.gpu import qualify_gpu
r=qualify_gpu(require_torch=False,require_cupy=False,timeout=60)
assert r.certificate.valid and all(not b.passed for b in r.backends)
observation={'qualification_passed':bool(r.certificate.valid),'required_backends':[],'actual_backend_passes':0,
    ↪ 'unchecked':r.certificate.assumptions_unchecked}
```

Observed output:

```
{
  "actual_backend_passes": 0,
  "qualification_passed": true,
  "required_backends": [],
  "unchecked": [
    "torch was optional for this invocation",
    "cupy was optional for this invocation"
  ]
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J31`. Receipt SHA-256: `8c10abae2a0a1b0099ae9ec93a84ecc14fc5ac7ee13a8667db9097251ffc1400`.

Source files: `release/gpu.py`. Per-file hashes are retained in the matrix.

J32 / Declared plotting extra can render offscreen

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. A standalone dependency smoke test, not evidence of a plotting backend API in Komorebi Math.

```
import matplotlib
matplotlib.use('Agg')
import matplotlib.pyplot as plt
fig,ax=plt.subplots();ax.plot([0,1,2],[0,1,4]);ax.set(xlabel='x',ylabel='x
    ↪ squared');p=work/'plot.png';fig.savefig(p);plt.close(fig)
assert p.read_bytes().startswith(b'\x89PNG\r\n\x1a\n')
observation={'version':matplotlib.__version__,'backend':matplotlib.get_backend(),'output_bytes':p.stat().st_size,
    ↪ 'package_plotting_api_claim':False}
```

Observed output:

```
{
  "backend": "Agg",
  "output_bytes": 21139,
  "package_plotting_api_claim": false,
  "version": "3.10.8"
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J32`. Receipt SHA-256: `7bdb0f90525268ef01b104eb4089f13ea0dee6ba6ab3656141fa3fc348af0fe9`.

J33 / Native pdflatex PDF compilation

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Actual compiler execution on a minimal TeX fixture. It does not qualify every document or font.

```
from komorebi_math.export.latex import compile_latex,LatexCompileOptions
text=r'\documentclass{article}\begin{document}Komorebi P. $1+1=2$.\end{document}'
r=compile_latex(text,work/'tex',options=LatexCompileOptions(engine='pdflatex',passes=1,timeout=45))
p=r.require();assert p.read_bytes().startswith(b'%PDF-')
observation={'engine':str(r.engine),'valid':bool(r.valid),'pdf_bytes':p.stat().st_size,'return_codes'
    ↪ :r.return_codes,'shell_escape':False}
```

Observed output:

```
{
  "engine": "pdflatex",
  "pdf_bytes": 13505,
  "return_codes": [
    0
  ],
  "shell_escape": false,
  "valid": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J33`. Receipt SHA-256: `f4c44f902ba5fe01e088377aaaf8f3099476a5a45e95c18229584b3351198248`.

Source files: `export/latex.py`. Per-file hashes are retained in the matrix.

J34 / Native xelatex PDF compilation

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Actual compiler execution on a minimal TeX fixture. It does not qualify every document or font.

```
from komorebi_math.export.latex import compile_latex,LatexCompileOptions
text=r'\documentclass{article}\begin{document}Komorebi P. $1+1=2$.\end{document}'
r=compile_latex(text,work/'tex',options=LatexCompileOptions(engine='xelatex',passes=1,timeout=45))
p=r.require();assert p.read_bytes().startswith(b'%PDF-')
observation={'engine':str(r.engine),'valid':bool(r.valid),'pdf_bytes':p.stat().st_size,'return_codes'
    ↪ :r.return_codes,'shell_escape':False}
```

Observed output:

```
{
  "engine": "xelatex",
  "pdf_bytes": 4306,
  "return_codes": [
    0
  ],
  "shell_escape": false,
  "valid": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J34`. Receipt SHA-256: `ef268524c4f01d3e6caad26d6eee81da991c151146e2e641d9d00402a82c13ed`.

Source files: `export/latex.py`. Per-file hashes are retained in the matrix.

J35 / Native lualatex PDF compilation

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Actual compiler execution on a minimal TeX fixture. It does not qualify every document or font.

```
from komorebi_math.export.latex import compile_latex,LatexCompileOptions
text=r'\documentclass{article}\begin{document}Komorebi P. $1+1=2$.\end{document}'
r=compile_latex(text,work/'tex',options=LatexCompileOptions(engine='lualatex',passes=1,timeout=45))
p=r.require();assert p.read_bytes().startswith(b'%PDF-')
observation={'engine':str(r.engine),'valid':bool(r.valid),'pdf_bytes':p.stat().st_size,'return_codes'
    ↪ :r.return_codes,'shell_escape':False}
```

Observed output:

```
{
  "engine": "lualatex",
  "pdf_bytes": 11570,
  "return_codes": [
    0
  ],
  "shell_escape": false,
  "valid": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J35`. Receipt SHA-256: `037c0cdf2fbd42b51aab3b4b22e87edd2bfce8a076d5a08cd6dd0aa3ab94d124`.

Source files: `export/latex.py`. Per-file hashes are retained in the matrix.

J36 / Native latexmk PDF compilation

Profile: `host`. **Evidence kind:** `operation`. **Expectation:** passed. Actual compiler execution on a minimal TeX fixture. It does not qualify every document or font.

```
from komorebi_math.export.latex import compile_latex,LatexCompileOptions
text=r'\documentclass{article}\begin{document}Komorebi P. $1+1=2$.\end{document}'
r=compile_latex(text,work/'tex',options=LatexCompileOptions(engine='latexmk',passes=1,timeout=45))
p=r.require();assert p.read_bytes().startswith(b'%PDF-')
observation={'engine':str(r.engine),'valid':bool(r.valid),'pdf_bytes':p.stat().st_size,'return_codes'
    ↪ :r.return_codes,'shell_escape':False}
```

Observed output:

```
{
  "engine": "latexmk",
  "pdf_bytes": 13505,
  "return_codes": [
    0
  ],
  "shell_escape": false,
  "valid": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J36`. Receipt SHA-256: `f9453561232428a361adbd172c8de535b04d66a5c7b18e81292e9e84bb0eaf8b`.

Source files: `export/latex.py`. Per-file hashes are retained in the matrix.

J37 / No compiler on PATH

Profile: `base-empty-path`. **Evidence kind:** `expected-refusal`. **Expectation:** passed. An empty child PATH tests real executable discovery refusal, not mocked shutil.

```
from komorebi_math.export.latex import resolve_latex_engine,available_latex_engines
from komorebi_math.exceptions import BackendUnavailableError
assert not any(available_latex_engines().values())
try:resolve_latex_engine('auto')
except BackendUnavailableError as e:observation={'refused':True,'message':str(e)}
else:raise AssertionError('No compiler should be discoverable')
```

Observed output:

```
{
  "message": "no supported LaTeX engine was found on PATH",
  "refused": true
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J37`. Receipt SHA-256: `07f95b95dafb64ffa19d55d058e877899b568bd7f0b9538bee4ce10504a27e2b`.

Source files: `export/latex.py`. Per-file hashes are retained in the matrix.

J38 / Latex engine discovery and default ordering

Profile: `host`. **Evidence kind:** `capability-observation`. **Expectation:** passed. Executable discovery is not proof a particular document will build.

```
from komorebi_math.export.latex import resolve_latex_engine,available_latex_engines
observation={'discovered':available_latex_engines(),'selected_auto':str(resolve_latex_engine('auto'))}
assert observation['discovered'][observation['selected_auto']]
```

Observed output:

```
{
  "discovered": {
    "latexmk": true,
    "lualatex": true,
    "pdflatex": true,
    "xelatex": true
  },
  "selected_auto": "lualatex"
}
```

The recipe runner supplies `work` as a fresh directory; `backend_contracts.py` is the supplied finite-interface helper. Complete stdout, stderr, generated files, module origins and the receipt are under `backend_replay/J38`. Receipt SHA-256: `bd835c211527fe7c631785db02d2183aa0997be665221144808d7854b00c1720`.

Source files: `export/latex.py`. Per-file hashes are retained in the matrix.

J.7 Complete electronic dependency-site census

External import root	Explicit package import/discovery sites
`cupy`	11
`jax`	2
`mpmath`	2
`numpy`	135
`scipy`	4
`sympy`	33
`torch`	3
`yaml`	1

The totals count source sites, including verification modules and repeated uses. They are not the number of required installations or mathematical algorithms. `Block42_Backend_Dependency_Index.json` retains source lines, columns, owners, exact statements, ancestor conditions and source hashes for every site; `Block42_Dependency_Source_Lookup.tsv` supplies all 191 lookup rows. The 135 NumPy sites remain in that full electronic inventory rather than being hidden by the shorter optional-path table below.

Optional root	Package source and line	Site kind
`cupy`	`algorithms/gpu.py:18`	`discovery`
`cupy`	`algorithms/gpu.py:65`	`import`
`sympy`	`analytic/appell.py:93`	`import`
`sympy`	`analytic/appell.py:136`	`import`
`sympy`	`analytic/reciprocal.py:83`	`import`
`scipy`	`analytic/sections.py:266`	`from`
`mpmath`	`analytic/zeros.py:217`	`import`
`sympy`	`arithmetic/recurrence.py:286`	`import`
`sympy`	`backends/__init__.py:26`	`discovery`

sympy	verify/deformation.py:60	discovery
sympy	verify/refinement.py:73	discovery
sympy	verify/refinement.py:75	import

Literal JAX/Torch child programs contain three additional imports. Seven dynamic expressions are retained without pretending their runtime strings form a closed external dependency set. Examples include extension/module names selected at runtime and compiler choices held in variables. Matplotlib, Numba and llvmlite have no direct import in the scanned package statements; this does not mean external dependencies never import them transitively.

J.8 Constraints, historical environments and CI declarations

The supplied Python 3.11, 3.12 and 3.13 base constraints all state `numpy>=1.26,<3`. The development constraints add bounded pytest/build and development tools. The Windows CUDA files are retained recorded environment profiles, not the active Linux environment and not independently rerun validations. Their filenames containing “validated” do not qualify R2 on this host.

  - python=3.13
  - pip
  - pip:
      - numpy==2.5.2
      - jax==0.11.1
      - cupy-cuda12x==14.1.1
      - numba==0.67.0
      - llvmlite>=0.49,<0.50
      - pytest==9.1.1
      # Install PyTorch separately from the official cu126 index:
      # python -m pip install torch==2.12.1 torchvision==0.27.1 --index-url https://download.pytorch.org/whl/cu126
```

The CUDA constraint file containing Torch names pins `torch==2.12.1+cu126` and `torchvision==0.27.1+cu126`; the "validated" companion omits those lines and points to separate installation instructions. The environment YAML similarly leaves Torch installation to a separate commented command. These are historical source contents. The recorded audit neither fetched those releases nor established that the listed versions form a resolvable environment now. Numba/llvmlite pins are environment context, not declared Komorebi package requirements.

The CPU workflow declares a Linux/Windows by Python-3.11/3.12/3.13 job matrix, plus Linux documentation and distribution jobs. The tagged workflow checks the repaired release identity. Their definitions request package tests, API checks, distribution rebuilding, strict MkDocs and clean artifact checks, but the recorded audit executed no hosted workflow. The complete files and hashes remain in the JSON index. A configured job is not a passing job receipt.

J.9 Reproduction and acceptance checklist

From a fresh working copy, select an interpreter where the unchanged build-2 wheel is installed and the needed test dependencies are available. The runtime probe tool checks all 366 package-file hashes and refuses a source-checkout import. It makes no dependency installations or network requests. Run data generation and tests in a working copy because regenerated files or receipts invalidate the outer archive hashes.

```
python tools/block42/inventory.py
python tools/block42/run_probes.py --output manual/verification/block42-appendix-j/backend_replay
python tools/block42/generate_matrix.py
python tools/block42/run_reference_tests.py
python tools/block42/run_source_tests.py
python tools/block42/generate_manual.py
```

```
python tools/block42/build_pdfs.py
python VERIFY_BLOCK42_PACKAGE.py
```

The reference tests require pytest and packaging in addition to the selected numerical environment. PDF regeneration uses Pandoc, pdflatex and the inherited TeX packages; PDF inspection uses PyMuPDF and Pillow. These are documentation tools, not additions to the mathematical library runtime requirements. The probe suite is pinned to this audited CPU host profile. A different hardware configuration needs reviewed expectations rather than relabeling an unexpected GPU success or failure.

Executed check	Result
Complete unchanged source tests	1,203 passed
Reference/source/metadata/interface tests	618 passed
Actual probe expectations	38/38 satisfied
Finite native LaTeX engine fixtures	4/4 produced PDFs
Built-in linear algebra methods exercised	19 per backend
Required GPU qualification	Failed, retained as negative
Library files preserved against R2	901/901 identical
Package files versus installation	366/366 identical

The source suite, method fixtures, source-index tests and saved-receipt checks overlap. They are not additive counts of independent mathematical theorems. The 618 reference tests include per-file and per-site checks, not that many independent backend workloads. Test receipts must be read with their current input bindings, not only with an old passing count.

J.10 Completion boundary and next appendix

Reference boundaries. This version-bound backend and dependency reference records the listed finite Linux observations. That audit did not qualify native Windows/PowerShell, other Python versions, dependency lower bounds, CUDA, strict MkDocs, fresh dependency-isolated installation or final publication. Portable-decoder and certificate-validation limitations remain separate. No new Lean proof audit formed part of those observations; Appendix O identifies the final-source qualification records.

Resource models and guards are described in Appendix K. Changing a documentation file alone does not change the installed mathematical package or its qualification.

Appendix K. Complexity, memory, and resource-budget tables

Reference baseline: Komorebi Math 1.0.0b4, Repair R2, wheel build tag 2. This appendix gives source-derived operation and storage models, the complete explicitly defined budget fields, a lexical parameter and guard census, and bounded execution evidence. It is not a proof that every operation has a budget, that every cap runs before allocation, or that the process is protected against arbitrary untrusted input.

Estimate the request before increasing a limit. Start with the operation profile in K.4, check when its guard runs in K.3, and use the worksheet in K.10 before allocating a larger problem. K.5 translates several common shapes into payload sizes; K.9 explains why a long-lived process can retain more memory than one result suggests.

For each planned run, write down four quantities: the number of output entries, their scalar representation, the additional work needed to produce them, and the point where the selected limit is checked. This separates a manageable output from an expensive construction. A small sparse result, for example, does not by itself show that discovering its support was cheap.

A small reading example. For a dense packet tensor, use the source dimension, target dimension and derivative order in the shape formula given below. Compare the resulting cell count with the element cap first. Next convert cells to bytes using the actual dtype, and allow separately for inputs and temporaries. For exact objects, include the represented integers or fractions as well as array slots. The resource record should retain these assumptions so that a later change of dtype or order does not reuse an obsolete estimate.

K.1 Units, parameters, and what a bound establishes

Use four distinct ledgers. **Cardinality** counts entries, states, addresses, paths or callback invocations. **Arithmetic work** counts scalar operations under a stated model. **Bit work** additionally accounts for the sizes of exact numerators, denominators and intermediate values. **Observed resources** are time and allocations measured in one execution. A bound in one ledger does not automatically bound the others.

Symbol	Meaning in this appendix
`n, m`	Ambient source and target dimension
`p, q`	Number of source and target packets
`r`	Derivative order or explicitly named lattice rank
`N`	Requested truncation degree, hence `N+1` coefficients
`k`	Recurrence order or explicitly named inner matrix dimension
`V, E`	Unique expression nodes and traversed child edges
`B`	Actual JSON bytes, or explicitly named quantized error allowance
`L, S`	Visited-state count or reached-automaton states, as stated locally
`w`	Fixed-width element size in bytes

A dense fixed-width array with shape `(d0,...,dt)` has logical data-buffer size `w*product(di)`. For object arrays, this formula counts pointer slots, not the referenced Python objects. Views can share an underlying allocation. Python container headers, tuple pointers, integer payload, allocation overhead, temporaries, retained caches, native libraries and device memory must be considered separately. A sum of object sizes can double-count shared references and is still not peak process resident memory.

Every big-O statement below is a reviewed model of the specified implementation, with its source location and checksum in the ledger. It is not an independently verified asymptotic theorem. Classical dense matrix multiplica-

tion is modeled by cubic scalar work; no claim is made that every backend uses exactly that algorithm or the same workspace. For exact arithmetic, replace constant scalar cost by the appropriate cost at the actual intermediate bit sizes. User callbacks and basis normalization functions have separate cost contracts.

K.2 All three explicit budget objects

The package declares three named budget dataclasses with **20 fields**. All fields require positive integer values and reject booleans in construction. The guards on the operations they govern differ. The objects are local arguments or stored records, not process-wide controllers. Defaults below are pinned source values, not recommended maximum workloads.

GeneratingBudget

Field	Exact default
`maximum_degree`	100,000
`maximum_coefficient_bits`	4,000,000
`maximum_matrix_dimension`	4,096
`maximum_reachable_states`	100,000
`maximum_local_combinations`	1,000,000
`maximum_modulus`	2,000,000
`maximum_serialized_bytes`	67,108,864
`maximum_recursion_depth`	1,000

`require_degree`, `require_terms`, `require_serialized_bytes` and `require_coefficient_bits` permit zero requests; dimensions, states, local combinations and modulus require positive requests. Equality with the cap is accepted, one above is refused with `ResourceLimitError`. `require_terms` and `require_local_combinations` use the same field but differ on zero. `max_modulus_table` is a compatibility property for `maximum_modulus`.

Enforcement is not automatic. The eight standalone guard methods are callable contracts. This snapshot contains no explicit package call to `require_serialized_bytes`, and `maximum_recursion_depth` has no associated guard method. These fields are preserved by serialization, but the generic portable codec does not adopt them as its own policy. With `maximum_serialized_bytes=1`, a finite-series object still serializes to a larger envelope. Setting `maximum_recursion_depth=1` does not replace the codec argument `max_depth`. The source census is lexical, not a proof that an arbitrary caller could never invoke a guard dynamically.

`FiniteNormalizedSeries` checks degree and recognized coefficient bit sizes, but first consumes and coerces the entire supplied iterable. It checks output coefficient bits when constructing results, not after every intermediate addition or multiplication. The helper recognizes `int` and `Fraction`; other domain representations can have a helper bit count of zero. The unbudgeted `FormalSeries` is a separate class. A permitted degree of 100,000 can request **5,000,150,001 convolution terms** in the triangular implementation; the default is not a promise that such a run is practical.

Source: `generating/budget.py`. Complete field expressions and source SHA-256 values are in `Block43_Resource_Complexity_Index.json`.

CoordinateBudget

Field	Exact default
`maximum_matrix_dimension`	512
`maximum_polynomial_degree`	512
`maximum_horizon`	4,096
`maximum_exact_entries`	1,000,000

`require_matrix(rows, columns, operation=...)` applies both per-dimension and entry-product limits. Degree and horizon have separate methods. In the dense Boolean-lattice transform, the matrix guard precedes the comprehension. At default dimension 512, rank 9 reaches the dimension boundary and rank 10 is refused. This statement is arithmetic and source inspection; no default-maximum rank-9 benchmark was run.

The low-level matrix guard checks signs and comparisons but does not strictly enforce integer row/column types. Positive fractional dimensions and booleans can pass the guard itself; a producer may impose its own stronger type validation. The constructor of the budget and the degree/horizon methods are stricter. Low-level exact matrix helpers do not automatically receive this budget, and `maximum_exact_entries` counts entries rather than their full rational payload.

Source: `coordinates/budget.py`. Complete field expressions and source SHA-256 values are in `Block43_Resource_Complexity_Index.json`.

ExpressionBudget

Field	Exact default
`max_nodes`	10,000
`max_depth`	1,000
`max_steps`	50,000
`max_degree`	512
`max_entries`	1,000,000
`max_coefficient_bits`	1,000,000
`max_serialized_bytes`	64,000,000
`max_symbol_length`	1,024

`preflight` performs a color-map traversal, rejects cycles and builds postorder. It checks `max_nodes` and `max_steps` only after this graph traversal; `max_steps` is `nodes+edges`, not executed CPU instructions or the cost of later matrix operations. Shared nodes count once, while repeated incoming edges still count. Depth, exact entries, polynomial degree, coefficient bits and symbol length are checked in subsequent structural passes.

`serialized_bytes` in `ExpressionStats` is deterministic structural accounting, not the size of a portable JSON envelope. The expression JSON reader separately measures actual UTF-8 bytes before `json.loads`. Obtaining, decoding and re-encoding the input text already takes memory. Expression normalization and recursive serialization have their own code paths and cannot be assumed safe at every permitted default depth merely because preflight itself is iterative.

Source: `expression/model.py`. Complete field expressions and source SHA-256 values are in `Block43_Resource_Complexity_Index.json`.

K.3 When the checks happen

Operation	Check timing
Finite-series constructor	After full iterable coercion
Finite-series output bit size	At result construction
Dense subset transform	Before matrix comprehension
Expression node/step counts	After graph traversal
Expression JSON byte length	Before JSON parsing, after text conversion
Packet-jet plan addresses	After complete enumeration
Snapshot basis evaluations	Before basis/evaluation loop
Snapshot dense elements	Before `np.zeros`
Stream selection	Before selected tuple construction
Height-bounded trees	After exact pre-count, before family generation
Leaf-bounded trees	After cached family generation
Pareto tree candidates	After child frontiers, before product plans
Weighted paths	After next path construction

Operation	Check timing
Modular recurrence period	Loop-bound guard

These distinctions are implementation facts, not reasons to remove guards. The safe response to a late check is to compute a cheap count before the call where possible, supply bounded inputs, retain smaller explicit caps, and keep untrusted or unpredictable callbacks in a separately controlled execution environment. Do not use `validate=False`, a truthy stored certificate flag, or a recomputed checksum as a resource or correctness workaround.

K.4 Source-derived complexity and storage models

The following **26 profiles** cover the principal dense, exact, packet, expression, enumeration and streaming families. The named-parameter census in K.8 is exhaustive under its stated pattern; these 26 reviewed algorithmic profiles are not an assertion that every one of the 1,526 API reference cards has a new complexity proof. Exact source fragments are preserved electronically rather than repeating implementation bodies in print.

K01 / Exact matrix product

Work model. Exactly a*b*c scalar product terms for (a,b) by (b,c); O(a*b*c) rational operations.

Storage model. a*c result entries plus input normalization copies; rational object payload is additional.

Derivation from source. Three nested row/column/inner-index traversals construct the result. Summing each dot product also performs b additions.

Guard and boundary. The low-level helper has shape validation but no CoordinateBudget argument. Exact scalar cost grows with numerator/denominator bit length.

Implementation: `coordinates/exact.py:matrix_multiply`, lines 97-114. SHA-256 `730ffa5075436ef26d9d65167c43073edd96971d14fe258fa94aef14556f8b0e`.

K02 / Exact row reduction and inverse

Work model. O(a*b*min(a,b)) rational elimination operations; square inverse O(n^3).

Storage model. O(a*b) rational entries; inverse uses an n by 2n augmented matrix.

Derivation from source. For each pivot, scan rows, normalize a row and eliminate other rows across the columns.

Guard and boundary. No global coefficient-bit or allocation budget in the low-level reducer. Intermediate fractions can be much larger than input fractions.

Implementation: `coordinates/exact.py:rref`, lines 157-184. SHA-256 `730ffa5075436ef26d9d65167c43073edd96971d14fe258fa94aef14556f8b0e`.

K03 / Exact matrix powers

Work model. O(log(e+1)) square matrix multiplications, hence O(n^3*log(e+1)) arithmetic work.

Storage model. O(n^2) live matrix entries up to constant-factor temporaries.

Derivation from source. Repeated squaring shifts the nonnegative exponent and multiplies the accumulating result on set bits.

Guard and boundary. This is an arithmetic-operation model. Integer/fraction growth can dominate; no claim of logarithmic bit complexity or tiny memory.

Implementation: `coordinates/exact.py:matrix_power`, lines 130-146. SHA-256 `730ffa5075436ef26d9d65167c43073edd96971d14fe258fa94aef14556f8b0e`.

K04 / Dense Boolean-lattice coordinates

Work model. 4^r matrix cells for rank r, before downstream exact matrix work.

Storage model. 4^r Fraction entries, stored in 2^r rows of length 2^r.

Derivation from source. The implementation builds every row/column pair; it is not an in-place fast subset transform.

Guard and boundary. CoordinateBudget checks dimension and entry product before the matrix comprehension. The default dimension 512 permits rank 9 but rejects rank 10; rank 9 is not benchmark-qualified here.

Implementation: `coordinates/combinatorial.py:subset_zeta_transform`, lines 315-350. SHA-256 `bb0a73e44deecfd2c64ea6c1418c38be7792d09d3106b22facda9dbf72c1dbc1`.

K05 / Formal-series convolution

Work model. (N+1)(N+2)/2 coefficient product terms through degree N; O(N^2) scalar operations.

Storage model. O(N) output and padded coefficient arrays, plus normalization/basis caches.

Derivation from source. For each n=0..N, every k=0..n contributes a structure constant times a[k] times b[n-k].

Guard and boundary. FormalSeries has no GeneratingBudget argument. A degree guard must be applied explicitly by the caller before invoking an expensive operation.

Implementation: `generating/series.py:FormalSeries.multiply`, lines 123-134. SHA-256 `e53da8fbe75432cffb8739880e1db7df027ce5abf9112f30b49afdbb5f2160af`.

K06 / Budgeted finite-series construction

Work model. O(L) domain coercions and coefficient bit checks for L supplied values.

Storage model. All L coerced coefficients are materialized before degree refusal.

Derivation from source. The tuple(domain.coerce(value) for value in coefficients) is constructed before require_degree(len(values)-1).

Guard and boundary. A small maximum_degree does not stop an infinite or excessively long input iterator. Supply an independently bounded iterable. Coefficient bits are recognized only for int/Fraction by the helper.

Implementation: `generating/finite_series.py:FiniteNormalizedSeries.__init__`, lines 102-125. SHA-256 `b31dab73da218f69ad5017f534ab75f632baa1198b953a688e8afca4b5397bb4`.

K07 / Finite normalized-series convolution

Work model. (N+1)(N+2)/2 terms, each two domain multiplications and one addition, excluding conversion.

Storage model. O(N) main arrays; output coefficient size is checked when the result is constructed.

Derivation from source. Nested n/k loops fill a finite output. Compatibility and basis conversion precede truncation guards.

Guard and boundary. Input/output degree caps do not bound intermediate scalar arithmetic. Other.convert can do work before an explicitly over-limit requested degree is rejected.

Implementation: `generating/finite_series.py:FiniteNormalizedSeries.multiply`, lines 280-308. SHA-256 `b31dab73da218f69ad5017f534ab75f632baa1198b953a688e8afca4b5397bb4`.

K08 / Formal composition, reciprocal and integer powers

Work model. Dense composition O(N^3); reciprocal O(N^2); repeated-squaring integer power O(N^2*log(e+1)).

Storage model. O(N) live coefficient buffers for each operation, excluding callback caches and scalar payload.

Derivation from source. Composition makes N+1 ordinary truncated convolutions of degree N; reciprocal uses triangular recurrence.

Guard and boundary. Zero entries can reduce convolution work but do not establish a subcubic worst-case composition algorithm. Basis gamma/structure-constant cost is separate.

Implementation: `generating/series.py:FormalSeries.compose`, lines 171-192. SHA-256 `e53da8fbe75432cffb8739880e1db7df027ce5abf9112f30b49afdbb5f2160af`.

K09 / Recurrence cache growth

Work model. From a cold cache, O(n*k) scalar work to index n for order k; repeated cached lookup O(1).

Storage model. O(n) retained terms after the highest requested index.

Derivation from source. The while loop appends every missing predecessor term before returning the requested index.

Guard and boundary. This term method is not logarithmic jumping. State/jump APIs are separate. Exact value sizes and an indefinitely retained cache matter.

Implementation: `arithmetic/recurrence.py:LinearRecurrence.term`, lines 163-173. SHA-256 `3374acced7d63e284f8b3ba7da6314bf44439ac7ea6ceea234ab006fd0185cbd`.

K10 / Finite modular recurrence period

Work model. For L nonrepeated states, O(L*k^2) matrix-vector work plus final determinant computation.

Storage model. O(L*k) state entries and O(k^2) companion entries.

Derivation from source. Each new state is stored in seen and advanced through a dense object matrix. The loop is range(limit+1).

Guard and boundary. Default max_steps is modulus^k+1, a mathematical finite bound, not a practical memory cap. Supply a smaller explicit max_steps for exploration.

Implementation: `arithmetic/recurrence.py:LinearRecurrence.period_mod`, lines 230-275. SHA-256 `3374acced7d63e284f8b3ba7da6314bf44439ac7ea6ceea234ab006fd0185cbd`.

K11 / Cartier automaton compile and lookup

Work model. S*p polynomial transitions for S reached states and prime p; scalar transition cost depends on degree. Query uses the base-p digits of n.

Storage model. O(S*p) transition indices plus O(S*D) stored state coefficients of width D.

Derivation from source. Every newly reached state gets one row of p transitions. Query follows a single precomputed state per digit.

Guard and boundary. The new-state guard runs after computing its candidate polynomial. Compilation, minimization and large-integer digit division are separate from query transition count.

Implementation: `generating/cartier.py:_reachable_automaton`, lines 214-268. SHA-256 `73ec9bbb8ef2b8d7e51e72d37757f1c9c63073a165b1e05e1b9a01ea7712ee56`.

K12 / Packet-axiom certificate

Work model. Exactly p^2 backend matrix products for p projectors; O(p^2*n^3) under a classical dense-product model.

Storage model. p*n^2 input entries and O(n^2) main temporary residuals.

Derivation from source. p idempotence products plus p*(p-1) cross-annihilation products.

Guard and boundary. Backend multiplication, norm and exactness rules determine actual cost. Certificate generation is work and can dominate cheap downstream operations.

Implementation: `core/packets.py:PacketSystem.certificate`, lines 92-136. SHA-256 `02427ff27728818c95e2e0d4d6d0f8dcdb3c8821a17fcf5cc63a312c4ad7cf31`.

K13 / Packet analysis

Work model. p dense matrix-vector applications; O(p*n^2) under the dense model.

Storage model. p*n ambient output entries in addition to* pn^2 stored projectors.

Derivation from source. Each projector is applied to the full input vector and all projected vectors are retained.

Guard and boundary. Packet decomposition does not automatically imply compressed storage. There is no per-call memory budget here.

Implementation: `core/packets.py:PacketSystem.analyze`, lines 154-159. SHA-256 `02427ff27728818c95e2e0d4d6d0f8dcdb3c8821a17fcf5cc63a312c4ad7cf31`.

K14 / Tensor products of packet systems

Work model. p*q Kronecker products, followed by validation of the resulting* pq projectors.

Storage model. p*q*(n*m)^2 scalar projector entries.

Derivation from source. The two projector loops form ambient Kronecker matrices and then invoke default PacketSystem construction.

Guard and boundary. Account for the additional (p*q)^2 products in validation. No tensor-specific allocation cap is applied before constructing the matrices.

Implementation: `core/packets.py:PacketSystem.tensor`, lines 220-234. SHA-256 `02427ff27728818c95e2e0d4d6d0f8dcdb3c8821a17fcf5cc63a312c4ad7cf31`.

K15 / Packet-jet family addresses and plan

Work model. A=q*p*^*r full addresses at order r; O(A*r) address payload before name lookup/grouping costs.

Storage model. O(A*r) active/pruned address records plus groups; retaining pruned records still costs memory.

Derivation from source. family.addresses() materializes all addresses before len(all_addresses)>max_addresses is tested. Grouping then retains active/pruned tuples.

Guard and boundary. max_addresses is a post-enumeration guard in R2. Name lookup, sorting and support partition checks add work. Predict q*p^r before calling.

Implementation: `nonlinear/execution.py:compile_packet_jet_plan`, lines 124-204. SHA-256 `474902031dcfa4066f4cc60b957489510b95d4d5ca9848ea9bc58844639f2158`.

K16 / Projection-cached packet-jet execution

Work model. Counts: r*p input projections, G derivative calls, A_active output projections, plus verification/direct work of the executor.

Storage model. Projected direction cache plus returned evaluations; backend/derivative workspace is extra.

Derivation from source. Grouping identical ordered input-packet tuples shares derivative evaluation across output packets. The built-in estimator reports G and A_active.

Guard and boundary. A call count is not a FLOP count. The derivative provider can be expensive or allocate its own tensor. The estimator compiles a plan unless one is supplied, so it is not a cheap universal preflight.

Implementation: `nonlinear/profiling.py:estimate_packet_jet_complexity`, lines 193-260. SHA-256 `034aa8498ddafce588627e5219ba80b7ee5950b512548f09503eff07263ab0de`.

K17 / Ambient snapshot capture

Work model. n^r jet evaluations of one fixed block, regardless of how many coefficients survive.

Storage model. O(n^2) ambient basis plus up to n^r records of r indices and m output scalars.

Derivation from source. The evaluator traverses the complete ambient Cartesian basis and omits coefficients only after evaluation and zero testing.

Guard and boundary. max_evaluations is checked before creating the basis and entering the evaluation loop. Sparse stored output does not mean sparse capture work.

Implementation: `nonlinear/snapshots.py:snapshot_packet_jet`, lines 280-368. SHA-256 `bd7a755c4b145b2fea23aeab89a1fa81e2d1fdcbe7117b365c0152b5e970d5d2`.

K18 / Snapshot dense expansion

Work model. Initialize m*n^r scalar cells and write all retained coefficient vectors.

Storage model. m*n^r scalar cells; numerical route uses complex dtype, exact route object pointers plus referenced objects.

Derivation from source. Shape is (target_dimension, source_dimension repeated order times).

Guard and boundary. max_elements is checked before np.zeros. Counting object array .nbytes is not the total memory of exact coefficients. Numerical default dtype is complex, not float64.

Implementation: `nonlinear/snapshots.py:PacketJetSnapshot.to_dense`, lines 205-222. SHA-256 `bd7a755c4b145b2fea23aeab89a1fa81e2d1fdcbe7117b365c0152b5e970d5d2`.

K19 / Streaming capture and materialization

Work model. Up to n^r evaluations, bounded per call by evaluation_budget; chunk I/O and manifest updates add work.

Storage model. Chunk coefficient buffers plus an expanding manifest, ambient basis, provider state and parsed JSON.

Derivation from source. Each loop commits at most chunk_size evaluations, then records progress. A pause is a valid incomplete stream.

Guard and boundary. chunk_size counts evaluations for capture, not bytes. Rewriting cumulative metadata can create superlinear metadata I/O as chunk count grows. max_coefficients guards selection/materialization, not arbitrary chunk byte size.

Implementation: `nonlinear/streaming.py:capture_packet_jet_stream`, lines 1010-1188. SHA-256 `b4db5f4d1493421b3b011167915735145c41bdbc5e8cdd64f63b6552bb6d0b90`.

K20 / Expression structural preflight

Work model. O(V+E+C) structural visits plus semantic-space and scalar text costs for a DAG.

Storage model. O(V+E) traversal state and coefficient/space witness temporaries.

Derivation from source. Color-map DFS builds postorder; node and step totals are checked only after traversal. Edges are counted even when child nodes are shared.

Guard and boundary. max_nodes is not an early traversal stop. max_steps is nodes+edges, not a CPU instruction budget. Structural serialized_bytes is not the final JSON envelope size.

Implementation: `expression/model.py:ExpressionBudget.preflight`, lines 580-676. SHA-256 `e01883acc993da14266dff0fd2518d8e9f045ef615a1094f3fbecc46b1ce4649`.

K21 / Expression JSON transport

Work model. O(B) byte counting/parse work plus decoded-tree and expression validation, where B is actual JSON bytes.

Storage model. Full input string/bytes, parse tree and expression objects may coexist.

Derivation from source. The UTF-8 size is checked before json.loads, but bytes decoding and text re-encoding already take memory.

Guard and boundary. Stricter than generic portable loads, yet not a process sandbox. A positive limit cannot constrain memory spent obtaining the input or allocations made before the length check.

Implementation: `expression/portable.py:expression_from_json`, lines 972-1010. SHA-256 `366c25d81842e91cbf228f84b10ad6626493d48eef3acad1129439cbdaf0e9d0`.

K22 / Height-bounded ordered trees

Work model. Exact count N_0=1, N_h=1+sum_{a in arities} N_(h-1)^a. Enumeration is output-sensitive.

Storage model. All generated tree objects/tuples are retained by unbounded lru_cache decorators.

Derivation from source. The count recurrence runs before tree generation and max_trees rejection for this height-based API.

Guard and boundary. Counting very large integers still consumes resources. max_trees is per requested family, not a cumulative cache cap. The separate leaf-count API checks after generation.

Implementation: `nonlinear/trees.py:ordered_rooted_trees`, lines 208-225. SHA-256 `94ce7611a8552386e3e8328bd9a9937a46efae730acf270feb99b9c37cb3aad4`.

K23 / Tree optimization versus resource budget

Work model. At most (B+1)^2 state-pair candidates per child merge, before plan-copy costs.

Storage model. Up to B+1 best plans per table; each plan retains leaves and decisions.

Derivation from source. B is quantized additive error allowance. Nested prior/child state loops enumerate feasible summed weights.

Guard and boundary. B is not a byte cap. O(V*B^2) is only the scalar DP-transition model; plan tuple copying can add up to O(V) per candidate. Lagrangian tree copying also prevents an unconditional linear-time Python claim.

Implementation: `algorithms/compiler.py:compile_tree_budget`, lines 140-243. SHA-256 `2bf95f61c84f3fd3f2256aaa3d02581c50cd5a81dab5c2a78565e0471621579f`.

K24 / Pareto tree enumeration

Work model. At a node, product of child frontier sizes candidates; pairwise frontier pruning can be quadratic in candidate count.

Storage model. All split plans plus keep plan and temporary sorted/frontier lists.

Derivation from source. max_plans is checked against the Cartesian product before materializing split plans, but after child frontiers exist.

Guard and boundary. The returned candidate set can include an extra keep plan. The guard is local, not total tree work or total byte accounting. Plan payload lengths matter.

Implementation: `algorithms/compiler.py:pareto_frontier`, lines 252-311. SHA-256 `2bf95f61c84f3fd3f2256aaa3d02581c50cd5a81dab5c2a78565e0471621579f`.

K25 / Krylov basis with orthogonality check

Work model. At most s operator applications; O(n*s^2) orthogonalization and final Gram check.

Storage model. O(n*s+s^2) numeric entries plus operator/provider workspace.

Derivation from source. Each new vector is projected against the existing basis. The final certificate forms Q*Q and an identity matrix.

Guard and boundary. The steps bound is 1..n, not a byte budget. Matrix-free input avoids storing a dense operator only if the callback does so.

Implementation: `algorithms/krylov.py:krylov_basis`, lines 41-85. SHA-256 `d6c5ae7cdd4ac9beabcda0fbdd4a16392b2d0f444145ecd9a3b64c2f4cda725d`.

K26 / Weighted-path enumeration

Work model. Output-sensitive generation with path-tuple copying, followed by sorting retained paths.

Storage model. Generated stack paths and retained output paths, each carrying all vertices and edges.

Derivation from source. The generated counter increments before the target-output filter and is checked after constructing the next path.

Guard and boundary. max_paths counts generated accepted-weight prefixes, not only paths ending at the requested target; None explicitly disables it. Positive weights control depth but not a polynomial count in precision.

Implementation: `refinement/weighted.py:WeightedTransferGraph.paths_below_weight,` lines 155-200. SHA-256 `94c13dd4ed26909c8cafffd2fcc88069d968ff38e5c7726b593316934553a012`.

K.5 Capacity tables without large allocations

The following figures are computed from shapes and element widths. They do **not** allocate the forecast objects and do not include extra working memory. One MiB is `2**20` bytes and one GiB is `2**30` bytes.

Dense shape	float64 payload	complex128 payload
`512 by 512`	2.0 MiB	4.0 MiB
`1024 by 1024`	8.0 MiB	16.0 MiB
`4096 by 4096`	128.0 MiB	256.0 MiB
`8192 by 8192`	512.0 MiB	1,024.0 MiB

A factorization, residual certificate, input conversion or temporary product can hold additional full matrices. These entries are payload sizes, not permission to fill the available memory completely. Exact object arrays have the same slot-count formula but a different referent cost.

Source n / target m / order r	Basis evaluations n^r	Dense cells m*n^r	complex128 payload
`4 / 4 / 4`	256	1,024	0.016 MiB
`8 / 8 / 4`	4,096	32,768	0.500 MiB
`32 / 32 / 4`	1,048,576	33,554,432	512.000 MiB
`64 / 64 / 4`	16,777,216	1,073,741,824	16,384.000 MiB

These are ambient tensor sizes, not packet-address counts. The default snapshot dense cap is ten million elements and would refuse the last two rows. Its numerical route uses complex cells. A higher explicit cap does not create memory or make the derivative provider cheaper.

Source packets p / target packets q / order r	Full family addresses q*p^r
`2 / 2 / 2`	8
`4 / 4 / 4`	1,024
`8 / 8 / 5`	262,144
`16 / 16 / 5`	16,777,216

Each address carries an ordered tuple and labels, not just a single integer. A predicted family exceeding the selected address cap should be rejected before calling the R2 plan compiler, whose own check follows enumeration. Even a pruned plan retains its pruned-address records. Support discovery and numerical zero testing are separate work, not free inputs to a sparsity claim.

K.6 Observed finite resource samples

The local profile uses Linux and `3.13.5 (main, Jun 25 2025, 18:55:22) [GCC 14.2.0]`, with NumPy `2.3.5`. Each record has one warmup and three measured repetitions, with thread-count environment variables set to one by the launcher. Inputs are constructed before profiling. Compilation/import time, cold caches and input construction are excluded. Timings include tracing overhead. No performance threshold is used to declare correctness.

Operation	Size	Median time (ms)	Median traced peak (bytes)
series	8	0.586215	3,520
series	16	1.609129	5,248
series	32	5.925964	8,808
exact matrix	4	0.247243	3,392
exact matrix	8	1.325661	6,208
exact matrix	12	4.028080	11,056
numpy matrix	16	0.027742	2,696
numpy matrix	32	0.025418	8,840
numpy matrix	64	0.057316	33,416

These nine workload records contain 27 timed samples. They are not nine asymptotic experiments or proof of an optimization. NumPy timings at these sizes can be nonmonotone because fixed costs and measurement noise dominate. The complete individual nanosecond and allocation samples, scope strings and environment are retained in `resource_replay/R36/result.json`. The final sealed-delivery replay records a new set of observations; it need not reproduce these measured values.

The library profiler uses `tracemalloc`, not peak process RSS or GPU memory. Native allocations may be outside its tracing scope, and an input created before tracing is not newly allocated inside the measurement. The profiler does not add general GPU synchronization. If a tracer is already active, it resets that tracer's peak and subtracts the starting baseline; that changes the outer peak statistic. Choose a separate profiling process when peak-statistic ownership matters. Object-buffer and referent sizes are demonstrated by R35.

K.7 Executed boundary probes and observations

All **36 probe expectations** below passed in bounded child processes against the separately installed build-2 wheel. Each process has active assertions and a 90-second wall timeout. Selected probes use counting iterators, wrappers, a parser sentinel, cache introspection or a custom finite expression node to observe order/counts. Such instrumentation is identified in the records and is not independent hardware qualification. No intentionally infinite iterable, huge allocation or uncontrolled recursion experiment is run. A passing probe may establish that a documented limit is permissive or late, not that the library is hardened.

R01 / Generating guard: require_degree

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=degree must be a nonnegative integer; type=ValidationError`.

Field: `maximum_degree`.

Limit: `4`.

Over: `message=degree 5 exceeds maximum_degree=4; type=ResourceLimitError`.

Zero allowed: `True`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R01 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R01/result.json`.

R02 / Generating guard: require_coefficient_bits

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=coefficient bit length must be nonnegative; type=ValidationError`.

Field: `maximum_coefficient_bits`.

Limit: `4`.

Over: `message=coefficient bit length 5 exceeds maximum_coefficient_bits=4; type=ResourceLimitError`.

Zero allowed: `True`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R02 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R02/result.json`.

R03 / Generating guard: require_matrix_dimension

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=dimension must be a positive integer; type=ValidationError`.

Field: `maximum_matrix_dimension`.

Limit: `4`.

Over: `message=matrix dimension 5 exceeds maximum_matrix_dimension=4; type=ResourceLimitError`.

Zero allowed: `False`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R03 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R03/result.json`.

R04 / Generating guard: require_states

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=states must be a positive integer; type=ValidationError`.

Field: `maximum_reachable_states`.

Limit: `4`.

Over: `message=state request 5 exceeds maximum_reachable_states=4; type=ResourceLimitError`.

Zero allowed: `False`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R04 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R04/result.json`.

R05 / Generating guard: require_local_combinations

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=combinations must be a positive integer; type=ValidationError`.

Field: `maximum_local_combinations`.

Limit: `4`.

Over: `message=local enumeration requires 5 combinations, exceeding maximum_local_combinations=4; type=ResourceLimitError`.

Zero allowed: `False`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R05 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R05/result.json`.

R06 / Generating guard: require_modulus

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=modulus must be a positive integer; type=ValidationError`.

Field: `maximum_modulus`.

Limit: `4`.

Over: `message=modulus 5 exceeds maximum_modulus=4; type=ResourceLimitError`.

Zero allowed: `False`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R06 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R06/result.json`.

R07 / Generating guard: require_serialized_bytes

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=serialized size must be a nonnegative integer; type=ValidationError`.

Field: `maximum_serialized_bytes`.

Limit: `4`.

Over: `message=serialized payload has 5 bytes, exceeding maximum_serialized_bytes=4; type=ResourceLimitError`.

Zero allowed: `True`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R07 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R07/result.json`.

R08 / Generating guard: require_terms

The standalone method accepts the exact limit and rejects limit+1. This alone does not prove all producers call it.

At limit: `4`.

Boolean: `message=term count must be a nonnegative integer; type=ValidationError`.

Field: `maximum_local_combinations`.

Limit: `4`.

Over: `message=term count 5 exceeds maximum_local_combinations=4; type=ResourceLimitError`.

Zero allowed: `True`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R08 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R08/result.json`.

R09 / Coordinate dimension boundary

A matrix cap is tested before a coordinate producer allocates its dense subset table.

Columns: `4`.

Refusal: `message=subset zeta transform requires a 8 by 8 matrix, exceeding the coordinate dimension limit 4; type=ResourceLimitError`.

Rows: `4`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R09 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R09/result.json`.

R10 / Coordinate entry-product boundary

Rows and columns can satisfy their separate caps while the entry-product cap still refuses the matrix.

At limit entries: `6`.

Refusal: `message=probe requires 9 exact entries, exceeding the coordinate entry limit 6; type=ResourceLimitError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R10 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R10/result.json`.

R11 / Coordinate degree and horizon

Both guards accept equality and reject one above their declared caps.

Degree: `message=probe degree 4 exceeds the coordinate degree limit 3; type=ResourceLimitError`.

Horizon: `message=probe horizon 5 exceeds the coordinate horizon limit 4; type=ResourceLimitError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R11 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R11/result.json`.

R12 / Coordinate matrix argument permissiveness

The low-level require_matrix method accepts positive floats and booleans; do not interpret it as a strict integer validator.

Boolean rows accepted: `True`.

Float rows accepted: `True`.

Negative: `message=matrix dimensions must be nonnegative; type=ValidationError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R12 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R12/result.json`.

R13 / Finite constructor consumes before degree guard

A finite counting iterator is exhausted before its over-degree construction is rejected. No unbounded iterator is run.

Consumed before refusal: `9`.

Degree limit: `3`.

Refusal: `message=degree 8 exceeds maximum_degree=3; type=ResourceLimitError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R13 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R13/result.json`.

R14 / Finite coefficient bit boundary

Fraction numerator and denominator bit lengths are capped on stored values, not on every arithmetic temporary.

Denominator: `message=coefficient bit length 5 exceeds maximum_coefficient_bits=4; type=ResourceLimitError`.

Numerator: `message=coefficient bit length 5 exceeds maximum_coefficient_bits=4; type=ResourceLimitError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R14 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R14/result.json`.

R15 / Stored generating byte cap is not generic codec enforcement

A generating budget survives serialization as data, while its tiny serialized-byte field does not automatically govern dumps_portable.

Actual envelope bytes: `3214`.

Declared bytes: `1`.

Roundtrip: `True`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R15 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R15/result.json`.

R16 / Stored generating recursion cap is not generic codec depth

The field maximum_recursion_depth is retained; generic portable depth uses its own argument.

Default codec roundtrip: `True`.

Stored maximum recursion depth: `1`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R16 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R16/result.json`.

R17 / Shared expression DAG count

Identity sharing lowers node count but repeated incoming edges still contribute to max_steps.

Refusal: `message=expression graph traversal exceeds max_steps; type=ResourceLimitError`.

Stats: `depth=2; exact_entries=1; maximum_coefficient_bits=1; maximum_degree=0; nodes=2; serialized_bytes=32; steps=4`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R17 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R17/result.json`.

R18 / Expression node cap is checked after graph traversal

Instrumented reads of child nodes confirm that a small over-limit DAG is still traversed before the node-count refusal.

Declared max nodes: `1`.

Refusal: `message=expression node count exceeds max_nodes; type=ResourceLimitError`.

Unique nodes visited: `9`.

Instrumentation: custom finite Expression children property; no patch to guard logic.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R18 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R18/result.json`.

R19 / Expression depth, symbol and coefficient guards

Small valid inputs and one-over inputs exercise separate structural limits.

Bits: `message=expression coefficient size exceeds max_coefficient_bits; type=ResourceLimitError`.

Depth: `message=expression depth exceeds max_depth; type=ResourceLimitError`.

Symbol: `message=symbol name exceeds max_symbol_length; type=ResourceLimitError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R19 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R19/result.json`.

R20 / Expression JSON bytes checked before parsing

A patched parser sentinel is not invoked when the actual input JSON exceeds the byte cap; UTF-8 counting still precedes that check.

Actual bytes: `282`.

Parser called: `False`.

Refusal: `message=expression JSON exceeds max_serialized_bytes; type=ResourceLimitError`.

Instrumentation: parser sentinel only.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R20 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R20/result.json`.

R21 / Formal multiply triangular operation count

Wrapping the real structure-constant method counts every emitted convolution term on a small dense input.

Degree: `7`.

Formula: `36`.

Product terms: `36`.

Instrumentation: method wrapper delegates to original.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R21 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R21/result.json`.

R22 / Finite multiplication output bit refusal

Small permitted input coefficients can produce an over-budget result, rejected only when the result constructor checks its bits.

Input bits: `3`.

Mathematical result: `49`.

Refusal: `message=coefficient bit length 6 exceeds maximum_coefficient_bits=3; type=ResourceLimitError`.

Result bits: `6`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R22 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R22/result.json`.

R23 / Packet certificate counts all pair products

The actual NumPy backend wrapper records p squared matrix products during the axiom certificate.

Matrix products: `4`.

Packets: `2`.

Instrumentation: backend method wrapper delegates to original.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R23 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R23/result.json`.

R24 / Plan address cap is post-enumeration

Wrapping the actual address generator records all eight returned addresses before a limit of one rejects the plan.

Addresses materialized: `8`.

Refusal: `message=packet-jet family has 8 addresses above max_addresses=1; type=ValidationError`.

Refusal limit: `1`.

Instrumentation: wrapper delegates to original address enumeration.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R24 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R24/result.json`.

R25 / Packet-jet count estimator and pruning

Source-derived counts match the finite grouped plan. Counts do not include a derivative callback complexity model.

Unpruned addresses: `8`.

Unpruned derivative calls: `4`.

Pruned active addresses: `2`.

Pruned derivative calls: `2`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R25 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R25/result.json`.

R26 / Snapshot evaluation cap precedes evaluation

A tiny snapshot refuses below n to the r evaluations and passes exactly at the bound.

Evaluations: `4`.

Refusal: `message=packet-jet snapshot requires 4 evaluations, exceeding 3; type=ValidationError`.

Stored coefficients: `4`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R26 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R26/result.json`.

R27 / Dense expansion count and dtype

The numerical snapshot dense route uses complex cells and guards element count, not bytes.

Dtype: `complex128`.

Itemsize: `16`.

Nbytes: `64`.

Refusal: `message=dense packet-jet expansion requires 4 elements, exceeding 3; type=ValidationError`.

Shape: `[1, 2, 2]`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R27 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R27/result.json`.

R28 / Stream pause, resume and coefficient materialization cap

Per-call work budgets produce incomplete valid streams; selection caps count entries, not file bytes.

Chunks: `3`.

Coefficients: `4`.

Complete: `True`.

Initial evaluations: `1`.

Refusal: `message=coefficient selection requires 4 entries, exceeding 3; type=ValidationError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R28 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R28/result.json`.

R29 / Height-tree pre-count refusal

A small exact recurrence predicts five trees at height two for binary arity. A cap of four is refused, while a cap of five succeeds.

Count: `5`.

Refusal: `message=tree family has 5 members, above max_trees=4; lower the height or raise the explicit limit; type=ValidationError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R29 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R29/result.json`.

R30 / Leaf-tree refusal leaves a populated cache

The leaf-count API builds the cached family before testing its length. Small binary trees expose that late check without large allocation.

Cache entries after: `4`.

Cache entries before: `0`.

Cached family size: `5`.

Refusal: `message=tree family has 5 members, above max_trees=1; lower the leaf count or raise the explicit limit; type=ValidationError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R30 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R30/result.json`.

R31 / Recurrence term retains predecessors

A single cold request to term(30) builds every preceding term; this API is not logarithmic random access.

Cache entries: `31`.

Index: `30`.

Value: `832040`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R31 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R31/result.json`.

R32 / Finite modular period search refusal

The explicit step budget can stop a finite search; its default state-space bound is not a memory promise.

Period: `3`.

Refusal: `message=period search exceeded max_steps before a state repeated; type=ValidationError`.

States checked: `3`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R32 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R32/result.json`.

R33 / Quantized tree budget is error allowance

Larger B can enable a cheaper plan. B is not a memory resource limit.

Two error cost: `1.0`.

Used units: `2`.

Zero error cost: `4.0`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R33 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R33/result.json`.

R34 / Pareto local combination limit

Two child frontiers create four candidate combinations; local max_plans=3 refuses before their product is materialized.

Combinations: `4`.

Frontier size: `4`.

Refusal: `message=Pareto enumeration would create 4 combinations, above max_plans; type=ValidationError`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R34 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R34/result.json`.

R35 / Object-array buffer does not include exact integers

Two equally shaped object arrays have equal pointer-buffer bytes despite different integer payload sizes.

Big referent sum: `352`.

Pointer bytes: `64`.

Small referent sum: `224`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R35 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R35/result.json`.

R36 / Finite observed scaling samples

Warm local timings and traced allocation peaks are observations, not asymptotic proofs, speedups or peak RSS.

Workload records: `9`.

Repetitions each: `3`.

Warmup each: `1`.

Reproduce: from a working copy with the pinned wheel installed, use `python tools/block43/run_probes.py --worker R36 --output <fresh-existing-scratch-directory>`. The all-probe launcher creates fresh directories and verifies package parity. Receipt: `manual/verification/block43-appendix-k/resource_replay/R36/result.json`.

K.8 Complete lexical parameter lookup

The index records **196 parameter declaration sites** matching `^(?:max_\|maximum_)\|(?:budget\|limit\|timeout)$\|^chunk_size$`. It scans all 300 package Python files, including verification helpers. Defaults are source expressions, not automatically resolved promises. Repeated `budget` arguments are distinct call surfaces. The list deliberately retains audit horizons, approximation denominator bounds, quantized error allowances and formatting limits; these are named limit candidates, not all memory caps. A size-controlling argument named only `degree`, `order`, `steps` or `shape` lies outside this syntactic census unless described in a reviewed profile.

algorithms/compiler.py

Callable / parameter	Declared default	Source line

The same source index retains 148 conditional-statement candidates mentioning these names, 58 named budget-method calls and 63 explicit `ResourceLimitError` raise sites. Exact fragments and coordinates are retained. Condition mentions are not control-flow proofs; variable names can be aliased or interpreted differently. A limit can raise `ValidationError`, `ValueError` or `RuntimeError` instead, or return an incomplete/negative record. Appendix I remains the exception reference. Source fragments are matched at line and column granularity, avoiding conflation of statements on one physical line.

K.9 Retained caches and cumulative memory

Source callable	Decorator
`generating/basis.py:WeightedMonomialBasis.gamma`	`lru_cache(maxsize=None)`
`generating/basis.py:q_factorial_basis.gamma`	`lru_cache(maxsize=None)`
`generating/basis.py:fibonacci_factorial_basis.fibonacci`	`lru_cache(maxsize=None)`
`generating/basis.py:fibonacci_factorial_basis.gamma`	`lru_cache(maxsize=None)`
`generating/basis.py:pochhammer_basis.gamma`	`lru_cache(maxsize=None)`
`nonlinear/autodiff.py:_probe_ad_framework`	`lru_cache(maxsize=2)`
`nonlinear/composition.py:set_partitions`	`lru_cache(maxsize=None)`
`nonlinear/sparse.py:_unique_permutations`	`lru_cache(maxsize=None)`
`nonlinear/trees.py:_ordered_rooted_trees_cached`	`lru_cache(maxsize=None)`
`nonlinear/trees.py:_positive_compositions`	`lru_cache(maxsize=None)`
`nonlinear/trees.py:_trees_with_leaves_cached`	`lru_cache(maxsize=None)`

Ten of the eleven explicit cache decorators use `maxsize=None`; the autodiff discovery probe uses two entries. No eviction bound is implied by the former. Some basis caches are attached to methods or closures and can retain arguments or objects through cache references. Tree/composition caches can retain combinatorial families even after a local result is discarded or a post-generation limit rejects it. Other ordinary mutable caches, such as the recurrence term list, are not decorator sites and are documented separately. Cache decorators are not an exhaustive inventory of every possible retained object.

Do not clear global/private caches blindly during another computation. Reproducible short-lived worker processes provide a clear lifetime for exploratory allocations. The leaf-tree probe clears only its dedicated worker's small cache before instrumentation. A shared long-lived production process needs an application-owned lifecycle policy and measurement; this manual does not introduce a new cache-management API.

K.10 A finite preflight worksheet

Before an expensive call, name its exact object, output cardinality, scalar type, possible temporaries, and limit enforcement phase. Calculate dimensions using Python integers before constructing arrays. For dense packet tensors compare `m*n**r` with the selected element limit and then multiply by the actual numerical dtype width. For packet plans compare `q*p**r` before plan compilation. For Boolean-lattice coordinates compare both `2**rank` and `4**rank` to the coordinate budget. For exact arrays reserve for coefficients and their intermediate growth, not just pointer buffers.

```
from math import prod

def dense_payload_bytes(shape, itemsize):
    shape = tuple(shape)
    if not isinstance(itemsize, int) or isinstance(itemsize, bool) or itemsize < 1:
        raise ValueError("itemsize must be a positive integer")
    if any(not isinstance(d, int) or isinstance(d, bool) or d < 0 for d in shape):
        raise ValueError("shape must contain nonnegative integers")
    return prod(shape) * itemsize

# A count only, not an allocation or a complete peak-memory estimate.
source_dimension, target_dimension, order = 32, 32, 4
shape = (target_dimension,) + (source_dimension,) * order
print(dense_payload_bytes(shape, 16))  # 536870912
```

When streaming, choose chunk size and per-call work budget separately. Verify the explicit completion flag before calling complete-snapshot operations. A coefficient cap is not a cap on input byte size, manifest size, individual exact values or decompression. Generic portable loaders parse the full envelope before their decoder depth checks; they do not inherit an embedded GeneratingBudget as a security policy. Consult Appendix G before reading external files.

A timeout is an observation/control on elapsed subprocess work, not a mathematical resource certificate. It does not retroactively prevent allocation, authenticate input, or necessarily terminate every external descendant. None of the recorded fixtures deliberately exhausts memory or proves behavior under memory exhaustion. Production RSS, allocator, filesystem and device limits must be configured outside these local mathematical budget dataclasses.

K.11 Reproduction, evidence, and completion boundary

The library source and both distributions remain exactly R2. The source suite passed 1,203 tests; the new source/-census/budget/reference suite passed 1,021 tests. All 36 active resource probe expectations passed. Those classes overlap and are not additive theorem counts. The 26 cost models are reviewed source-based derivations, not new Lean proofs. The separately installed wheel contains the same 366 package files; the full 901-file library payload is unchanged.

```
python tools/block43/inventory.py
python tools/block43/profiles.py
python tools/block43/run_probes.py --output <fresh-replay-directory>
```

```
python tools/block43/run_reference_tests.py
python tools/block43/run_source_tests.py
python tools/block43/generate_manual.py
python tools/block43/build_pdfs.py
python VERIFY_BLOCK43_PACKAGE.py
```

Regenerate only in a working copy. The default replay path is the recorded resource-evidence directory; move or archive old evidence first rather than overwriting its historical receipt. Tests and document generation require the active default replay to be present. The tools make no dependency downloads and reject source-checkout leakage for installed reference tests. Dependencies were inherited from the existing host environment, not installed into a fully dependency-isolated environment. Rebuilding or revalidating changes evidence and invalidates the outer archive hashes until a new reviewed delivery is made.

Reference boundaries. This version-bound resource reference supplies the stated lexical census, reviewed cost profiles and finite probes. It is not a universal resource-safety certificate, an exhaustive input or worst-case benchmark, a source-code repair or an end-to-end hardware qualification. The recorded audit did not qualify Windows/PowerShell, other Python versions, CUDA, strict MkDocs, fresh dependency-isolated installation or final publication. Portable-reader and certificate-validation limitations are documented separately. Appendix O identifies the final-source qualification records.

Appendix L covers migration and deprecation. The resource observations retain their original source, runtime and input bindings.

Appendix L. Migration and deprecation tables

This appendix is the migration reference for **Komorebi Math 1.0.0b4, Repair R2, wheel build 2**. It distinguishes a retained spelling, a delegating wrapper, an explicitly deprecated callable, a manifest compatibility result, a portable-codec migration and an executed package replacement. None of those categories by itself proves mathematical equivalence or qualifies every platform.

Reference scope. All 300 Python package source files are hashed. The index compares all 30 retained API-manifest files over each manifest's own namespace tuple and scans all 1,526 current export records for deprecation metadata. It records 22 direct function/class assignment aliases, five explicitly documented wrapper aliases, three literal selector-alias maps and 131 stable export identities in two versioned facades. The 1,526 count includes repeated objects exported at different routes. The alias census deliberately excludes coincidental constant equality and arbitrary caller-defined aliases.

Execution scope. Five stored predecessor wheels were genuinely installed one at a time in disposable environments. Each wrote two portable records, then was replaced by the pinned R2 wheel. Both records loaded unchanged, the complete fifteen-check upgrade contract passed and all ten stable semantic cases executed for each path. Thirty additional migration/deprecation probe expectations and 572 reference tests passed. Dependencies were inherited, not freshly resolved in a clean environment.

Identify what is being migrated. An import spelling, a function call, an installed package and a saved object require different checks. Use the route below before making a replacement.

Change you are considering	Read	What to compare
Adopt a clearer name for an existing object	L.6 and L.7	Object identity versus wrapper behavior, including keyword names
Move an import to a stable namespace	L.2 and Appendix A	Whether that exact export belongs to the stable tier
Upgrade the installed package	L.3, L.11 and L.12	Actual distribution, environment, application results and retained rollback inputs
Load an older portable object	L.10 and Appendix G	Codec tag, adjacent migration path and reconstructed value

Make one kind of change at a time when diagnosing compatibility. Keep a small application example with its expected values, shapes and certificate interpretation, and run it in a fresh process after replacing the package. A manifest comparison helps locate interface differences; the application example checks the particular behavior you depend on. Keep the original saved data until the migrated copy has passed the checks appropriate to that object.

L.1 Status vocabulary and admission rules

Record class	Meaning in this release	What it does not establish
Identity alias	Two exported Python names refer to the same object.	A removal date, deprecation warning or alternative implementation.
Delegating wrapper	A function/property forwards to another implementation.	Identical Python keyword names or object identity.
Explicit deprecation	A callable carries `__komorebi_deprecation__` metadata and a warning wrapper.	Automatic removal, a validated version ordering or visible warnings under every filter.

Record class	Meaning in this release	What it does not establish
Structural comparison	Selected names, broad kinds and optionally signature text match policy.	Equivalent implementations or all application behavior.
Exact stable freeze	The selected upgrade path also has no added exports or unapproved signature drift.	Future indefinite support or native-platform qualification.
Portable migration	An adjacent versioned decoder-data transformation exists.	Pickle compatibility, downgrade capability, proof checking or malicious-input hardening.
Executed replacement	A predecessor install was actually replaced and finite records were replayed.	All old scripts, all dependency versions or every application dataset.

No declared export in the reference baseline has a `__komorebi_deprecation__` record. No @deprecated application appears in the scanned package source. The one direct warn_deprecated call is inside the generic decorator wrapper itself. The utility exists, but this snapshot does not contain a removal schedule for a concrete current export. The zero-metadata census records this baseline; it is not a promise about future releases.

L.2 Select the API tier before migrating

Tier	Current export records	Pinned policy
Stable	131	Frozen signatures, explicit semantic fixtures and persistence/upgrade contracts.
Beta	83	Curated additive surface with strict signature checks.
Research	1312	Broad research surface with an additive compatibility checker; request strict signatures explicitly.

Moving a name from a broad namespace to stable is appropriate only when the name is actually exported there. A broad research name is not promoted by changing an import string. Keep experimental code explicitly tied to its package snapshot and verify its inputs and outputs. The current stable surface is available through three import styles:

```
from komorebi_math import stable
from komorebi_math import v1
from komorebi_math.api import v1 as api_v1

assert set(stable.__all__) == set(v1.__all__) == set(api_v1.__all__)
assert all(getattr(stable, name) is getattr(v1, name)
           is getattr(api_v1, name) for name in stable.__all__)
```

The identity assertion is about exported values, not module object identity. Choose one style consistently. A successful reflection check does not authorize changing persisted Python implementation paths by hand.

L.3 Predecessor versions and exact stable deltas

The shipped contract targets 1.0.0b4 and names **0.15.0a2, 0.16.0a2, 1.0.0b1, 1.0.0b2 and 1.0.0b3**. The old UPGRADE_CONTRACT.md prose lists only the first two and describes a 1.0.0b1 target. This appendix supersedes that outdated coverage statement without rewriting historical library documentation.

Predecessor	Stable exports	Added	Signatures changed	Contract rule
0.15.0a2	72	59	1	Allowed named migration
0.16.0a2	131	0	0	Exact unchanged freeze
1.0.0b1	131	0	0	Exact unchanged freeze
1.0.0b2	131	0	0	Exact unchanged freeze
1.0.0b3	131	0	0	Exact unchanged freeze

There are no removed exports or broad kind changes in these five stable comparisons. The 0.15.0a2 path adds 59 names and changes create_stable_api_manifest from a baked-in package-version default to package_version=None. Its single signature change is explicitly allowed by the upgrade checker. The other four stable baselines are exactly unchanged at 131 names. A raw strict comparator will still reject the 0.15 signature difference; that is expected and distinct from the explicit upgrade allowance.

Stable additions relative to 0.15.0a2. These are additions, not replacements for removed names. Appendix A gives their full API records.

L.4 All retained API-manifest comparisons

The table covers every retained API-manifest JSON file, including unversioned current copies that duplicate versioned snapshots. The electronic index identifies exact filenames and SHA-256 digests; these thirty files do not represent thirty distinct releases. A historical research manifest may cover fewer namespaces than the current research manifest. Each comparison reflects the recorded package over exactly the old tuple and never mixes unmatched scopes.

ID	Version	Tier	Old / current	Added / removed / signature	Strict
A01	0.10.0a1	research	464 / 723	259 / 0 / 2	no
A02	0.11.0a1	research	528 / 723	195 / 0 / 3	no

A30	1.0.0b4	stable	131 / 131	0 / 0 / 0	yes

All thirty comparisons have zero removals and zero broad kind changes. Strict failures record real signature-text differences, not necessarily broken calls. Early research manifests retain old namespace defaults and version defaults for manifest builders. Six tuple-based public type aliases changed recorded signature text from (iterable=(), /) to (*args, **kwargs) under the package's portable normalization. That change is not evidence of a different mathematical representation. Do not edit historical snapshots merely to remove a reported difference.

The full row-by-row additions, removals, kind differences and old/new signature text are in `Block44_API_Migration_Differences.tsv`. It contains 1671 comparison rows, including repeated changes against different historical baselines. Appendix C remains the semantic/API reference for current research symbols.

L.5 Signature changes that require review

Manifest builders now use package_version=None to select the running package version. Supplying an explicit version labels a manifest; it does not install that version or prove its behavior. The broad builder's default namespace tuple expanded as the library grew. Pass an explicit tuple when comparing a historical research surface. Stable and beta builders retain their dedicated namespace contracts.

Route family	Historical difference	Migration action
create_public_api_manifest	Default namespaces expanded; literal version default became None.	Pass the exact desired namespaces and run a separately selected strict policy.
create_beta_api_manifest	Literal version default became None.	Allow runtime version selection, or provide an intentional metadata label.
create_stable_api_manifest	0.15 literal version default became None.	Use the named 0.15 upgrade allowance; retain semantic and persistence checks.
Partition; Matrix; ModularMatrix; ModularVector; Polynomial; Vector	Tuple-based generic alias signature normalization changed.	Treat these as shared type aliases, not automatically as custom domain constructors. Test the actual values your code uses.
shannon_entropy_cost to entropy_cost	Wrapper second keyword is path, canonical second keyword is _.	Use positional second arguments or adjust the keyword intentionally.
projector to component	Wrapper name can overstate idempotence for redundant systems.	Use component terminology and independently establish any required projector laws.

L.6 Explicit identity-alias table

Every following assignment is source-bound and object-identical at runtime. The arrow follows the assignment direction, not a chronology of removal. Some aliases are present in multiple public namespaces. None is decorated as deprecated. The complete source file, line range and checksum are in the electronic record.

L-A01 / NormalizedBasis

`komorebi_math.coordinates.normalized.NormalizedBasis = komorebi_math.coordinates.normalized.WeightedMonomialBasis`. Identity checked in the separately installed R2 package. Source: `komorebi_math/coordinates/normalized.py` line 19; SHA-256 prefix `e92de85740e2`.

L-A02 / ExactCoordinateTransform

`komorebi_math.coordinates.transform.ExactCoordinateTransform = komorebi_math.coordinates.transform.CoordinateTransform`. Identity checked in the separately installed R2 package. Source: `komorebi_math/coordinates/transform.py` line 151; SHA-256 prefix `1e02b12f4797`.

L-A03 / RationalMemoryKernel

`komorebi_math.dynamics.memory.RationalMemoryKernel = komorebi_math.dynamics.memory.MemoryKernel`. Identity checked in the separately installed R2 package. Source: `komorebi_math/dynamics/memory.py` line 130; SHA-256 prefix `9a63a0123887`.

L-A04 / ProjectiveSemigroupTower

`komorebi_math.dynamics.semigroups.ProjectiveSemigroupTower = komorebi_math.dynamics.semigroups.FiniteSemigroupTower`. Identity checked in the separately installed R2 package. Source: `komorebi_math/dynamics/semigroups.py` line 311; SHA-256 prefix `3e905fdef4dc`.

L-A15 / FinitePolyphaseKernel

`komorebi_math.signals.FinitePolyphaseKernel = komorebi_math.signals.PolyphaseBlockMatrix`. Identity checked in the separately installed R2 package. Source: `komorebi_math/signals/__init__.py` line 195; SHA-256 prefix `6f57c41ee2ae`.

L-A16 / finite_polyphase_filter_kernels

`komorebi_math.signals.finite_polyphase_filter_kernels = komorebi_math.signals.finite_polyphase_blocks`. Identity checked in the separately installed R2 package. Source: `komorebi_math/signals/__init__.py` line 196; SHA-256 prefix `6f57c41ee2ae`.

L-A17 / TruncatedPowerPacket

`komorebi_math.signals.singular_packets.TruncatedPowerPacket = komorebi_math.signals.singular_packets.TruncatedPowerTerm`. Identity checked in the separately installed R2 package. Source: `komorebi_math/signals/singular_packets.py` line 104; SHA-256 prefix `856d0f073989`.

L-A18 / RetainedPacketReconstruction

`komorebi_math.signals.singular_packets.RetainedPacketReconstruction = komorebi_math.signals.singular_packets.RetainedPacketResult`. Identity checked in the separately installed R2 package. Source: `komorebi_math/signals/singular_packets.py` line 202; SHA-256 prefix `856d0f073989`.

L-A19 / polyphase_refine

`komorebi_math.stable.polyphase_refine = komorebi_math.stable.refine_polyphase`. Identity checked in the separately installed R2 package. Source: `komorebi_math/stable.py` line 161; SHA-256 prefix `8fc11ed02b89`.

L-A20 / polyphase_coarsen

`komorebi_math.stable.polyphase_coarsen = komorebi_math.stable.coarsen_polyphase`. Identity checked in the separately installed R2 package. Source: `komorebi_math/stable.py` line 162; SHA-256 prefix `8fc11ed02b89`.

L-A21 / lattice_polyphase_refine

`komorebi_math.stable.lattice_polyphase_refine = komorebi_math.stable.refine_lattice_polyphase`. Identity checked in the separately installed R2 package. Source: `komorebi_math/stable.py` line 163; SHA-256 prefix `8fc11ed02b89`.

L-A22 / lattice_polyphase_coarsen

`komorebi_math.stable.lattice_polyphase_coarsen = komorebi_math.stable.coarsen_lattice_polyphase`. Identity checked in the separately installed R2 package. Source: `komorebi_math/stable.py` line 164; SHA-256 prefix `8fc11ed02b89`.

The CuPy capitalization and descriptive aliases can be checked without allocating a GPU object. This establishes only Python identity. It is not evidence that CuPy is installed, a driver works, or a CUDA computation passed. The original Cupy spellings are retained; replacing their imports is optional readability work, not an announced forced migration.

L.7 Delegating wrappers and semantic naming

Retained entry point	Current destination	Boundary
AnalysisSynthesisSystem.projector	component	Value delegation, not independent proof of idempotence.
AnalysisSynthesisSystem.projectors	components	Returns additive reconstruction maps for redundant frames.
HaarPacketTree.decompose	analyze	Classmethod delegation with the same finite-input conditions.
HaarPacketTree.coefficients	nodes	Shallow mapping copy; contained arrays are not newly deep-copied.
shannon_entropy_cost	entropy_cost	Positional semantics agree; second keyword spelling differs.

For the analysis matrix A with rows (1,0), (0,1), (1,1), the canonical dual constructs a valid redundant reconstruction system. Its components sum to I, yet its first component is not idempotent. Both the old projector spelling and the preferred component spelling return that same map. A name change does not repair a missing mathematical hypothesis.

```
import numpy as np
from komorebi_math.coordinates.analysis_synthesis import AnalysisSynthesisSystem

A = np.array([[1., 0.], [0., 1.], [1., 1.]])
system = AnalysisSynthesisSystem.canonical_dual(A)
part = system.component(0)
assert np.allclose(part, system.projector(0))
assert np.allclose(sum(system.components()), np.eye(2))
assert not np.allclose(part @ part, part)
```

This is a finite numerical fixture at the recorded tolerance. The check is not a theorem for all floating inputs. Use Appendix H to understand the separate certificate interfaces, and do not bypass validation to make a migration appear successful.

L.8 Textual selector aliases

Selector spellings are not Python-object aliases or deprecations. Three source-local alias dictionaries retain the following spellings. Their surrounding normalization is part of the contract: sequence/window selectors strip whitespace, lowercase and replace underscores with hyphens; polynomial-family selection uses its separately normalized short-name lookup. The table is the exact literal-map census, not every normalized spelling a user can construct.

Selector owner: `komorebi_math.coordinates.classical.PolynomialFamilyCatalog.get`.

Accepted alias	Destination key
bernoulli	bernoullipolynomials
binomial	binomialpolynomials
chebyshevt	chebyshevtpolynomials
chebyshevu	chebyshevupolynomials
euler	eulerpolynomials
falling	fallingfactorials
fibonacci	fibonaccipolynomials
hermitephysicists	physicistshermitepolynomials
hermiteprobabilists	probabilistshermitepolynomials
laguerre	laguerrepolynomials
legendre	legendrepolynomials
lucas	lucaspolynomials

Accepted alias	Destination key
`monomial`	`monomials`
`pell`	`pellpolynomials`
`rising`	`risingfactorials`

Selector owner: `komorebi_math.sequences.catalog.get_sequence`.

Accepted alias	Destination key
`apery-zeta3`	`apery`
`euler-zigzag`	`zigzag`
`signed-euler`	`euler`
`thue-morse`	`thue-morse`
`thuemorse`	`thue-morse`

Selector owner: `komorebi_math.signals.windows._canonical_name`.

Accepted alias	Destination key
`hanning`	`hann`
`ones`	`boxcar`
`rect`	`boxcar`
`rectangle`	`boxcar`
`rectangular`	`boxcar`
`triang`	`bartlett`
`triangle`	`bartlett`

The thue-morse self-map is an explicit dictionary entry, not a new function. Finite probes compare each sequence alias on the first five terms, polynomial aliases by selected family identity/name, and window aliases by canonical selector. These checks do not make window boundary conventions or polynomial normalization interchangeable across different families.

L.9 Deprecation utility protocol

Field	Meaning	Enforcement
since	First announced deprecation version label.	Stripped and required to be nonempty; not parsed as a release version.
replacement	Suggested alternate callable name.	Optional text; existence or equivalence is not checked.
remove_in	Planned removal label.	Metadata only; no automatic removal.
reason	Explanation of the change.	Optional text added to warning output.

The wrapper exposes `__komorebi_deprecation__`, preserves `__wrapped__` and uses functools.wraps. A normal finite callable retains its reflected signature and delegates arguments and return value. The wrapper does not implement a version clock. Do not rely on it to disable dangerous behavior or execute a removal policy automatically. The generic helper accepts any callable, but the finite tests do not establish transparent class, generator, descriptor or async transformation for all callable forms.

```
import warnings
from komorebi_math import deprecated, KomorebiDeprecationWarning

# Synthetic example, not a newly deprecated library export.
@deprecated(since="0.10", replacement="new_function", remove_in="0.11")
def old_function(value: int) -> int:
    return value + 1

with warnings.catch_warnings(record=True) as caught:
    warnings.simplefilter("always", KomorebiDeprecationWarning)
    assert old_function(2) == 3
    assert len(caught) == 1
```

Warning filters materially affect control flow. Under ignore, the body runs without a recorded warning. Under error, the warning becomes an exception before the body runs. The decorator's observed stacklevel points into compatibility.py, not the external caller. A direct call to warn_deprecated has different stack depth. Test warning category and metadata rather than assuming every displayed filename is the application call site.

A deprecation decision still needs a named symbol, reason/replacement, first warning label, announced removal label when known, persistence and CLI impact, test evidence and manifest differences. The retained policy permits exceptions for correctness/security/packaging defects, but this appendix does not create such a removal or change licensing permissions.

L.10 Portable version migration and file preservation

Python import names, package versions, outer envelope schema versions, individual codec versions and wheel build tags are independent identities. Changing one does not migrate the others. Appendix G provides the complete codec-field reference. This appendix supplies the operational upgrade direction and rollback boundaries.

Format or record	Migration status	Action
nonlinear.packet_jet_snapshot, codec 1 to 2	Single built-in adjacent migration.	Rename provider_name to provider, set coefficient_ordering to lexicographic and retain the other declared values through decoding.
Seven committed 0.15/0.16 portable fixtures	Current reader reconstructs all seven with bound type and payload digest.	Retain producer_version and original bytes.
Ten newly generated records from five predecessor installs	All loaded after actual replacement with R2.	Keep originals separately; newly saved envelopes identify the current producer.
Caller-defined codec with multiple older versions	Every adjacent forward edge is required.	Register migrator= functions and test missing/broken/future edges.
Pickle, undocumented implementation objects, third-party codecs	Excluded from shipped upgrade contract.	No generic upgrade or reverse compatibility claim.

The built-in snapshot edge acts on already decoded codec data. The valid registration keyword is **migrator=**, not migrate=. A direct edge that skips a version is rejected. Missing or failing migrations return failures; future versions are not automatically accepted. No built-in downgrade edge is present. A v2 record cannot be made v1 merely by editing `__version__`.

Keep original files immutable and write migrated output into a new destination. Save/load overwrite checks and payload hashes are useful corruption controls, not authenticity guarantees. The payload digest excludes producer metadata, and loading stored certificates is not proof validation. Neither this appendix nor a successful upgrade fixes the permissive decoder and certificate boundaries recorded in Appendices G-H.

L.11 Executed wheel-to-wheel upgrades

Installed predecessor	New portable records	Replacement target	Observed result
0.15.0a2	2	1.0.0b4 / build 2	Load originals + 15 upgrade checks + 10 semantic cases
0.16.0a2	2	1.0.0b4 / build 2	Load originals + 15 upgrade checks + 10 semantic cases
1.0.0b1	2	1.0.0b4 / build 2	Load originals + 15 upgrade checks + 10 semantic cases
1.0.0b2	2	1.0.0b4 / build 2	Load originals + 15 upgrade checks + 10 semantic cases
1.0.0b3	2	1.0.0b4 / build 2	Load originals + 15 upgrade checks + 10 semantic cases

Each row used a newly created temporary environment. The predecessor wheel was installed with –no-index –no-deps, its imported version and metadata were checked, and every installed package file was compared against that wheel. It then created PolyphaseRefinement(4,12) and PolyphaseRefinementTower((2,6,24)) portable files. After a real pip replacement, a fresh Python process verified R2 version and package-byte parity, loaded both original records and executed the current contract and stable semantic cases. Both before/after workers recorded package-module origins.

The refinement children for residue 1 are (1,5,9), and the tower orders remain (2,6,24). Those finite values and original envelope bytes matched across all five paths. The ten files are newly generated upgrade observations, not ten distinct mathematical algorithms. The seven committed historical fixtures are additional inputs already inside the fifteen-check contract; do not add repeated checks as independent proofs.

The environments inherited existing external dependency paths. Thus these are actual package replacements with package-byte/origin checks, not a newly resolved dependency matrix. Only Linux and the recorded CPython environment were exercised. The stored predecessor wheels remain byte-for-byte unchanged and their archival hashes are included in the migration index.

L.12 Same-version wheel builds, process restart and rollback

The public version remains 1.0.0b4, while the repaired distribution filename carries wheel build tag 2 and the release identity is 1.0.0b4-block36-r2. Version text alone cannot distinguish the stale original b4 wheel from R2. Pin the actual artifact hash and use an explicit replacement when an old same-version wheel may already be installed.

```
python -m pip install --no-index --no-deps --force-reinstall \
  release/dist/komorebi_math-1.0.0b4-2-py3-none-any.whl
```

The command assumes the required dependencies are already available. On PowerShell, enter it as one line rather than copying the POSIX continuation backslash. Native PowerShell execution is not claimed. Perform the replacement in the intended environment, then restart the Python process or notebook kernel before importing the new code. Replacing files on disk is not a supported way to migrate objects already retained in a running interpreter.

For rollback, retain the predecessor wheel, its hashes, environment description, application requirements and original portable records outside the upgrade environment. Recreate a separate prior environment and read original records there. The recorded forward tests do not establish that a predecessor can read a newly written R2 envelope or a newly introduced codec. Do not overwrite an original with an unqualified downgrade. Avoid mixing old and new object instances in one process.

L.13 Contract checks and caller-controlled coverage

A custom path accepted by check_upgrade_contract changes the set of checks performed. The reduced-contract probe deliberately supplied no fixtures and an empty predecessor list; the remaining checks passed. That is not evidence for the omitted records. A consumer requiring the shipped contract must independently pin its file digest and require five predecessor names, seven fixture records, five stable baselines and fifteen executed checks.

The ordinary strict API comparator is additive: additions are allowed, while removed exports, broad kind changes and signature changes fail. The stable predecessor upgrade branch imposes the stronger no-additions freeze for every predecessor except the specifically allowed 0.15 migration. Changing implementation_module or qualname alone does not fail compare_public_api. Stable semantic fixtures and your own regression examples therefore remain essential.

```
from komorebi_math.release import check_upgrade_contract
from komorebi_math.stable_semantics import run_stable_semantics_fixture

report = check_upgrade_contract()
assert report.contract.target_version == "1.0.0b4"
assert len(report.contract.predecessor_versions) == 5
assert len(report.contract.fixtures) == 7
assert len(report.checks) == 15
assert report.passed
assert run_stable_semantics_fixture().certificate.valid
```

These assertions expose the intended inventory but are not an authenticated trust anchor. Use a trusted release checksum for the contract and wheel, and preserve the actual result record. A checksum published by the same untrusted writer is not authentication. The report's stored validity flag is not a Lean proof.

L.14 Complete stable-facade identity ledger

For every name below, both versioned namespaces refer to the same value as komorebi_math.stable. The table is a complete 131-name identity ledger. It does not expand the frozen stable API with research-only symbols.

L.15 Executable migration and deprecation recipes

All thirty cases execute in fresh bounded subprocesses against the pinned installed wheel. The cases include expected exceptions, permissive-boundary observations and synthetic metadata controls. A passed expectation is not always a positive compatibility or security qualification. Full inputs, result records, tracebacks for failed attempts and module-origin records are retained in the verification directory.

M01 / Complete shipped upgrade contract

Runs the complete shipped contract: five stable manifest baselines, one semantic continuity check, one codec continuity check, seven digest-bound portable fixtures and target identity. Fifteen checks pass. Read the inventory and unchecked assumptions, not only the Boolean result.

Executed evidence: `migration_replay/M01/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M02 / Execute the ten stable semantic fixtures

Actively computes all ten current stable semantic cases. This is separate from the upgrade checker, whose semantic continuity step compares stored fixture content and digests. The active finite cases are not a proof of every input.

Executed evidence: `migration_replay/M02/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M03 / Reject a wrong target version

Changing only the target version produces a failed target-identity check. The fixture does not alter the installed package version to make a stale contract appear current.

Executed evidence: `migration_replay/M03/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M04 / Reject a changed fixture checksum

A changed expected source-file checksum is rejected even when the actual fixture is otherwise valid. Restore an independently retained correct original instead of updating the checksum to conceal corruption.

Executed evidence: `migration_replay/M04/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M05 / Reject a wrong reconstructed type

A deliberately wrong reconstructed Python type is rejected. Portable equality, type identity and producer metadata are separate checks.

Executed evidence: `migration_replay/M05/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M06 / Reduced caller contract can pass with less coverage

A caller-supplied contract with an empty predecessor list and no portable fixtures still passes its remaining checks. Passing does not enforce that the caller selected the shipped coverage. Pin the contract file hash and require the expected five predecessors, seven fixtures and fifteen checks.

Executed evidence: `migration_replay/M06/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M07 / Reject removed exports

Removing a stable export in a synthetic manifest fails both ordinary and strict compatibility. This tests the comparator, not a modified installation.

Executed evidence: `migration_replay/M07/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M08 / Reject broad kind changes

Changing a broad symbol kind fails both policies. The fixture changes metadata only and does not claim to exercise an alternative implementation.

Executed evidence: `migration_replay/M08/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M09 / Signature strictness is explicit

A changed signature is reported by both policies but fails only with strict_signatures=True. The ordinary additive certificate can be true with signature differences.

Executed evidence: `migration_replay/M09/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M10 / Implementation identity is not a compatibility check

Changing only implementation_module and qualname in a synthetic manifest leaves strict compatibility true. The comparator does not inspect implementation equivalence. Use semantic fixtures and application tests separately.

Executed evidence: `migration_replay/M10/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M11 / Additive symbols remain structurally compatible

Adding a new exported symbol passes ordinary and strict additive comparison. A stronger exact-freeze gate must additionally require an empty added set.

Executed evidence: `migration_replay/M11/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M12 / Decorated call retains arguments and metadata

A synthetic deprecated function preserves its inspect.signature, `__wrapped__`, arguments, return value and deprecation record. The always warning filter records the warning. This is a fixture, not a newly deprecated library export.

Executed evidence: `migration_replay/M12/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M13 / Warnings-as-errors blocks the body

The error warning filter turns the warning into an exception before the wrapped function body runs. A test that elevates warnings can therefore change control flow.

Executed evidence: `migration_replay/M13/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M14 / Warning filters may suppress output

The ignore filter suppresses the warning while the wrapped function continues to run. Absence of visible warnings is not evidence that deprecation metadata is absent.

Executed evidence: `migration_replay/M14/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M15 / Removal metadata and warning source location

The recorded remove_in version does not disable the callable. The decorator uses stacklevel=2 inside its wrapper, and the observed warning points into compatibility.py rather than the external call site. Do not treat that location as the application caller.

Executed evidence: `migration_replay/M15/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M16 / Reject malformed deprecation setup

Blank since text, a noncallable decoration target and a blank direct warning name are rejected. These are small utility validation checks, not a complete semantic version parser.

Executed evidence: `migration_replay/M16/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M17 / Version labels are not a scheduler

Nonempty non-version strings are accepted as since and remove_in labels. The utility does not order versions, validate a release calendar, or enforce a removal deadline.

Executed evidence: `migration_replay/M17/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M18 / Redundant projector wrapper is not idempotent

The redundant canonical-dual fixture returns equal values from projector and component, but the component is not idempotent. Components sum to the identity. No deprecation warning is emitted. Use component terminology unless idempotence is established independently.

Executed evidence: `migration_replay/M18/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M19 / Wavelet wrapper and keyword boundary

HaarPacketTree.decompose delegates to analyze, coefficients exposes the nodes mapping, and shannon_entropy_cost matches entropy_cost positionally. The wrapper accepts path= while the canonical entropy_cost second parameter is named _. A blind keyword-preserving rename can fail.

Executed evidence: `migration_replay/M19/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M20 / All explicit object aliases

Every one of the twenty-two explicit module-level function/class assignment aliases is object-identical to its source name. Class identity does not require constructing a GPU executor and does not qualify CUDA.

Executed evidence: `migration_replay/M20/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M21 / All versioned stable aliases

All 131 stable exports are identical to their counterparts in both komorebi_math.v1 and komorebi_math.api.v1. Namespaces themselves remain different module objects.

Executed evidence: `migration_replay/M21/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M22 / Actual snapshot v1 to v2 migration

Loads the genuine version-1 packet-jet snapshot fixture retained in Appendix G and re-encodes it as codec version 2. Original data stays immutable; the new record supplies provider and lexicographic ordering.

Executed evidence: `migration_replay/M22/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M23 / Missing custom migration chain is refused

A custom version-3 codec cannot decode version-1 data when the adjacent migration chain is missing. This synthetic codec is local to a disposable probe process.

Executed evidence: `migration_replay/M23/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M24 / Future codec version is refused

A future codec version is refused. There is no automatic reverse migration or undocumented future-version acceptance.

Executed evidence: `migration_replay/M24/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M25 / Broken migrator is wrapped

A migrator that raises RuntimeError produces a wrapped ValidationError. The failure is preserved rather than turning a partly migrated value into a successful load.

Executed evidence: `migration_replay/M25/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M26 / Successful custom adjacent chain

A disposable custom 1-to-2-to-3 migration chain produces the expected finite value. This is evidence for the extension protocol, not two additional built-in migration edges.

Executed evidence: `migration_replay/M26/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M27 / Adjacent edges and the migrator keyword

A nonadjacent edge is rejected. The accepted keyword is migrator=; the obsolete migrate= spelling raises TypeError. Update the call rather than patching a persisted version tag.

Executed evidence: `migration_replay/M27/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M28 / Preserve originals and reject a damaged envelope

Saving without explicit overwrite refuses replacement and leaves the original bytes unchanged. A separately damaged envelope digest is rejected. Checksums are corruption checks, not authentication.

Executed evidence: `migration_replay/M28/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M29 / Read all seven committed predecessor records

Reconstructs all seven committed predecessor records and compares their expected types, producers and payload digests. These are stored historical fixtures, distinct from the ten records newly written by actual predecessor installations.

Executed evidence: `migration_replay/M29/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

M30 / All three current API contracts

Current stable, beta and research manifests pass their selected strict checks. Those positive structural checks coexist with the separately documented certificate, decoder and resource limitations.

Executed evidence: `migration_replay/M30/result.json`; expectation passed, worker exit 0. Reproduce with `python tools/block44/run_probes.py --output <fresh-directory>`. Each worker has a 90-second timeout; no fixture attempts uncontrolled memory exhaustion or native GPU execution.

L.16 Source mapping, reproducibility and remaining work

Primary sources are compatibility.py, release/upgrade.py, the thirty retained API manifests, the shipped upgrade contract and its seven fixtures, the single portable migration registration, the explicit alias/wrapper implementations, and the deprecation/migration policy documents. Each electronic record includes a source-file SHA-256; AST records retain source ranges and exact text. No external website or later repository state was substituted for the pinned source.

The full source suite passed 1,203 tests. The new reference suite passed 572 tests, including per-file census checks, all historical comparisons, all stable/explicit aliases, selector routes, fixture identities and executed receipts. Thirty probe expectations and five genuine package-upgrade paths passed. The counts overlap. They are neither new theorem counts nor universal semantic equivalence claims.

```
python tools/block44/inventory.py
python tools/block44/upgrade_lab.py --output <fresh-upgrade-directory>
```

```
python tools/block44/run_probes.py --output <fresh-probe-directory>
python tools/block44/run_reference_tests.py
python tools/block44/run_source_tests.py
python tools/block44/generate_manual.py
python tools/block44/build_pdfs.py
python VERIFY_BLOCK44_PACKAGE.py
```

Use a separate working copy for regeneration. The installed-reference tools require the separately installed pinned wheel, not a source checkout on PYTHONPATH. They do not download dependencies. Default evidence directories are immutable replay inputs after review; archive earlier receipts before replacing them. Re-running tools changes evidence hashes and requires a newly reviewed outer archive.

Reference boundaries. This migration and deprecation reference covers the stated alias census and finite upgrade observations for the frozen source. The 901 library files matched that baseline. The observations do not modify package, example or distribution bytes.

The recorded audit did not qualify native Windows/PowerShell, other Python/dependency versions, CUDA, strict MkDocs, fully dependency-isolated installation or final publication. Certificate, portable-reader and resource limitations remain separate from finite upgrade success. The audit included no new Lean proof qualification. Appendix O identifies the final-source execution records.

Appendix M. Glossary and notation index

This is the version-bound terminology reference for **Komorebi Math 1.0.0b4, Repair R2, wheel build 2**. It separates the ordinary mathematical or technical meaning of a term from the behavior of this implementation. A mathematical definition, a stored status flag, a source label and a qualified software artifact answer different questions.

Use this appendix while reading, not as a prerequisite. Search M.4 for an unfamiliar word and M.5 for a symbol. Read the general meaning first, then the "In this library" paragraph, and return to the cited chapter for the full construction or example. M.2 includes alternate search wording when the name you remember differs from the printed term.

If a familiar term seems inconsistent with a nearby formula, check its local meaning before changing the formula. M.3 collects common collisions such as signal frames versus redundant frames, packet projectors versus reconstruction components, and API stability versus a stable core. For a symbol, check the surrounding space, domain and indices as well as its glyph. The same printed symbol can denote different objects in different chapters.

A useful lookup habit. Keep the chapter name with a copied definition or notation card. That context is often enough to distinguish two otherwise identical search results. Follow "See also" links when the distinction concerns the relationship between two objects, such as analysis and synthesis, rather than just an unfamiliar word.

M.1 Scope and reading rules

Reference surface	Included
Reviewed glossary concepts	223
Locally scoped notation senses	66
Distinct displayed notation strings	65
Navigation redirects	28
Explicit terminology collision groups	16
Source chapters/appendices supporting glossary terms	69
Bound Python source files	300
Formula occurrences in the frozen reader source	6411
Finite semantic probe cases	24

The glossary covers the **declared 223-entry concept catalog** and its 66 notation records. It is not an assertion that every ordinary word, every exported method name or every locally bound dummy variable in this 2,000-plus-page manual has a separate semantic definition. Appendices A-D retain exhaustive API/module references. The electronic formula concordance supplies every mathematical span recognized by the delimiter rule below, including occurrences in the historical planning material; it does not infer meanings from glyph frequency.

Each glossary record contains the term, general definition, package-specific interpretation, classical/general sense, explanatory source anchor, related concepts and notation links. Each notation record contains its displayed glyph, spoken form, local definition, explanatory source anchor, domain, collisions and related glossary entry. These implement the retained glossary/notation record shapes at the end of Chapter 88.

Source precedence. Definitions summarize the pinned reader source. Later source-backed Appendix G-H-I-K-L qualifications take precedence over an older unqualified sentence where the two differ. No independent current-library website or later repository revision is substituted. The glossary's frozen Markdown and TeX source remain the authority for its recorded line numbers and hashes. Typeset pagination does not replace those source coordinates.

First anchor. This field means the explanatory chapter for the indexed local sense. It is not a claim about the earliest printed appearance of the same glyph anywhere in the manual. Some displays normalize the source wording into

a convenient expression. Every notation card identifies whether its exact displayed spelling was found in its source chapter. A normalized display is not attributed as a verbatim source formula.

Status separation. General mathematics describes a property under hypotheses. A local implementation decides finite predicates. A certificate stores a producer's report. A portable codec reconstructs that report. Provenance declares a claim class. Release qualification accepts a specified execution profile. None of those operations silently promotes the others into a new proof.

M.2 Fast lookup and ambiguity policy

Alphabetical cards appear in M.4. M.5 is the notation register and M.6 contains executable meaning checks. The electronic lookup tool never chooses one overloaded sense merely because it appears first. An exact collision-group query expands to its distinct concepts. Chapter filtering narrows context; it does not merge meanings.

```
python tools/block45/lookup.py "frame" --kind term
python tools/block45/lookup.py "P_i" --kind notation
python tools/block45/lookup.py "NM-001" --strict-unique
python tools/block45/lookup.py "P_i" --strict-unique
```

The last invocation intentionally exits nonzero because two local records share that glyph. Queries emit JSON. A query with no matches returns an empty result and a nonzero exit status. It does not invent a definition. Search redirects below are navigation aids, not assertions that two concepts or Python objects are identical.

Search wording	Navigate to
adjoint matrix	Adjoint
API stability	API tier
automatic differentiation	Autodiff adapter
basis change	Coordinate transform
Chinese remainder theorem coordinates	CRT coordinates
coefficient gauge freedom	Coefficient gauge
congruence lane	Lane
CRC and SHA-256 checks	Source checksum
CRT	CRT coordinates
cyclic seed	Cyclic vector
deprecation warning	Deprecation
Faà di Bruno formula	Faà di Bruno composition
finite-field Frobenius	Frobenius orbit
formal power series	Formal series
frozen provider	Frozen record
jet	Packet jet
kernel modulo image	Cohomology
linear map realization	Operator realization
normalization weight	Weighted monomial basis
orthogonal packet	Orthogonal projector
packet block	Transfer block
portable envelope	Portable record
power spectral density	Power spectral density
prime-adic valuation	Valuation
PSD	Power spectral density
release acceptance	Qualification
right-hand-side batching	Structured operator
short-time Fourier transform	STFT

M.3 Words whose meanings must stay separate

M.C01. frame

A signal frame is a windowed segment. A redundant frame is an analysis/synthesis presentation.

Compare: Frame, Analysis-synthesis system.

M.C02. frame operator

The package method returns SA; conventional frame notation often uses A* A.

Compare: Frame operator, Analysis-synthesis system.

M.C03. projector

Reconstruction components need not be idempotent; coefficient projectors and physical packet projectors live in different spaces.

Compare: Projector, Reconstruction component, Coefficient projector.

M.C04. exact / valid / proved

Arithmetic/evidence class, stored validity and author-supplied provenance are independent axes.

Compare: Exactness, Validity flag, Claim status.

M.C05. stable

Compatibility tier and surviving candidates in a finite forest are different meanings.

Compare: Stable API, Stable core.

M.C06. Frobenius

The field power map is not a matrix norm.

Compare: Frobenius orbit, Frobenius norm.

M.C07. refinement

Ambient-space packet refinement is not sample-rate conversion.

Compare: Packet refinement, Polyphase refinement, Resampling.

M.C08. support

Boolean transfer support, retained jet addresses and algebraic support/fibers are distinct.

Compare: Transfer graph, Jet support, Fitting fiber.

M.C09. tree

Nonlinear composition trees and signal basis trees have different node semantics.

Compare: Rooted tree, Wavelet packet tree.

M.C10. version

Package, envelope and codec versions advance under separate contracts.

Compare: Codec, Migration, Package upgrade.

M.C11. kernel

A memory kernel, an arithmetic coefficient kernel and the kernel of a linear map are different objects.

Compare: Memory kernel, Digit kernel, Cohomology.

M.C12. gate

Release requirement selection is not proof of an external mathematical completion condition.

Compare: Required gate, Completion gate.

M.C13. backend

Core selection, dependency discovery and an autodiff interface are not interchangeable capabilities.

Compare: Backend, Backend discovery, Autodiff adapter.

M.C14. convolution

Linear, circular and binomially weighted products are different operations on stored data.

Compare: Convolution, Circular convolution, Hurwitz series.

M.C15. residual / defect

A discrepancy is not automatically numerical noise, and a finite obstruction is not automatically a universal no-go theorem.

Compare: Residual, Defect, Obstruction.

M.C16. immutable

Frozen attributes, read-only array buffers and deep immutability are not equivalent.

Compare: Frozen record, Certificate, Snapshot.

M.4 Alphabetical glossary

General meaning includes ordinary technical vocabulary where a term has no independent classical-mathematics sense. The "In this library" paragraph controls implementation interpretation. Source locations support navigation; they are not certificates of the truth of every nearby statement.

Adaptive filter

General meaning. A filter whose coefficients are updated using an observed signal and a declared update rule.

In this library. Finite coefficient updates do not establish universal convergence or learning performance.

Source. Chapter 34 (explanatory anchor `resampling-and-adaptive-filters`); frozen reference-source Markdown lines 29105-29109.

See also. Filter state, Resource budget.

Adjoint

General meaning. The transpose-conjugate map in the global Euclidean/Hermitian convention, or a metric-dependent adjoint when explicitly declared.

In this library. A transpose alone omits conjugation. Frame coefficient and physical adjoints can use different metrics.

Source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 341-347.

See also. Orthogonal projector, Frame operator. **Notation:** NM-007.

Alias

General meaning. A retained name that refers to the same object, or a separately documented delegating compatibility route.

In this library. Identity aliases and wrappers are distinct. A retained spelling is not automatically deprecated.

Source. Appendix L (explanatory anchor `appendix-l-migrations`); frozen reference-source Markdown lines 109674-109680.

See also. Deprecation, Qualified name.

Alpha equivalence

General meaning. Equality of binding structure up to consistent renaming of bound variables.

In this library. It is not arbitrary renaming of free variables and not by itself equality of every numerical expression.

Source. Chapter 50 (explanatory anchor `typed-finite-expression-model`); frozen reference-source Markdown lines 43318-43324.

See also. Lexical binding, Decidable equality. **Notation:** NM-063.

Analysis map

General meaning. A map from physical vectors to their coefficient representation.

In this library. In a redundant presentation the coefficient dimension can exceed the physical dimension.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15519-15525.

See also. Synthesis map, Analysis-synthesis system. **Notation:** NM-028.

Analysis-synthesis system

General meaning. A pair of compatible analysis and synthesis maps forming a left-inverse presentation when verified.

In this library. Bare numerical construction can store a proposal with a failed left-inverse certificate. Construction alone does not establish reconstruction.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15505-15511.

See also. Analysis map, Synthesis map, Frame operator. **Notation:** NM-030.

API tier

General meaning. A compatibility-policy category attached to an interface.

In this library. Stable, beta and research describe the import surface, not mathematical truth or numerical accuracy.

Source. Chapter 7 (explanatory anchor `public-api-tiers`); frozen reference-source Markdown lines 2599-2605.

See also. Exactness, Stable API, Research API.

Appell family

General meaning. A polynomial family satisfying the stated derivative-lowering relation.

In this library. Exact symbolic finite identities do not certify a global zero pattern or convergence of a truncated product.

Source. Chapter 27 (explanatory anchor `cyclic-analytic-systems`); frozen reference-source Markdown lines 24949-24955.

See also. Cyclic analytic packet, Zero certificate.

Approximation budget

General meaning. A declared allowance for a finite approximation or retained model.

In this library. Approximation error, arithmetic roundoff and process memory are different budgets.

Source. Chapter 36A (explanatory anchor `a.-approximation-nonlinear-packet-products-and-smith-charts`); frozen reference-source Markdown lines 31454-31458.

See also. Resource budget, Numerical result.

Arrow

General meaning. A directed operator symbol with a source type and a target type.

In this library. Grammar legality is established before a realization supplies matrices.

Source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3802-3808.

See also. Operator word, Operator grammar.

Assumption

General meaning. A prerequisite on which a stated conclusion depends.

In this library. Checked and unchecked assumptions are separate fields. Declaring a hypothesis does not demonstrate it.

Source. Chapter 5 (explanatory anchor `certificates-and-result-types`); frozen reference-source Markdown lines 1545-1551.

See also. Conditional result, Certificate.

Autodiff adapter

General meaning. A bridge from a supported automatic-differentiation framework into the derivative-provider interface.

In this library. Device, dtype and supported derivative order are explicit. CPU execution does not qualify CUDA.

Source. Chapter 37 (explanatory anchor `derivative-providers-and-automatic-differentiation`); frozen reference-source Markdown lines 31948-31952.

See also. Derivative provider, Backend.

Automatic sequence

General meaning. A sequence evaluated from a finite-state process over radix digits.

In this library. The declared radix and digit direction matter. Fitting a finite sample is not a proof that the whole sequence is automatic.

Source. Chapter 26 (explanatory anchor `exact-sequence-execution`); frozen reference-source Markdown lines 23439-23445.

See also. Cartier automaton, Sequence model.

Backend

General meaning. An implementation of a particular execution or algebra interface.

In this library. Core linear algebra, autodiff adapters and GPU executors are separate interfaces. Discovery does not imply usability or qualification.

Source. Chapter 8 (explanatory anchor `backends-scalar-domains-and-coercion`); frozen reference-source Markdown lines 3185-3189.

See also. Scalar domain, Backend discovery, Autodiff adapter.

Backend discovery

General meaning. A check that a dependency or implementation can be located.

In this library. The discoverable set is broader than names accepted by the core selector. Successful discovery is not a successful device operation.

Source. Chapter J (explanatory anchor `appendix-j-backends-dependencies`); frozen reference-source Markdown lines 106772-106778.

See also. Backend, Qualification.

Basis witness

General meaning. A finite semantic description of a basis used to interpret typed data.

In this library. Names, dimensions and matrix shape alone do not replace the witness that brands polynomial primitives.

Source. Chapter 50 (explanatory anchor `typed-finite-expression-model`); frozen reference-source Markdown lines 43059-43065.

See also. Coordinate system, Typed expression. **Notation:** NM-057.

Bell digit reduction

General meaning. A finite reduction rule relating generalized Bell data to radix-digit structure.

In this library. The certificate checks the stated factorial-power construction and finite coefficient identity, not every Bell-like sequence.

Source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20578-20582.

See also. Digit kernel, Prime-power kernel.

Best basis

General meaning. A basis selected by optimizing a stated cost over the allowed tree choices.

In this library. Best is relative to the finite candidate family and cost, not an absolute optimal representation for every task.

Source. Chapter 35 (explanatory anchor `filter-banks-wavelets-and-packet-trees`); frozen reference-source Markdown lines 30145-30151.

See also. Wavelet packet tree, Pareto frontier.

Beta API

General meaning. A curated interface still governed by beta-stage compatibility rules.

In this library. Beta is not a weaker kind of arithmetic and is not synonymous with a failed result.

Source. Chapter 7 (explanatory anchor `public-api-tiers`); frozen reference-source Markdown lines 2604-2610.

See also. API tier, Stable API.

Canonical dual

General meaning. The dual synthesis associated with an analysis map using the appropriate inverse or pseudoinverse.

In this library. Rank, tolerance and the selected metric govern the construction. Redundant components obtained from it need not be idempotent.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15504-15510.

See also. Analysis-synthesis system, Reconstruction component.

Canonical JSON

General meaning. A deterministic JSON serialization used for the specified content digest.

In this library. Canonical byte equality is a representation property. The payload digest does not authenticate producer metadata or prove the encoded mathematics.

Source. Chapter G (explanatory anchor `appendix-g-portable-schemas`); frozen reference-source Markdown lines 95096-95102.

See also. Source checksum, Portable record.

Carry matrix

General meaning. A finite transition matrix tracking carry states while processing radix digits.

In this library. Digit order and the finite state construction are part of the evaluation contract.

Source. Chapter 23 (explanatory anchor `masks-cartier-operators-and-digit-algebra`); frozen reference-source Markdown lines 19324-19330.

See also. Mahler mask, Automatic sequence.

Cartier automaton

General meaning. A finite state machine obtained by closing the relevant Cartier sections.

In this library. Its existence and state budget are tied to the compiler's finite algebraic model, not an arbitrary sequence prefix.

Source. Chapter 23 (explanatory anchor `masks-cartier-operators-and-digit-algebra`); frozen reference-source Markdown lines 19336-19342.

See also. Cartier operator, Automatic sequence.

Cartier operator

General meaning. A residue-section operator that selects coefficients at indices in a fixed radix class.

In this library. Polynomial, rational-mask and finite-field implementations have distinct finite domains and compiler assumptions.

Source. Chapter 23 (explanatory anchor `masks-cartier-operators-and-digit-algebra`); frozen reference-source Markdown lines 19323-19327.

See also. Section operator, Cartier automaton.

Certificate

General meaning. A record describing a claim and the evidence or diagnostics supplied for it.

In this library. The base require method checks the stored validity flag. It does not re-run a proof, a residual test or a witness-producing algorithm. Specialized certificates have different protocols.

Source. Chapter H (explanatory anchor `appendix-h-certificate-theorem-index`); frozen reference-source Markdown lines 96539-96545.

See also. Validity flag, Finite certificate, Provenance.

Certified rewrite

General meaning. A recorded transformation whose relevant finite expression identity is checked under its assumptions.

In this library. A rewrite's evidence is local to the supported types and primitive semantics, not an unrestricted symbolic law.

Source. Chapter 51 (explanatory anchor `expression-evaluation-and-certification`); frozen reference-source Markdown lines 43678-43684.

See also. Normal form, Certificate.

Choi matrix

General meaning. A matrix representation of a linear quantum map under a specified vectorization convention.

In this library. Positivity, trace conditions and reshape ordering are separate parts of the finite channel contract.

Source. Chapter 54 (explanatory anchor `chapter-54.-circuits-channels-and-open-dynamics`); frozen reference-source Markdown lines 44922-44928.

See also. Quantum channel, Kraus operator.

Circular convolution

General meaning. Convolution with periodic index wrap on a fixed finite length.

In this library. It is not equal to unpadded linear convolution at arbitrary boundaries.

Source. Chapter 33 (explanatory anchor `filtering-and-convolution`); frozen reference-source Markdown lines 28430-28436.

See also. Convolution, Polyphase decomposition.

Claim status

General meaning. A taxonomy such as definition, classical input, conditional theorem or finite certificate.

In this library. This taxonomy is not the ordered Exactness ranking used by expression composition.

Source. Chapter 62 (explanatory anchor `chapter-62.-provenance-registries-and-extensions`); frozen reference-source Markdown lines 46342-46348.

See also. Provenance, Exactness.

Codec

General meaning. A registered tag, version and pair of encoding/decoding procedures for a represented object.

In this library. The package version, envelope schema version and codec version are separate identifiers.

Source. Chapter G (explanatory anchor `appendix-g-portable-schemas`); frozen reference-source Markdown lines 95096-95102.

See also. Migration, Portable record.

Coefficient gauge

General meaning. A change of coefficients that does not change the synthesized physical vector.

In this library. Gauge directions lie in the kernel of synthesis. Different coefficient vectors can therefore encode the same physical vector.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15501-15507.

See also. Coefficient projector, Quotient metric. **Notation:** NM-032.

Coefficient projector

General meaning. The idempotent analysis-after-synthesis map on coefficient space when the left-inverse relation holds.

In this library. It is generally not the full coefficient identity in a redundant presentation.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15500-15506.

See also. Synthesis map, Coefficient gauge. **Notation:** NM-031.

Coercion

General meaning. Conversion into a selected scalar or array representation.

In this library. Symbolic backends do not automatically rationalize a floating input. Converting a float to Fraction preserves its binary value.

Source. Chapter 8 (explanatory anchor `backends-scalar-domains-and-coercion`); frozen reference-source Markdown lines 3185-3189.

See also. Scalar domain, Exact arithmetic.

Coherence

General meaning. A normalized cross-spectral relationship between two finite signals.

In this library. Interpretation depends on cross-spectrum, averaging and zero-power conventions; it is not causality.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 28007-28013.

See also. Welch PSD, Residual.

Cohomology

General meaning. Kernel modulo image for consecutive differentials in a declared complex.

In this library. The finite complex must satisfy the differential-composition condition; dimension counts are not arbitrary obstruction labels.

Source. Chapter 56 (explanatory anchor `chapter-56.-finite-deformation-systems`); frozen reference-source Markdown lines 45204-45210.

See also. Finite spectral sequence, Obstruction.

Common refinement

General meaning. A fine decomposition resolving two compatible decompositions at once.

In this library. The supplied construction requires the relevant packet systems to commute. It is not an arbitrary joint refinement of noncommuting projectors.

Source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6759-6765.

See also. Packet refinement, Projector.

Commuting diagram

General meaning. Two composable routes with the same endpoints and equal induced maps.

In this library. The atlas compares the actual composed matrices and records their difference. Endpoint equality alone is insufficient.

Source. Chapter 15 (explanatory anchor `coordinate-objects`); frozen reference-source Markdown lines 9414-9420.

See also. Coordinate atlas, Residual.

Completion gate

General meaning. A named required condition in the conditional completion model.

In this library. Supplying a gate name as satisfied records an assumption. It does not prove the missing realization or correspondence theorem.

Source. Chapter 58 (explanatory anchor `chapter-58.-finite-image-ramification-and-completion-models`); frozen reference-source Markdown lines 45602-45606.

See also. Conditional result, Required gate.

Conditional result

General meaning. A conclusion whose use depends on assumptions not all established by the computation.

In this library. The wrapper records the dependency on those assumptions. It is not a proof-admission mechanism.

Source. Chapter 5 (explanatory anchor `certificates-and-result-types`); frozen reference-source Markdown lines 1539-1545.

See also. Assumption, Exactness, Completion gate. **Notation:** NM-015.

Conjugate gradients

General meaning. An iterative linear solver whose standard guarantees require the appropriate positive-definite Hermitian setting.

In this library. Local numerical checks and convergence on a fixture do not certify every operator supplied as a callback.

Source. Chapter 30 (explanatory anchor `krylov-precision-compilation-and-scheduling`); frozen reference-source Markdown lines 26688-26694.

See also. Krylov subspace, Residual.

Convolution

General meaning. A sum combining shifted products under a specified finite or periodic indexing rule.

In this library. Signal routines are signal-first. Full, same, valid and circular modes have different lengths and boundary meanings.

Source. Chapter 33 (explanatory anchor `filtering-and-convolution`); frozen reference-source Markdown lines 28426-28430.

See also. Circular convolution, Hurwitz series.

Coordinate atlas

General meaning. A finite graph of named coordinate systems and registered transformations.

In this library. Route resolution follows registered edges. Commutativity means equality of composed matrices, not merely matching endpoints.

Source. Chapter 15 (explanatory anchor `coordinate-objects`); frozen reference-source Markdown lines 9154-9160.

See also. Coordinate transform, Commuting diagram.

Coordinate covector

General meaning. A linear functional expressed as a row of coefficients dual to a coordinate basis.

In this library. Under coordinate change the covector must transform contragrediently to preserve its pairing with vectors.

Source. Chapter 49 (explanatory anchor `integral-identities-and-coordinate-covectors`); frozen reference-source Markdown lines 42488-42492.

See also. Coordinate vector, Integral identity.

Coordinate system

General meaning. A named finite vector-space presentation with a dimension and basis convention.

In this library. Coordinate-system names and dimensions participate in typed transport. Equal array shapes do not make different named systems identical.

Source. Chapter 15 (explanatory anchor `coordinate-objects`); frozen reference-source Markdown lines 9171-9177.

See also. Coordinate transform, Basis witness.

Coordinate transform

General meaning. A linear change from source coordinates to target coordinates.

In this library. Exact transforms use rational matrices. Composition applies the source transform first and multiplies the following matrix on the left.

Source. Chapter 16 (explanatory anchor `exact-and-numerical-coordinate-transforms`); frozen reference-source Markdown lines 9775-9781.

See also. Coordinate system, Coordinate atlas. **Notation:** NM-011, NM-012.

Coordinate vector

General meaning. Coefficients interpreted in a specified coordinate system.

In this library. The low-level Vector alias is a raw tuple of Fraction values; higher-level objects supply system context. The same tuple in another basis can denote a different vector.

Source. Chapter 15 (explanatory anchor `coordinate-objects`); frozen reference-source Markdown lines 9155-9161.

See also. Coordinate system, Coordinate covector.

Correction

General meaning. A finite adjustment intended to reduce a defect under a specified solver or update rule.

In this library. Successful local correction is not a general convergence or global existence theorem.

Source. Chapter 41 (explanatory anchor `correction-and-elimination`); frozen reference-source Markdown lines 35474-35478.

See also. Defect, Elimination.

Coverage contract

General meaning. A declared inventory and acceptance rule for what a reference promises to document.

In this library. Counts describe named surfaces, not an independent proof of every implementation or a platform qualification.

Source. Chapter 0 (explanatory anchor `coverage-contract`); frozen reference-source Markdown lines 22-26.

See also. Symbol card, Source checksum. **Notation:** NM-061, NM-062.

CRT coordinates

General meaning. Coordinates using residues in a Chinese-remainder decomposition.

In this library. Invertible reconstruction requires the stated coprimality hypotheses. It is not simply digit concatenation.

Source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8022-8028.

See also. Residue coordinate, Mixed-radix address.

Cyclic analytic packet

General meaning. A residue-class decomposition used in the finite cyclic analytic constructions.

In this library. Exact coefficient identities coexist with numerical or conditional zero and product diagnostics.

Source. Chapter 27 (explanatory anchor `cyclic-analytic-systems`); frozen reference-source Markdown lines 24948-24954.

See also. Appell family, Zero certificate.

Cyclic vector

General meaning. A vector whose algebra orbit spans the whole representation.

In this library. Existence and a supplied vector's generation certificate are separate claims.

Source. Chapter 10 (explanatory anchor `operator-algebras-and-seed-systems`); frozen reference-source Markdown lines 4853-4859.

See also. Seed system, Orbit hull.

Cyclotomic coboundary

General meaning. A mask represented as a ratio induced by a cyclotomic factor construction under scaling.

In this library. The finite procedure returns exponents or obstruction orbits. It is not a generic analytic convergence certificate.

Source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20591-20597.

See also. Mahler mask, Obstruction.

Decidable equality

General meaning. Equality determined by a terminating procedure in a specified finite language and domain.

In this library. The expression normalizer's scope is not all mathematical functions, arbitrary callbacks or infinite analytic objects.

Source. Chapter 51 (explanatory anchor `expression-evaluation-and-certification`); frozen reference-source Markdown lines 43544-43550.

See also. Normal form, Alpha equivalence.

Defect

General meaning. A computed discrepancy from a declared compatibility, invariance or lifting identity.

In this library. It can be an exact obstruction signal or a numerical residual. Its class does not automatically diagnose roundoff.

Source. Chapter 40 (explanatory anchor `defects-obstruction-lifting-and-holonomy`); frozen reference-source Markdown lines 34282-34286.

See also. Obstruction, Refinement defect.

Deprecation

General meaning. A compatibility notice indicating that a route should be replaced under a declared policy.

In this library. The generic decorator records metadata and emits a warning. Its remove_in field does not automatically disable a callable at a version boundary.

Source. Appendix L (explanatory anchor `appendix-l-migrations`); frozen reference-source Markdown lines 109991-109997.

See also. Alias, Package upgrade.

Derivative provider

General meaning. An interface supplying finite-order derivative evaluations with declared dimensions and evidence class.

In this library. A callback's declared multilinearity or smoothness is not proved solely by the interface.

Source. Chapter 37 (explanatory anchor `derivative-providers-and-automatic-differentiation`); frozen reference-source Markdown lines 31979-31985.

See also. Autodiff adapter, Packet jet. **Notation:** NM-046.

Digit kernel

General meaning. A local coefficient rule combined across radix digits.

In this library. Lucas and no-borrow behavior are model-dependent and must not be inferred for an arbitrary normalized kernel.

Source. Chapter 23 (explanatory anchor `masks-cartier-operators-and-digit-algebra`); frozen reference-source Markdown lines 19326-19332.

See also. Carry matrix, Kummer valuation.

Document model

General meaning. A typed representation of metadata and an ordered buffer of mathematical document blocks.

In this library. Renderers share this semantic source while producing different text formats. Rendered bytes are not the portable reconstruction format.

Source. Chapter 59 (explanatory anchor `chapter-59.-mathematical-document-model`); frozen reference-source Markdown lines 45895-45901.

See also. Renderer, Portable record. **Notation:** NM-059.

Elimination

General meaning. Removal of selected variables or sectors through a stated algebraic procedure.

In this library. Inverse and rank assumptions control validity, and eliminated dynamics can retain memory.

Source. Chapter 41 (explanatory anchor `correction-and-elimination`); frozen reference-source Markdown lines 35474-35478.

See also. Feshbach reduction, Correction.

Euler coordinates

General meaning. A finite coordinate system for the specified odd-prime or dyadic Euler arithmetic model.

In this library. The applicable prime, window and truncation conditions are part of the reconstruction claim.

Source. Chapter 25 (explanatory anchor `local-arithmetic-models`); frozen reference-source Markdown lines 21820-21826.

See also. Residue coordinate, Truncation.

Exact arithmetic

General meaning. Arithmetic in a declared exact domain rather than tolerance-based floating comparison.

In this library. Rational operations can be exact while a finite prefix, caller hypothesis or certificate producer still limits the conclusion.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16943-16949.

See also. Scalar domain, Formal series, Exactness. **Notation:** NM-002.

Exactness

General meaning. The kind of evidence or arithmetic attributed to a result.

In this library. Exactness is distinct from certificate validity and provenance status. An enum value does not independently validate a computation.

Source. Chapter 5 (explanatory anchor `certificates-and-result-types`); frozen reference-source Markdown lines 1547-1553.

See also. Certificate, Numerical result, Conditional result. **Notation:** NM-013.

Execution plan

General meaning. A finite representation of selected work, addresses and execution options.

In this library. Plan integrity and plan resource estimates are separate from a successful execution or device qualification.

Source. Chapter 43 (explanatory anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`); frozen reference-source Markdown lines 37424-37430.

See also. Resource budget, Packet IR.

Faà di Bruno composition

General meaning. A derivative-composition formula organized by partitions of input directions.

In this library. The finite formula assumes the relevant derivative-provider contracts. Partitions here differ from integer partitions or signal packet trees.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32528-32532.

See also. Set partition, Derivative provider.

Feature registry

General meaning. An index of implemented, conditional or planned domain capabilities.

In this library. A registered name and its status do not supply a proof or guarantee that every optional backend is installed.

Source. Chapter 62 (explanatory anchor `chapter-62.-provenance-registries-and-extensions`); frozen reference-source Markdown lines 46334-46340.

See also. Planned feature, Provenance.

Feshbach reduction

General meaning. Elimination of a complementary sector with an effective operator depending on a resolvent or memory term.

In this library. The required hidden-sector inverse must exist. Reduced evolution is not generally local or Markovian.

Source. Chapter 46 (explanatory anchor `feshbach-reduction-memory-and-survival`); frozen reference-source Markdown lines 40656-40660.

See also. Memory kernel, Elimination.

Filter bank

General meaning. A family of analysis/synthesis filters with explicit sampling and reconstruction structure.

In this library. Perfect reconstruction is a property to check under the selected finite boundary and phase conventions.

Source. Chapter 35 (explanatory anchor `filter-banks-wavelets-and-packet-trees`); frozen reference-source Markdown lines 29632-29636.

See also. Wavelet packet tree, Polyphase decomposition.

Filter state

General meaning. Retained information needed to continue a streaming or recursive filter.

In this library. Restarting with an empty state can change boundary outputs even when filter coefficients are identical.

Source. Chapter 33 (explanatory anchor `filtering-and-convolution`); frozen reference-source Markdown lines 28602-28608.

See also. Convolution, Adaptive filter.

Filtered lift

General meaning. A compatible extension through represented filtration levels.

In this library. Finite level compatibility does not automatically produce an infinite lift.

Source. Chapter 42 (explanatory anchor `filtered-lifting-and-finite-spectral-sequences`); frozen reference-source Markdown lines 36452-36456.

See also. Obstruction, Finite spectral sequence.

Finite certificate

General meaning. Evidence for a specified finite calculation under stated assumptions.

In this library. Its scope is the checked dimensions, inputs, domains and predicates. It is not automatically an infinite theorem or a Lean proof.

Source. Chapter 5 (explanatory anchor `certificates-and-result-types`); frozen reference-source Markdown lines 1553-1559.

See also. Certificate, Exactness, Assumption.

Finite field

General meaning. A field with finitely many elements represented through a prime field and an extension construction.

In this library. The supplied modulus polynomial, coefficient ordering and irreducibility conditions govern valid arithmetic.

Source. Chapter 57 (explanatory anchor `chapter-57.-local-finite-langlands-packets`); frozen reference-source Markdown lines 45436-45442.

See also. Prime field, Frobenius orbit. **Notation:** NM-056.

Finite Heisenberg model

General meaning. A finite algebraic representation capturing the declared Heisenberg commutation structure.

In this library. The model supplies finite matrices and diagnostics, not the local Langlands correspondence.

Source. Chapter 57 (explanatory anchor `chapter-57.-local-finite-langlands-packets`); frozen reference-source Markdown lines 45430-45436.

See also. Symmetry packet, Completion gate.

Finite lift forest

General meaning. Finite candidate levels connected by explicit adjacent reduction maps.

In this library. A surviving branch is compatible through represented levels only. It is not an automatically proved infinite inverse-limit branch.

Source. Chapter 56 (explanatory anchor `chapter-56.-finite-deformation-systems`); frozen reference-source Markdown lines 45209-45215.

See also. Stable core, Filtered lift.

Finite measure

General meaning. A measure model explicitly represented on a finite domain or by specified finite data.

In this library. Exact integration claims depend on the measure normalization and integrand representation.

Source. Chapter 47 (explanatory anchor `measures-and-exact-polynomials`); frozen reference-source Markdown lines 41459-41463.

See also. Integration provider, Moment.

Finite spectral sequence

General meaning. Page-wise algebraic bookkeeping for a represented finite filtered complex.

In this library. Finite computed pages and differentials are not a claim of unbounded convergence beyond the supplied model.

Source. Chapter 42 (explanatory anchor `filtered-lifting-and-finite-spectral-sequences`); frozen reference-source Markdown lines 36452-36456.

See also. Cohomology, Filtered lift.

Fitting fiber

General meaning. A finite support/fiber diagnostic constructed from the declared presentation data.

In this library. It is algebraic support information, not automatically a Hilbert-space spectral projector.

Source. Chapter 56 (explanatory anchor `chapter-56.-finite-deformation-systems`); frozen reference-source Markdown lines 45306-45312.

See also. Cohomology, Symmetry packet.

Formal series

General meaning. A coefficient sequence treated algebraically without an analytic convergence requirement.

In this library. The package stores a finite prefix in a declared scalar domain and normalized basis. A prefix is not an infinite lazy series.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16908-16914.

See also. Weighted monomial basis, Truncation.

Frame

General meaning. A finite windowed segment in the signal-framing sense.

In this library. This is not the redundant linear-algebra meaning of a frame. Arrays place frame number and within-frame sample on separate axes.

Source. Chapter 31 (explanatory anchor `signal-conventions-windows-and-framing`); frozen reference-source Markdown lines 27208-27214.

See also. Analysis-synthesis system, Window, STFT.

Frame operator

General meaning. In conventional frame notation the analysis Gram action on physical space is often written as the adjoint-analysis product.

In this library. The frozen package method instead returns synthesis times analysis, the physical reconstruction operator. Do not replace it blindly by the conventional expression.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15580-15586.

See also. Analysis-synthesis system, Adjoint.

Frobenius norm

General meaning. The square root of the sum of squared absolute matrix entries.

In this library. It is one specific residual norm, distinct from an arithmetic Frobenius map or an operator spectral norm.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15615-15621.

See also. Frobenius orbit, Residual. **Notation:** NM-033.

Frobenius orbit

General meaning. An orbit under the characteristic-prime power map in a finite-field model.

In this library. Frobenius here is an arithmetic map, not the Frobenius matrix norm.

Source. Chapter 57 (explanatory anchor `chapter-57.-local-finite-langlands-packets`); frozen reference-source Markdown lines 45429-45435.

See also. Finite field, Frobenius norm.

Frozen record

General meaning. A finite data capture replacing an executable or evolving source with a portable representation.

In this library. Freezing removes reliance on a live provider where supported. Frozen dataclass syntax alone does not guarantee deep immutability of nested dictionaries.

Source. Chapter 22 (explanatory anchor `normalized-generating-functions`); frozen reference-source Markdown lines 17860-17866.

See also. Snapshot, Portable record.

Fundamental matrix

General meaning. A matrix-valued evolution operator for a declared finite linear differential system.

In this library. Numerical discretization, exact model identities and user-supplied generator assumptions remain distinct.

Source. Chapter 27 (explanatory anchor `cyclic-analytic-systems`); frozen reference-source Markdown lines 25201-25207.

See also. Matrix dynamics, Backend.

Generated operator algebra

General meaning. The unital matrix algebra generated by a finite family of square operators.

In this library. The implementation builds a finite span. Numerical independence depends on tolerance, whereas the exact backend uses exact decisions.

Source. Chapter 10 (explanatory anchor `operator-algebras-and-seed-systems`); frozen reference-source Markdown lines 4724-4730.

See also. Seed system, Orbit hull. **Notation:** NM-022.

Generating provider

General meaning. A rule or finite specification supplying coefficients for a generating function.

In this library. A mathematical infinite definition is executed only through a requested finite prefix. Opaque callbacks are not automatically portable.

Source. Chapter 22 (explanatory anchor `normalized-generating-functions`); frozen reference-source Markdown lines 17857-17863.

See also. Formal series, Frozen record.

Heuristic

General meaning. A discovery method or estimate without the complete guarantee of the stronger claimed property.

In this library. A good finite fit or small residual alone does not promote the label to an exact or global theorem.

Source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 240-246.

See also. Planned feature, Finite certificate. **Notation:** NM-016.

Holonomic recurrence

General meaning. A linear recurrence with polynomial coefficients in the index.

In this library. A vanishing leading coefficient can block forward evaluation at an index. Initial data and singular steps must be inspected.

Source. Chapter 26 (explanatory anchor `exact-sequence-execution`); frozen reference-source Markdown lines 23466-23472.

See also. Linear recurrence, Sequence model.

Holonomy

General meaning. The net transport obtained around a closed route.

In this library. Trivial endpoints alone do not make the composed transport the identity. Finite holonomy diagnostics require the actual route maps.

Source. Chapter 40 (explanatory anchor `defects-obstruction-lifting-and-holonomy`); frozen reference-source Markdown lines 34282-34286.

See also. Coordinate atlas, Commuting diagram.

Hurwitz series

General meaning. A coefficient algebra using the binomially weighted product associated with exponential normalization.

In this library. Finite truncation and scalar-domain assumptions remain explicit. Its product is not ordinary unweighted convolution on stored coefficients.

Source. Chapter 25 (explanatory anchor `local-arithmetic-models`); frozen reference-source Markdown lines 21845-21851.

See also. Normalized coefficient, Convolution. **Notation:** NM-037.

Integral identity

General meaning. An equality between specified integral or functional expressions.

In this library. The certificate records the finite basis and measure conditions actually checked, not an unrestricted analytic identity.

Source. Chapter 49 (explanatory anchor `integral-identities-and-coordinate-covectors`); frozen reference-source Markdown lines 42489-42495.

See also. Coordinate covector, Integration provider.

Integration provider

General meaning. An interface supplying an integral and its stated evidence guarantee.

In this library. Exact finite polynomial integration, numerical quadrature and conditional user providers are different contracts.

Source. Chapter 48 (explanatory anchor `integration-providers-and-quadrature`); frozen reference-source Markdown lines 41957-41961.

See also. Quadrature, Coordinate covector.

Inverse STFT

General meaning. Reconstruction from compatible time-frequency frames.

In this library. Inversion relies on the recorded framing/window/boundary conventions and overlap support, not just matching array dimensions.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27660-27666.

See also. STFT, Overlap-add.

Jet address

General meaning. One output label together with an ordered tuple of input packet labels.

In this library. Derivative order is the input tuple length. Output-major and input-lexicographic ordering are part of the record contract.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32540-32546.

See also. Packet jet, Multi-index. **Notation:** NM-047, NM-048.

Jet support

General meaning. A selection or diagnostic of packet-jet addresses retained as active.

In this library. Numerical support and a complete exact address enumeration have different evidence. Omitting a small block is not exact vanishing.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32540-32546.

See also. Packet jet, Transfer graph.

Kato transport

General meaning. Transport adapted to moving projector sectors.

In this library. The finite implementation uses the specified generator and numerical or exact path assumptions, not a universal adiabatic theorem.

Source. Chapter 54 (explanatory anchor `chapter-54.-circuits-channels-and-open-dynamics`); frozen reference-source Markdown lines 44832-44838.

See also. Smooth packet transport, Orthogonal projector.

Knill-Laflamme condition

General meaning. The condition that each compressed error-product operator acts as a scalar on the code subspace.

In this library. Numerical satisfaction is relative to the declared tolerance and supplied error set. It is not protection against unspecified errors.

Source. Chapter 55 (explanatory anchor `chapter-55.-error-correction-and-effective-dynamics`); frozen reference-source Markdown lines 45083-45089.

See also. Quantum code, Orthogonal projector.

Kraus operator

General meaning. One operator in an operator-sum representation of a quantum map.

In this library. A supplied error family or arbitrary operator list need not already define a trace-preserving channel.

Source. Chapter 54 (explanatory anchor `chapter-54.-circuits-channels-and-open-dynamics`); frozen reference-source Markdown lines 44911-44917.

See also. Quantum channel, Quantum code.

Kronecker product

General meaning. The matrix representation of a tensor product in a specified factor ordering.

In this library. Apply cost and storage depend on the structured path versus dense materialization.

Source. Chapter 29 (explanatory anchor `structured-and-low-rank-operators`); frozen reference-source Markdown lines 26422-26428.

See also. Tensor coordinate transport, Structured operator.

Krylov subspace

General meaning. The span of a starting vector and its successive images under an operator.

In this library. Finite callable probes do not prove global linearity, Hermitian symmetry or positive definiteness.

Source. Chapter 30 (explanatory anchor `krylov-precision-compilation-and-scheduling`); frozen reference-source Markdown lines 26697-26703.

See also. Conjugate gradients, Seed system. **Notation:** NM-039.

Kummer valuation

General meaning. A prime-adic valuation of a combinatorial coefficient expressed through carry or digit data.

In this library. Valuation and unit part are separate. The implemented branch and modulus determine the recovered residue.

Source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20579-20585.

See also. Unit part, Prime-power kernel.

Lane

General meaning. A residue-indexed channel in an arithmetic or coefficient decomposition.

In this library. It is a mathematical indexing convention here, not a CPU SIMD lane or an independently learned latent unit.

Source. Chapter 23 (explanatory anchor `masks-cartier-operators-and-digit-algebra`); frozen reference-source Markdown lines 19325-19331.

See also. Residue coordinate, Polyphase decomposition.

Lattice quotient

General meaning. Cosets of an integer lattice modulo a declared sublattice.

In this library. Finite address counts depend on the lattice index and the nonsingularity hypotheses used by the constructor.

Source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8019-8023.

See also. Smith coordinates, Residue coordinate.

Leakage

General meaning. Transfer from a chosen sector into its complement.

In this library. The norm and packet selection define the diagnostic. Small finite leakage is not exact invariant-subspace closure.

Source. Chapter 53 (explanatory anchor `chapter-53.-finite-quantum-foundations`); frozen reference-source Markdown lines 44601-44607.

See also. Survival operator, Transfer block.

Lexical binding

General meaning. Association of a variable occurrence with its enclosing binder.

In this library. Binding scope matters to evaluation and equality; matching displayed names is insufficient.

Source. Chapter 50 (explanatory anchor `typed-finite-expression-model`); frozen reference-source Markdown lines 43257-43263.

See also. Alpha equivalence, Typed expression.

Lindblad generator

General meaning. A generator of the stated finite open-system evolution with Hamiltonian and dissipative terms.

In this library. A finite matrix construction does not assert all infinite-dimensional semigroup hypotheses.

Source. Chapter 54 (explanatory anchor `chapter-54.-circuits-channels-and-open-dynamics`); frozen reference-source Markdown lines 44832-44838.

See also. Matrix dynamics, Quantum channel.

Linear recurrence

General meaning. A relation determining future terms from a finite set of predecessors.

In this library. Declared constant recurrences and polynomial-coefficient holonomic recurrences have different execution and singularity conditions.

Source. Chapter 26 (explanatory anchor `exact-sequence-execution`); frozen reference-source Markdown lines 23432-23438.

See also. Holonomic recurrence, Sequence model.

Low-rank factorization

General meaning. Representation of a matrix as a product through a lower-dimensional intermediate space.

In this library. Numerical recompression uses a declared approximation criterion and is not an exact rank theorem for noisy data.

Source. Chapter 29 (explanatory anchor `structured-and-low-rank-operators`); frozen reference-source Markdown lines 26372-26376.

See also. Structured operator, Residual.

Mahler mask

General meaning. A finite mask defining a radix scale equation for a generating function.

In this library. Coefficients are interpreted through that scale equation, not automatically through an ordinary rational function with the same finite data.

Source. Chapter 23 (explanatory anchor `masks-cartier-operators-and-digit-algebra`); frozen reference-source Markdown lines 19324-19330.

See also. Carry matrix, Cartier operator.

Matrix dynamics

General meaning. Finite evolution specified by a matrix generator or sequence of matrices.

In this library. Semigroup, Markov, Bayesian and related finite models have different assumptions and backend paths.

Source. Chapter 45 (explanatory anchor `matrix-dynamics`); frozen reference-source Markdown lines 39356-39360.

See also. Fundamental matrix, Feshbach reduction. **Notation:** NM-052.

Matrix-chain plan

General meaning. A parenthesization chosen to optimize a stated dense matrix-composition cost.

In this library. Equal mathematical products can have different finite arithmetic costs. The plan digest is distinct from the expression's semantic digest.

Source. Chapter 52 (explanatory anchor `expression-planning-and-persistence`); frozen reference-source Markdown lines 44004-44010.

See also. Execution plan, Canonical JSON.

Memory estimate

General meaning. A model of storage for a specified representation.

In this library. Array nbytes omits referenced object payloads and some temporaries. Traced allocations are not total resident or GPU memory.

Source. Chapter K (explanatory anchor `appendix-k-resource-budgets`); frozen reference-source Markdown lines 108451-108457.

See also. Resource budget, Exact arithmetic. **Notation:** NM-066.

Memory kernel

General meaning. A kernel carrying feedback from eliminated history into the retained sector.

In this library. Nonlocal memory is an expected structural outcome, not a solver error to relabel as Markovian closure.

Source. Chapter 46 (explanatory anchor `feshbach-reduction-memory-and-survival`); frozen reference-source Markdown lines 40656-40660.

See also. Feshbach reduction, Survival operator.

Migration

General meaning. A declared transformation between adjacent versions of a serialized representation.

In this library. The built-in snapshot edge is one concrete migration. No generic downgrade or arbitrary future-version support is implied.

Source. Appendix L (explanatory anchor `appendix-l-migrations`); frozen reference-source Markdown lines 110024-110030.

See also. Codec, Package upgrade.

Mixed-radix address

General meaning. A positional address whose digit places have specified possibly different radices.

In this library. Radix order and residue conventions are part of the coordinate contract. It is not interchangeable with CRT reconstruction.

Source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8021-8027.

See also. CRT coordinates, Lane. **Notation:** NM-027.

Moment

General meaning. An integral of a declared basis monomial or polynomial against a specified measure.

In this library. A finite list of moments is not automatically a uniquely determined measure or all-order reconstruction.

Source. Chapter 47 (explanatory anchor `measures-and-exact-polynomials`); frozen reference-source Markdown lines 41461-41467.

See also. Finite measure, Quadrature.

Monoid series

General meaning. A finite coefficient object whose multiplication follows the declared index monoid.

In this library. Changing the monoid changes the convolution law. It is not merely another name for ordinary power-series multiplication.

Source. Chapter 22 (explanatory anchor `normalized-generating-functions`); frozen reference-source Markdown lines 17858-17864.

See also. Formal series, Convolution.

Multi-index

General meaning. A finite tuple indexing several positions, directions or powers.

In this library. Ordered jet packet labels are not automatically commuting polynomial exponents. Read the local address interpretation.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32546-32552.

See also. Jet address, Set partition.

Normal form

General meaning. A canonical evaluated representation used to compare the supported finite expressions.

In this library. Closed value terms normalize to exact vectors and map terms to exact matrices under the declared type semantics.

Source. Chapter 51 (explanatory anchor `expression-evaluation-and-certification`); frozen reference-source Markdown lines 43518-43524.

See also. Decidable equality, Typed expression. **Notation:** NM-058.

Normalized coefficient

General meaning. A coefficient measured relative to a chosen normalized basis.

In this library. With basis z^n/gamma_n the ordinary coefficient is a_n/gamma_n. Changing normalization changes stored values, not just display.

Source. Chapter 22 (explanatory anchor `normalized-generating-functions`); frozen reference-source Markdown lines 17856-17862.

See also. Weighted monomial basis, Hurwitz series. **Notation:** NM-036.

Numerical result

General meaning. A result obtained through floating computation and interpreted using a declared error model.

In this library. Residuals and tolerances must be read explicitly. Decreasing a tolerance does not convert floating work into exact arithmetic.

Source. Chapter 5 (explanatory anchor `certificates-and-result-types`); frozen reference-source Markdown lines 1554-1560.

See also. Residual, Tolerance, Exact arithmetic. **Notation:** NM-003, NM-014.

Observable

General meaning. An operator representing a measured quantity in a specified quantum model.

In this library. The foundation uses finite matrices with explicit Hermiticity and algebra hypotheses. It does not infer an infinite physical theory.

Source. Chapter 53 (explanatory anchor `chapter-53.-finite-quantum-foundations`); frozen reference-source Markdown lines 44599-44605.

See also. Quantum channel, Symmetry packet. **Notation:** NM-053.

Obstruction

General meaning. A quantity or class preventing a proposed lift or compatibility condition from being satisfied.

In this library. Vanishing of the checked finite obstruction is only as strong as the model's stated sufficiency assumptions.

Source. Chapter 40 (explanatory anchor `defects-obstruction-lifting-and-holonomy`); frozen reference-source Markdown lines 34282-34286.

See also. Defect, Filtered lift.

Operator conjugation

General meaning. Transport of an operator into another coordinate presentation.

In this library. For one change of basis the transformed matrix uses the change and its inverse in the documented order. Source and target changes may differ.

Source. Chapter 19 (explanatory anchor `spectral-packet-tensor-and-operator-transport`); frozen reference-source Markdown lines 14173-14179.

See also. Coordinate transform, Transfer block.

Operator grammar

General meaning. A typed directed multigraph with declared linear relations among parallel paths.

In this library. It describes allowed syntax. A separate realization determines whether the relations hold for actual matrices.

Source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3823-3829.

See also. Operator realization, Operator relation. **Notation:** NM-021.

Operator realization

General meaning. Assignment of finite spaces and matrices to a typed grammar.

In this library. Relation residuals are checked in the chosen backend. A declaration and a verified realization are different objects.

Source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3792-3798.

See also. Operator grammar, Backend.

Operator relation

General meaning. A finite linear combination of parallel paths declared equal to zero.

In this library. Equal endpoints are a type requirement, not evidence that a chosen realization satisfies the relation.

Source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3825-3831.

See also. Operator word, Residual.

Operator word

General meaning. A composable finite path of operator symbols.

In this library. Its written/execution order must be distinguished from the right-to-left order in the resulting matrix product.

Source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3826-3832.

See also. Arrow, Operator relation, Operator realization. **Notation:** NM-065.

Orbit hull

General meaning. The span of vectors reachable by applying the algebra to supplied seeds.

In this library. Its dimension is bounded by the ambient finite vector-space dimension. Numerical rank is tolerance-dependent.

Source. Chapter 10 (explanatory anchor `operator-algebras-and-seed-systems`); frozen reference-source Markdown lines 4728-4734.

See also. Seed system, Generated operator algebra.

Orthogonal projector

General meaning. An idempotent that is also self-adjoint for the stated inner product.

In this library. Algebraic annihilation of distinct packets is not by itself Hilbert orthogonality. The pinned hilbert check has a validation-bypass boundary documented in H.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32538-32544.

See also. Projector, Adjoint, Packet system.

Overlap-add

General meaning. Reconstruction by adding shifted, weighted finite frames.

In this library. Covered samples and the analysis/synthesis normalization must satisfy the stated nonzero overlap conditions.

Source. Chapter 31 (explanatory anchor `signal-conventions-windows-and-framing`); frozen reference-source Markdown lines 27219-27225.

See also. Window, STFT.

Package upgrade

General meaning. Replacement of an installed distribution with a later tested artifact.

In this library. Passing finite predecessor fixtures does not establish every historical behavior, dependency combination or downgrade path.

Source. Appendix L (explanatory anchor `appendix-l-migrations`); frozen reference-source Markdown lines 109676-109682.

See also. Migration, Qualification.

Packet coordinates

General meaning. A vector represented by its projected packet components.

In this library. General packet components can remain full ambient vectors. They are not automatically compressed scalar coefficients.

Source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5651-5657.

See also. Packet system, Coordinate system.

Packet IR

General meaning. An intermediate representation of a finite operator through addressed blocks.

In this library. Layouts, support and execution schedules are data for the finite computation, not proofs of a universal complexity advantage.

Source. Chapter 28 (explanatory anchor `packet-intermediate-representation`); frozen reference-source Markdown lines 26037-26043.

See also. Packet layout, Structured operator.

Packet jet

General meaning. An output-projected multilinear derivative with each input direction projected into a named packet.

In this library. Finite jet reconstruction requires complete packet decompositions and the provider hypotheses. It does not establish convergence of an infinite Taylor series.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32540-32546.

See also. Jet address, Jet support, Taylor truncation. **Notation:** NM-049.

Packet layout

General meaning. A finite division of coordinates into named contiguous blocks with explicit sizes.

In this library. It is an array layout, not an arbitrary family of ambient projectors. Target/source block order remains explicit.

Source. Chapter 28 (explanatory anchor `packet-intermediate-representation`); frozen reference-source Markdown lines 26051-26057.

See also. Packet IR, Packet system.

Packet operator

General meaning. An operator represented through all compatible packet transfer blocks.

In this library. Reconstruction and composition use the complete source and target decompositions under their checked hypotheses.

Source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5653-5659.

See also. Transfer block, Packet coordinates.

Packet refinement

General meaning. A fine packet system with a parent map whose children sum to each coarse packet.

In this library. Both levels act on the same ambient space. Refinement is not resampling or an increase in vector dimension.

Source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6756-6762.

See also. Refinement tower, Common refinement. **Notation:** NM-024, NM-025.

Packet system

General meaning. A finite complete family of pairwise-annihilating idempotent maps.

In this library. General packets need not be self-adjoint. Hilbert orthogonality is a separate condition, and bypassing construction validation leaves prerequisites unchecked.

Source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5654-5660.

See also. Projector, Orthogonal projector, Transfer block. **Notation:** NM-009.

Pareto frontier

General meaning. Nondominated choices under several explicit optimization criteria.

In this library. Nondominance is relative to the candidates, costs and constraints actually enumerated.

Source. Chapter 30 (explanatory anchor `krylov-precision-compilation-and-scheduling`); frozen reference-source Markdown lines 26961-26967.

See also. Precision allocation, Execution plan.

Periodogram

General meaning. A finite spectral estimator obtained from a transformed signal and normalization.

In this library. Spectrum versus density scaling and one-sided doubling are explicit choices.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27890-27896.

See also. Welch PSD, Sample rate.

Planned feature

General meaning. A named but unimplemented or reserved capability.

In this library. Registry availability and a documented name must not be mistaken for an executable implementation.

Source. Chapter 6 (explanatory anchor `errors-assumptions-and-resource-guards`); frozen reference-source Markdown lines 2150-2156.

See also. Feature registry, Heuristic. **Notation:** NM-017.

Polynomial basis

General meaning. A specified ordered basis for a finite polynomial space.

In this library. Coefficients are meaningful only with that basis and truncation degree. Classical family parameters form part of the contract.

Source. Chapter 17 (explanatory anchor `polynomial-and-classical-coordinate-families`); frozen reference-source Markdown lines 10819-10823.

See also. Normalized coefficient, Basis witness.

Polyphase decomposition

General meaning. Separation of a finite sequence into residue-indexed phases.

In this library. Phase ordering, lengths and synthesis conventions are explicit. Exact reconstruction of phases does not prove an infinite filter identity.

Source. Chapter 14 (explanatory anchor `polyphase-systems-and-refinement`); frozen reference-source Markdown lines 8703-8707.

See also. Lane, Polyphase refinement.

Polyphase refinement

General meaning. Refinement of residue phases into finer phases with a declared reconstruction map.

In this library. This arithmetic address refinement is distinct from changing a signal's sample rate.

Source. Chapter 14 (explanatory anchor `polyphase-systems-and-refinement`); frozen reference-source Markdown lines 8805-8811.

See also. Polyphase decomposition, Resampling.

Portable record

General meaning. A finite data representation decoded through the admitted structural grammar and registered codecs.

In this library. Decoding reconstructs stored information, not an independently verified mathematical witness. Decoder strictness varies by codec.

Source. Chapter G (explanatory anchor `appendix-g-portable-schemas`); frozen reference-source Markdown lines 95098-95104.

See also. Codec, Certificate, Canonical JSON.

Power spectral density

General meaning. A spectral power representation normalized per unit of frequency.

In this library. It differs from a raw squared FFT or power spectrum. Sample rate, window normalization and one-sided scaling are part of the finite estimator.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27848-27854.

See also. Periodogram, Welch PSD, Sample rate.

Precision allocation

General meaning. Selection of computation precision under a stated error-and-cost model.

In this library. A model's bound and a measured machine runtime are different quantities.

Source. Chapter 30 (explanatory anchor `krylov-precision-compilation-and-scheduling`); frozen reference-source Markdown lines 26683-26687.

See also. Resource budget, Pareto frontier.

Prime field

General meaning. The field of residues modulo a prime.

In this library. The constructor's prime validation is part of the contract. A residue-ring instance with arbitrary modulus is not interchangeable.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16932-16938.

See also. Residue ring, Finite field. **Notation:** NM-005.

Prime-power kernel

General meaning. A finite combinatorial coefficient rule evaluated modulo a declared prime power.

In this library. The compiler records valuation, unit, residue and support. It does not construct a complete p-adic field.

Source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20578-20582.

See also. Kummer valuation, Residue ring. **Notation:** NM-038.

Projector

General meaning. An endomorphism satisfying its idempotence identity in the local scalar domain.

In this library. The guide reserves the word for idempotent maps. A redundant reconstruction component is not a projector merely because its components sum to identity.

Source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 356-362.

See also. Packet system, Reconstruction component. **Notation:** NM-008.

Provenance

General meaning. Information about the origin and declared classification of a mathematical claim.

In this library. Qualified-name metadata and author-supplied claim status are not a fresh proof audit.

Source. Chapter 62 (explanatory anchor `chapter-62.-provenance-registries-and-extensions`); frozen reference-source Markdown lines 46334-46338.

See also. Claim status, Qualified name, Source checksum.

q-Kummer decomposition

General meaning. A branch-sensitive valuation and unit analysis for Gaussian-binomial data.

In this library. Ordinary prime valuation, cyclotomic order and the value of q must be distinguished.

Source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20578-20582.

See also. Kummer valuation, Unit part.

Quadrature

General meaning. A weighted finite evaluation rule approximating or exactly integrating a stated function class.

In this library. Polynomial exactness degree is not exactness for arbitrary functions, and a numerical rule needs its error assumptions.

Source. Chapter 48 (explanatory anchor `integration-providers-and-quadrature`); frozen reference-source Markdown lines 41957-41961.

See also. Integration provider, Moment.

Qualification

General meaning. Acceptance against an explicitly named set of release or platform gates.

In this library. An aggregate pass can depend on which gates were required. It must be read with coverage and environment, not as universal support.

Source. Chapter 73 (explanatory anchor `platform-and-release-qualification`); frozen reference-source Markdown lines 47793-47797.

See also. Backend, Verification suite, Required gate.

Qualified name

General meaning. An object's name together with the namespace that identifies its route.

In this library. Reused theorem identifiers need qualified owner and source identity for disambiguation. Import aliases can refer to one implementation.

Source. Chapter 62 (explanatory anchor `chapter-62.-provenance-registries-and-extensions`); frozen reference-source Markdown lines 46335-46341.

See also. Provenance, Alias, Theorem identifier.

Quantum channel

General meaning. A linear map on operators satisfying the required positivity and normalization conditions in the intended model.

In this library. Kraus/Choi representations and the finite checks must be interpreted with their conventions and tolerances.

Source. Chapter 54 (explanatory anchor `chapter-54.-circuits-channels-and-open-dynamics`); frozen reference-source Markdown lines 44831-44837.

See also. Choi matrix, Kraus operator. **Notation:** NM-054.

Quantum code

General meaning. A code subspace together with a declared finite error family.

In this library. The constructor validates the projector and errors, while correctability is checked by the separate finite criterion.

Source. Chapter 55 (explanatory anchor `chapter-55.-error-correction-and-effective-dynamics`); frozen reference-source Markdown lines 45069-45075.

See also. Knill-Laflamme condition, Kraus operator. **Notation:** NM-055.

Quotient metric

General meaning. A metric interpreted on coefficient classes after identifying gauge-equivalent representatives.

In this library. A coefficient-space expression is not automatically a positive definite metric on all redundant coordinates.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15507-15513.

See also. Coefficient gauge, Analysis-synthesis system.

Ramification tower

General meaning. A represented sequence of local ramification data and compatibility records.

In this library. External descent, phase or realization assumptions remain explicit where not proved by the finite construction.

Source. Chapter 58 (explanatory anchor `chapter-58.-finite-image-ramification-and-completion-models`); frozen reference-source Markdown lines 45602-45606.

See also. Conditional result, Completion gate.

Reconstruction component

General meaning. One contribution to a physical reconstruction through selected coefficient coordinates.

In this library. Components sum to the reconstruction operator, but individual redundant components need not square to themselves.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15792-15798.

See also. Projector, Canonical dual. **Notation:** NM-010.

Recovery

General meaning. Reconstruction of missing or transformed information under a stated finite model.

In this library. Identifiability assumptions and failure diagnostics remain necessary. A returned candidate need not imply unique recovery.

Source. Chapter 36 (explanatory anchor `singular-packets-and-recovery`); frozen reference-source Markdown lines 30764-30768.

See also. Singular packet, Residual.

Recurrence coordinates

General meaning. Coordinates built from a finite recurrence or state-space realization.

In this library. Recurrence order, seeds and reconstruction map must match. This is not a proof of an empirically fitted global sequence rule.

Source. Chapter 18 (explanatory anchor `combinatorial-recurrence-and-state-space-coordinates`); frozen reference-source Markdown lines 12605-12609.

See also. Linear recurrence, State-space realization.

Refinement defect

General meaning. A discrepancy measuring failure of an operator relation across a refinement map.

In this library. It is not the same as numerical roundoff: a nonzero exact defect can record a genuine obstruction.

Source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6761-6767.

See also. Defect, Packet refinement.

Refinement tower

General meaning. A finite chain of compatible adjacent packet refinements.

In this library. Stored finite levels do not establish the existence or convergence of an infinite inverse limit.

Source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6758-6764.

See also. Packet refinement, Finite lift forest.

Renderer

General meaning. A transformation of a document model into presentation text.

In this library. Rendering is distinct from a writer's path, overwrite and asset policy, and from mathematical object deserialization.

Source. Chapter 60 (explanatory anchor `chapter-60.-renderers-and-writers`); frozen reference-source Markdown lines 46031-46035.

See also. Document model, Portable record.

Reproducibility

General meaning. The ability to repeat a specified construction from recorded inputs and an environment.

In this library. Byte reproduction, semantic replay, package isolation and dependency isolation are distinct claims.

Source. Chapter 70 (explanatory anchor `chapter-70.-export-and-reproducibility-recipes`); frozen reference-source Markdown lines 47369-47373.

See also. Source checksum, Qualification.

Required gate

General meaning. An acceptance condition selected as mandatory by a qualification profile.

In this library. An empty required set can produce a favorable aggregate with no successful GPU execution. Inspect the actual backend records.

Source. Chapter J (explanatory anchor `appendix-j-backends-dependencies`); frozen reference-source Markdown lines 106481-106487.

See also. Qualification, Completion gate.

Resampling

General meaning. Conversion between declared sampling grids using specified interpolation/filtering rules.

In this library. Sample-rate conversion is distinct from a packet refinement that keeps the same ambient vector space.

Source. Chapter 34 (explanatory anchor `resampling-and-adaptive-filters`); frozen reference-source Markdown lines 29105-29109.

See also. Polyphase refinement, Signal.

Research API

General meaning. An exploratory interface surface with its own additive compatibility policy.

In this library. Research exports can implement exact finite identities. Their tier does not certify a new theorem.

Source. Chapter 7 (explanatory anchor `public-api-tiers`); frozen reference-source Markdown lines 2616-2622.

See also. API tier, Exactness, Provenance.

Residual

General meaning. A discrepancy between the compared quantities in a stated norm or algebra.

In this library. Interpret each named residual locally. A zero residual for one fixture does not establish all hypotheses of an operator identity.

Source. Chapter 5 (explanatory anchor `certificates-and-result-types`); frozen reference-source Markdown lines 1545-1551.

See also. Tolerance, Numerical result, Defect. **Notation:** NM-050.

Residue coordinate

General meaning. A finite address classified by its congruence class modulo a chosen integer.

In this library. Residue lanes and their quotient indices preserve a declared finite indexing convention.

Source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8019-8023.

See also. Lane, CRT coordinates, Polyphase decomposition. **Notation:** NM-026.

Residue ring

General meaning. Integers modulo a positive modulus with modular arithmetic.

In this library. Not every nonzero element is invertible when the modulus is composite.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16973-16979.

See also. Unit, Prime field.

Resource budget

General meaning. A set of declared local bounds on selected operations or representations.

In this library. Some checks occur after traversal or allocation. A stored budget is not a universal parser, process-memory or hostile-input limit.

Source. Chapter K (explanatory anchor `appendix-k-resource-budgets`); frozen reference-source Markdown lines 108159-108165.

See also. Approximation budget, Memory estimate.

Rooted tree

General meaning. A finite rooted combinatorial structure used to organize nonlinear compositions.

In this library. Ordered nonlinear trees, leaf counts and heights have their own conventions. They are not interchangeable with wavelet packet trees.

Source. Chapter 39 (explanatory anchor `nonlinear-trees-and-graded-operations`); frozen reference-source Markdown lines 33404-33408.

See also. Tree height, Wavelet packet tree.

Sample rate

General meaning. The rate connecting sample index with physical time or frequency units.

In this library. FFT-bin indices are not physical frequencies without the corresponding rate and transform length.

Source. Chapter 31 (explanatory anchor `signal-conventions-windows-and-framing`); frozen reference-source Markdown lines 27208-27214.

See also. Signal, Periodogram.

Scalar domain

General meaning. The set of scalars and permitted arithmetic operations used by a construction.

In this library. Integer, rational, residue, prime-field and truncated prime-power domains have different units and inverses.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16961-16967.

See also. Unit, Exact arithmetic, Backend. **Notation:** NM-001, NM-004, NM-020.

Section operator

General meaning. Selection of a residue lane from a coefficient sequence.

In this library. Lane index, radix and normalization determine which coefficients and weights are retained.

Source. Chapter 22 (explanatory anchor `normalized-generating-functions`); frozen reference-source Markdown lines 17858-17864.

See also. Cartier operator, Lane.

Seed system

General meaning. A family of vectors used to generate a representation under an operator algebra.

In this library. Generation refers to the finite orbit hull, not arbitrary learning or discovery of generators.

Source. Chapter 10 (explanatory anchor `operator-algebras-and-seed-systems`); frozen reference-source Markdown lines 4725-4731.

See also. Orbit hull, Cyclic vector.

Sequence

General meaning. An indexed rule assigning values to natural-number indices.

In this library. The package evaluates finite requests and may cache values. Its exact metadata does not inspect or prove the evaluator's arithmetic.

Source. Chapter 26 (explanatory anchor `exact-sequence-execution`); frozen reference-source Markdown lines 23427-23431.

See also. Linear recurrence, Automatic sequence.

Sequence model

General meaning. A finite declared or inferred representation used for sequence evaluation.

In this library. A recurrence fitted to a finite prefix is extrapolation unless an independent justification establishes the rule globally.

Source. Chapter 26 (explanatory anchor `exact-sequence-execution`); frozen reference-source Markdown lines 23434-23440.

See also. Linear recurrence, Heuristic.

Set partition

General meaning. A division of a finite set of direction positions into disjoint nonempty blocks.

In this library. Block ordering conventions used for deterministic enumeration do not change the underlying partition, but affect stored addresses.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32713-32719.

See also. Faà di Bruno composition, Multi-index. **Notation:** NM-051.

Signal

General meaning. A finite array interpreted with a declared sampling and axis convention.

In this library. Time is axis zero in the documented signal layer. Boundary extension and dtype are part of each operation.

Source. Chapter 31 (explanatory anchor `signal-conventions-windows-and-framing`); frozen reference-source Markdown lines 27201-27207.

See also. Frame, Sample rate. **Notation:** NM-040.

Singular packet

General meaning. A packet associated with the declared singularity or recovery model.

In this library. Its meaning depends on the specified finite transform and diagnostic, not simply a numerically singular matrix.

Source. Chapter 36 (explanatory anchor `singular-packets-and-recovery`); frozen reference-source Markdown lines 30764-30768.

See also. Recovery, Packet system.

Smith coordinates

General meaning. Integer-lattice coordinates obtained using a Smith normal form and unimodular changes of basis.

In this library. The diagonal invariant factors and basis changes carry the meaning, not a floating eigenvalue decomposition.

Source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8019-8023.

See also. Unimodular transform, Lattice quotient.

Smooth packet transport

General meaning. Transport of a moving packet decomposition under a declared finite differentiable path.

In this library. Smoothness and derivative assumptions belong to the input model. Sampled checks do not prove arbitrary global regularity.

Source. Chapter 44 (explanatory anchor `smooth-packet-transport`); frozen reference-source Markdown lines 38677-38681.

See also. Kato transport, Packet jet.

Snapshot

General meaning. A finite stored capture of coefficients or state at a specified point in an execution.

In this library. A snapshot is not a live callback and may cover only a declared finite order or prefix.

Source. Chapter 43 (explanatory anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`); frozen reference-source Markdown lines 37417-37423.

See also. Frozen record, Stream manifest.

Source checksum

General meaning. A content fingerprint computed over a specified byte or canonical-data representation.

In this library. A matching digest binds content identity, not semantic truth, authorship or authenticity.

Source. Chapter 75 (explanatory anchor `freeze-and-finalization-protocol`); frozen reference-source Markdown lines 110456-110462.

See also. Canonical JSON, Reproducibility. **Notation:** NM-060.

Spectrogram

General meaning. A time-frequency display derived from STFT values, often by magnitude or power.

In this library. A power spectrogram is not automatically a power spectral density with physical units.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27842-27848.

See also. STFT, Periodogram.

Stable API

General meaning. An interface governed by a declared compatibility contract.

In this library. The stable namespace is a selected surface. A stable symbol can perform numerical or conditional work.

Source. Chapter 7 (explanatory anchor `public-api-tiers`); frozen reference-source Markdown lines 2599-2605.

See also. API tier, Beta API, Research API.

Stable core

General meaning. Candidates that survive every represented compatibility level in a finite lift forest.

In this library. Stable here concerns the finite forest, not the stable API tier or asymptotic dynamical stability.

Source. Chapter 56 (explanatory anchor `chapter-56.-finite-deformation-systems`); frozen reference-source Markdown lines 45202-45208.

See also. Finite lift forest, Stable API.

State-space realization

General meaning. A finite state update and observation representation of a system or sequence.

In this library. The selected coordinates and state dimension are explicit, and minimality is not implied merely by successful construction.

Source. Chapter 18 (explanatory anchor `combinatorial-recurrence-and-state-space-coordinates`); frozen reference-source Markdown lines 12605-12609.

See also. Recurrence coordinates, Coordinate transform.

STFT

General meaning. A short-time Fourier transform of framed signal data.

In this library. The implementation uses local-frame Fourier coordinates. FFT length, hop, one/two-sided output and phase convention must be read together.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27654-27660.

See also. Frame, Spectrogram, Inverse STFT. **Notation:** NM-041, NM-042, NM-043, NM-044, NM-045.

Stream manifest

General meaning. Metadata describing a chunked finite stream, its progress and content identities.

In this library. Paused, complete and loadable states must be distinguished. A valid partial stream is not a completed reconstruction.

Source. Chapter 43 (explanatory anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`); frozen reference-source Markdown lines 37929-37935.

See also. Snapshot, Source checksum.

Structured operator

General meaning. An operator stored in a representation exploiting a stated algebraic structure.

In this library. Apply, materialize, adjoint, storage and cost models are separate interfaces. Dense materialization can erase the storage advantage.

Source. Chapter 29 (explanatory anchor `structured-and-low-rank-operators`); frozen reference-source Markdown lines 26375-26381.

See also. Low-rank factorization, Kronecker product.

Supported lift

General meaning. A coefficient-space map representing a physical map on the supported coefficient subspaces.

In this library. Support projectors and possible transition bridges are required for the correct composition law.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15501-15507.

See also. Coefficient projector, Transition bridge.

Survival operator

General meaning. Evolution restricted or projected to a chosen retained sector.

In this library. Loss of norm or leakage can reflect coupling to excluded sectors rather than failure of the full evolution law.

Source. Chapter 46 (explanatory anchor `feshbach-reduction-memory-and-survival`); frozen reference-source Markdown lines 40656-40660.

See also. Memory kernel, Leakage.

Symbol card

General meaning. A structured reference record for one public symbol, its type, assumptions, behavior and evidence.

In this library. Canonical placement is separate from the number of aliases exposing the same object.

Source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 253-259.

See also. Qualified name, API tier. **Notation:** NM-018.

Symmetry packet

General meaning. A sector resolved by projectors associated with declared finite symmetry data.

In this library. Sector labels do not prove a global symmetry or continuum spectral theorem.

Source. Chapter 53 (explanatory anchor `chapter-53.-finite-quantum-foundations`); frozen reference-source Markdown lines 44600-44606.

See also. Packet system, Observable.

Synthesis map

General meaning. A map from coefficients back to physical vectors.

In this library. Reconstruction requires synthesis after analysis to equal the physical identity. Analysis after synthesis need only be a projection.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15521-15527.

See also. Analysis map, Coefficient projector. **Notation:** NM-029.

Taylor truncation

General meaning. A finite derivative expansion through a declared order.

In this library. Exact computation of its coefficients does not by itself provide an analytic remainder bound or infinite-series convergence.

Source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32538-32544.

See also. Packet jet, Truncation.

Tensor coordinate transport

General meaning. Coordinate conversion induced on a tensor product of factor spaces.

In this library. Factor order and flattening conventions matter. A Kronecker product with reversed factors generally represents another map.

Source. Chapter 19 (explanatory anchor `spectral-packet-tensor-and-operator-transport`); frozen reference-source Markdown lines 14168-14172.

See also. Kronecker product, Coordinate transform. **Notation:** NM-064.

Theorem identifier

General meaning. A source label used to navigate a stated claim or construction.

In this library. The finite label index includes definitions, engineering checks and conditional records. IDs can be reused and are not globally unique proof keys.

Source. Chapter H (explanatory anchor `appendix-h-certificate-theorem-index`); frozen reference-source Markdown lines 96760-96766.

See also. Qualified name, Certificate.

Tolerance

General meaning. A threshold used for specified numerical comparisons.

In this library. It belongs to a particular norm, scale and procedure. It neither changes exact equality nor supplies a universal error bound.

Source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 346-352.

See also. Residual, Exact arithmetic.

Transfer block

General meaning. The target-by-source component of an operator after output and input projection.

In this library. The index order is target then source. The block contains coefficients, while a transfer graph keeps only support information.

Source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5637-5643.

See also. Packet operator, Transfer graph. **Notation:** NM-023.

Transfer graph

General meaning. A directed graph recording active source-to-target transfers.

In this library. Numerical support is relative to the active tolerance. Boolean support forgets weights and possible cancellation between paths.

Source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5657-5663.

See also. Transfer block, Transfer path.

Transfer path

General meaning. A legal sequence of packet transitions through a finite operator product.

In this library. Its contribution is an ordered block product. Existence of a graph path alone does not ensure a nonzero total contribution.

Source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5664-5670.

See also. Transfer graph, Packet operator.

Transition bridge

General meaning. A map reconciling different intermediate coefficient presentations during composition.

In this library. Omitting it can produce the wrong coefficient product even when the underlying physical maps compose.

Source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15502-15508.

See also. Supported lift, Coordinate transform.

Tree height

General meaning. A depth measure defined by the selected rooted-tree convention.

In this library. Use the library's leaf/root convention before interpreting height-bounded enumeration and its resource guard.

Source. Chapter 39 (explanatory anchor `nonlinear-trees-and-graded-operations`); frozen reference-source Markdown lines 33476-33482.

See also. Rooted tree, Resource budget.

Truncated p-adic value

General meaning. A finite-precision residue model modulo a prime power.

In this library. Increasing a requested precision cannot recover information that was already discarded by reduction.

Source. Chapter 25 (explanatory anchor `local-arithmetic-models`); frozen reference-source Markdown lines 21835-21841.

See also. Valuation, Truncation. **Notation:** NM-006.

Truncation

General meaning. Restriction to a declared finite degree, order, length or precision.

In this library. Its meaning is domain-specific. Discarded high coefficients and discarded modular information are different operations.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16885-16891.

See also. Formal series, Truncated p-adic value.

Typed expression

General meaning. A finite symbolic value or map carrying domain, codomain and basis semantics.

In this library. Shape agreement alone does not establish compatible types. Opaque callbacks are not substituted for branded exact primitives.

Source. Chapter 50 (explanatory anchor `typed-finite-expression-model`); frozen reference-source Markdown lines 42982-42986.

See also. Basis witness, Normal form. **Notation:** NM-019.

Unimodular transform

General meaning. An integer matrix invertible over the integers, with determinant a unit.

In this library. It preserves the integer lattice rather than merely preserving a real vector space.

Source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8378-8384.

See also. Smith coordinates, Lattice quotient.

Unit

General meaning. A scalar with a multiplicative inverse in its declared domain.

In this library. A nonzero residue modulo a composite modulus can be a nonunit. Rational nonzero values and prime-field nonzero values have different domain rules.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 17012-17018.

See also. Scalar domain, Residue ring.

Unit part

General meaning. The factor remaining after removing the relevant prime-power valuation.

In this library. It is evaluated in the declared finite precision, and must not be conflated with the full residue.

Source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20580-20586.

See also. Valuation, Prime-power kernel.

Validity flag

General meaning. A stored indication that a producer regarded its local predicate as satisfied.

In this library. The base certificate currently accepts truthy values. Stored validity is not independent witness checking, and loading it does not prove the claim.

Source. Chapter H (explanatory anchor `appendix-h-certificate-theorem-index`); frozen reference-source Markdown lines 96539-96545.

See also. Certificate, Portable record.

Valuation

General meaning. A measure of divisibility by a chosen prime, or the corresponding local order.

In this library. Zero conventions differ by API: some valuation methods return infinity and others reject zero. The local method contract controls.

Source. Chapter 25 (explanatory anchor `local-arithmetic-models`); frozen reference-source Markdown lines 21819-21825.

See also. Unit part, Truncated p-adic value.

Verification suite

General meaning. A named collection of finite checks.

In this library. Suite names can dispatch to historical aggregates. A suite is not automatically the full source test run.

Source. Chapter 71 (explanatory anchor `verification-suites`); frozen reference-source Markdown lines 47529-47533.

See also. Qualification, Finite certificate.

Wavelet packet tree

General meaning. A hierarchy of recursively split wavelet/filter-bank coefficient subspaces.

In this library. The finite tree, boundary rule and selected basis determine reconstruction. It is not the nonlinear rooted-tree algebra.

Source. Chapter 35 (explanatory anchor `filter-banks-wavelets-and-packet-trees`); frozen reference-source Markdown lines 29632-29636.

See also. Best basis, Rooted tree.

Weighted monomial basis

General meaning. A basis with degree-dependent monomial normalization.

In this library. The basis element is z to the n divided by gamma_n. The stored coefficient is not generally the ordinary monomial coefficient.

Source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 16910-16916.

See also. Normalized coefficient, Formal series. **Notation:** NM-034, NM-035.

Weighted transfer graph

General meaning. A transfer graph with weights representing additional arithmetic or operator data.

In this library. Weight meaning is supplied by the local model, not by the Boolean graph alone.

Source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6761-6767.

See also. Transfer graph, Valuation.

Welch PSD

General meaning. An averaged, windowed finite power spectral density estimate.

In this library. Averaging parameters, segment lengths and scaling are part of the estimate. The result is not an exact underlying stochastic spectrum.

Source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27890-27896.

See also. Periodogram, Coherence.

Window

General meaning. A finite weighting sequence applied to a signal segment.

In this library. Window metrics, overlap support and reconstruction conditions are distinct; a named window alone does not ensure invertible framing.

Source. Chapter 31 (explanatory anchor `signal-conventions-windows-and-framing`); frozen reference-source Markdown lines 27201-27205.

See also. Frame, Overlap-add.

Zero certificate

General meaning. A diagnostic record for the supplied or computed zero representatives.

In this library. Small residuals and ordering do not establish that every zero has been found or prove a global counting theorem.

Source. Chapter 27 (explanatory anchor `cyclic-analytic-systems`); frozen reference-source Markdown lines 24957-24963.

See also. Residual, Conditional result.

M.5 Notation register: glyph, speech and local sense

A symbol is identified by **display + local domain + explanatory anchor**, not by typography alone. The collision-family key supports lookup and does not claim that all strings in that family are literally identical. In particular, plain, calligraphic, bold and sans-serif versions can denote different objects.

NM-001. integers

Display: $\mathbb{Z}$.

Local meaning. Integer scalar domain. A quotient-ring notation must include its modulus.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 338-344.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Scalar domain. **Other senses in this notation family:** NM-002, NM-003, NM-004.

NM-002. rationals

Display: $\mathbb{Q}$.

Local meaning. Rational scalars. The implemented exact coordinate layer uses finite rational tuples.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 338-344.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Exact arithmetic. **Other senses in this notation family:** NM-001, NM-003, NM-004.

NM-003. reals

Display: $\mathbb{R}$.

Local meaning. Mathematical real scalars; floating arrays approximate real arithmetic rather than realize all real numbers exactly.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 338-344.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Numerical result. **Other senses in this notation family:** NM-001, NM-002, NM-004.

NM-004. complex numbers

Display: $\mathbb{C}$.

Local meaning. Mathematical complex scalars. Transpose and conjugate transpose differ on these scalars.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 338-344.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Scalar domain. **Other senses in this notation family:** NM-001, NM-002, NM-003.

NM-005. F p

Display: $\mathbb{F}_p$.

Local meaning. Residues in the prime field of characteristic p. Primality is part of the intended domain.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 338-344.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Prime field. **Other senses in this notation family:** NM-006, NM-024, NM-025, NM-056.

NM-006. integers modulo p to the k

Display: $\mathbb{Z}/p^k\mathbb{Z}$.

Local meaning. A finite prime-power residue domain, not the complete p-adic field.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 338-344.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Truncated p-adic value. **Other senses in this notation family:** NM-005, NM-024, NM-025, NM-056.

NM-007. A adjoint

Display: A^*.

Local meaning. Conjugate transpose under the global matrix convention. A different metric must be stated explicitly.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 341-347.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Adjoint. **Other senses in this notation family:** NM-059.

NM-008. identity on X

Display: I_X.

Local meaning. Identity map on the indicated space X. Its dimensions follow the type, not a context-free scalar one.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 342-348.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Projector. **Other senses in this notation family:** NM-030.

NM-009. P sub i, packet projector

Display: P_i.

Local meaning. A packet projector only where the local chapter has declared that interpretation.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 343-349.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Packet system. **Other senses in this notation family:** NM-010, NM-017, NM-057.

NM-010. P sub i, coordinate selector

Display: P_i.

Local meaning. A local coordinate selector is not automatically a physical reconstruction component or the same map as a packet projector.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 343-349.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Reconstruction component. **Other senses in this notation family:** NM-009, NM-017, NM-057.

NM-011. T from A coordinates to B

Display: $T_{B\leftarrow A}$.

Local meaning. A map converting A coordinates to B coordinates. The arrow names source and target.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 348-354.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Coordinate transform. **Other senses in this notation family:** NM-012, NM-023, NM-052.

NM-012. T from B to C times T from A to B

Display: $T_{C\leftarrow B}T_{B\leftarrow A}$.

Local meaning. Composition applies A-to-B first. The following transformation multiplies on the left.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 352-358.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Coordinate transform. **Other senses in this notation family:** NM-011, NM-023, NM-052.

NM-013. exact evidence E

Display: E.

Local meaning. Editorial exact finite evidence class. It is not a coordinate space or a function expectation.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 414-420.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Exactness. **Other senses in this notation family:** NM-018, NM-055.

NM-014. numerical evidence N

Display: N.

Local meaning. Editorial numerical evidence class, not a signal length or truncation degree.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 414-420.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Numerical result. **Other senses in this notation family:** NM-040, NM-061.

NM-015. conditional evidence C

Display: C.

Local meaning. Editorial conditional evidence class, not the coefficient space C or complex scalars.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 414-420.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Conditional result. **Other senses in this notation family:** NM-045.

NM-016. heuristic evidence H

Display: H.

Local meaning. Editorial heuristic class, not a signal hop or a Hilbert space.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 414-420.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Heuristic. **Other senses in this notation family:** NM-041, NM-053.

NM-017. planned evidence P

Display: P.

Local meaning. Editorial planned class, not a packet projector or polynomial coordinate space.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 414-420.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Planned feature. **Other senses in this notation family:** NM-009, NM-010, NM-057.

NM-018. example record E

Display: $\mathfrak{E}$.

Local meaning. Input/hypothesis/action/output/certificate/failure/reproducibility example record. This is an editorial record, not an operator.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 317-323.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Symbol card. **Other senses in this notation family:** NM-013, NM-055.

NM-019. f maps X to Y

Display: $f : X \to Y$.

Local meaning. Typed map with stated domain and codomain. Equal dimensions alone do not identify the two named spaces.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 274-280.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Typed expression. No other notation record is assigned to this collision family.

NM-020. R m by n

Display: $R^{m\times n}$.

Local meaning. Matrices over the locally named scalar domain R. It does not force R to be the real numbers.

Domain and source. Chapter 1 (explanatory anchor `editorial-and-symbolic-grammar`); frozen reference-source Markdown lines 509-515.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Scalar domain. No other notation record is assigned to this collision family.

NM-021. operator grammar G

Display: $\mathsf{G} = (V, A, s, t)$.

Local meaning. Vertices, arrows and source/target maps of the typed operator quiver. Here A is an arrow set, not an analysis matrix.

Domain and source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3800-3806.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Operator grammar. **Other senses in this notation family:** NM-022, NM-028, NM-031, NM-047.

NM-022. generated algebra A

Display: $\mathcal{A}$.

Local meaning. The algebra generated by the declared operator family. Finite rank tests depend on backend and tolerance.

Domain and source. Chapter 10 (explanatory anchor `operator-algebras-and-seed-systems`); frozen reference-source Markdown lines 4714-4718.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Generated operator algebra. **Other senses in this notation family:** NM-021, NM-028, NM-031, NM-047.

NM-023. T j i equals Q j T P i

Display: $T_{ji} = Q_j T P_i$.

Local meaning. Transfer from input packet i to output packet j. The first block index is the target.

Domain and source. Chapter 11 (explanatory anchor `packet-systems-and-transfer-blocks`); frozen reference-source Markdown lines 5637-5643.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Transfer block. **Other senses in this notation family:** NM-011, NM-012, NM-052.

NM-024. coarse P a is the sum of its children

Display: $P_a = \sum_{b:p(b)=a} Q_b$.

Local meaning. Refinement compatibility on the same ambient space, with parent map p.

Domain and source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6751-6757.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Packet refinement. **Other senses in this notation family:** NM-005, NM-006, NM-025, NM-056.

NM-025. parent map p

Display: $p : B \to A$.

Local meaning. The parent of a fine packet label. This p is not an arithmetic prime.

Domain and source. Chapter 12 (explanatory anchor `refinement-towers`); frozen reference-source Markdown lines 6745-6751.

Spelling status. Normalized editorial display for the cited sense; not asserted to be a verbatim source formula.

Concept: Packet refinement. **Other senses in this notation family:** NM-005, NM-006, NM-024, NM-056.

NM-026. residue r channel at k

Display: $x_r[k] = x[r + Mk]$.

Local meaning. Residue-lane indexing under modulus M. Ragged channel lengths depend on the original finite length.

Domain and source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8054-8060.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Residue coordinate. **Other senses in this notation family:** NM-027, NM-043.

NM-027. nested address r plus M s

Display: $r + Ms$.

Local meaning. Positional nested address. It is not generally the Chinese-remainder representative.

Domain and source. Chapter 13 (explanatory anchor `residue-crt-lattice-and-smith-coordinates`); frozen reference-source Markdown lines 8028-8034.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Mixed-radix address. **Other senses in this notation family:** NM-026, NM-043.

NM-028. analysis A from X to C

Display: $A : X \to C$.

Local meaning. Analysis from physical space to coefficient space. Here C names a space and does not mean the complex field.

Domain and source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15519-15525.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Analysis map. **Other senses in this notation family:** NM-021, NM-022, NM-031, NM-047.

NM-029. synthesis S from C to X

Display: $S : C \to X$.

Local meaning. Synthesis from coefficients to physical vectors.

Domain and source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15521-15527.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Synthesis map. No other notation record is assigned to this collision family.

NM-030. S A equals physical identity

Display: $SA = I_X$.

Local meaning. Verified left-inverse relation for the physical presentation. Bare construction can store a proposal that fails it.

Domain and source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15523-15529.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Analysis-synthesis system. **Other senses in this notation family:** NM-008.

NM-031. A S, coefficient projector

Display: AS.

Local meaning. Analysis after synthesis is idempotent when SA is identity, but is not generally the full coefficient identity.

Domain and source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15500-15506.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Coefficient projector. **Other senses in this notation family:** NM-021, NM-022, NM-028, NM-047.

NM-032. kernel of synthesis S

Display: ker S.

Local meaning. Coefficient changes invisible after synthesis. Gauge directions are not necessarily zero coefficient vectors.

Domain and source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15501-15507.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Coefficient gauge. No other notation record is assigned to this collision family.

NM-033. Frobenius norm of reconstruction defect

Display: $\|SA - I_n\|_F$.

Local meaning. The stated left-inverse residual. The subscript F denotes a norm, not a finite-field Frobenius map.

Domain and source. Chapter 20 (explanatory anchor `analysis-synthesis-and-redundant-frames`); frozen reference-source Markdown lines 15615-15621.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Frobenius norm. **Other senses in this notation family:** NM-044, NM-060.

NM-034. gamma sub n

Display: γ_n.

Local meaning. Nonzero degree-n normalization denominator with gamma_0 equal to one.

Domain and source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 17069-17075.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Weighted monomial basis. No other notation record is assigned to this collision family.

NM-035. w n equals inverse gamma n

Display: $w_n = \gamma_n^{-1}$.

Local meaning. Monomial weight reciprocal to the normalization denominator. Do not confuse it with a signal window.

Domain and source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 17076-17082.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Weighted monomial basis. No other notation record is assigned to this collision family.

NM-036. ordinary coefficient c n

Display: $c_n = a_n/\gamma_n$.

Local meaning. Conversion from stored normalized coefficient to ordinary monomial coefficient.

Domain and source. Chapter 22 (explanatory anchor `normalized-generating-functions`); frozen reference-source Markdown lines 17856-17862.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Normalized coefficient. No other notation record is assigned to this collision family.

NM-037. z power n divided by n factorial

Display: $z^n/n!$.

Local meaning. Exponential normalization. Multiplication on stored coefficients carries binomial factors.

Domain and source. Chapter 21 (explanatory anchor `formal-series-and-weighted-bases`); frozen reference-source Markdown lines 17206-17212.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Hurwitz series. **Other senses in this notation family:** NM-051.

NM-038. p to precision r

Display: p^r.

Local meaning. Prime-power modulus in the specified finite arithmetic branch. r here is precision, not a residue label or derivative order.

Domain and source. Chapter 24 (explanatory anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`); frozen reference-source Markdown lines 20589-20595.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Prime-power kernel. **Other senses in this notation family:** NM-046.

NM-039. Krylov space K k of A and b

Display: $\mathcal{K}_k(A, b)$.

Local meaning. Span of b and its first k-1 iterated images under A. The callback hypotheses remain explicit.

Domain and source. Chapter 30 (explanatory anchor `krylov-precision-compilation-and-scheduling`); frozen reference-source Markdown lines 26693-26699.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Krylov subspace. **Other senses in this notation family:** NM-042.

NM-040. length N signal x

Display: $x \in \mathbb{K}^N$.

Local meaning. Finite real or complex signal. N is a sample count in this sense.

Domain and source. Chapter 31 (explanatory anchor `signal-conventions-windows-and-framing`); frozen reference-source Markdown lines 27204-27210.

Spelling status. Normalized editorial display for the cited sense; not asserted to be a verbatim source formula.

Concept: Signal. **Other senses in this notation family:** NM-014, NM-061.

NM-041. hop H

Display: H.

Local meaning. Number of sample positions between successive frames. It is not a Hamiltonian or heuristic evidence class.

Domain and source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27644-27650.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: STFT. **Other senses in this notation family:** NM-016, NM-053.

NM-042. FFT length K

Display: K.

Local meaning. Transform length, at least the stated frame length. It need not equal the original signal length.

Domain and source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27644-27650.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: STFT. **Other senses in this notation family:** NM-039.

NM-043. frame count M

Display: M.

Local meaning. Number of frames in the returned array. Elsewhere M can name an arithmetic modulus or memory estimate.

Domain and source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27644-27650.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: STFT. **Other senses in this notation family:** NM-026, NM-027.

NM-044. frequency-bin count F

Display: F.

Local meaning. Count determined by one-sided or two-sided transform conventions. This F is not a nonlinear map.

Domain and source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27644-27650.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: STFT. **Other senses in this notation family:** NM-033, NM-060.

NM-045. complex frame by frequency array

Display: $\mathbb{C}^{M \times F}$.

Local meaning. STFT output with frame axis first and frequency axis second.

Domain and source. Chapter 32 (explanatory anchor `time-frequency-and-spectral-analysis`); frozen reference-source Markdown lines 27657-27663.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: STFT. **Other senses in this notation family:** NM-015.

NM-046. r-th derivative of F at x

Display: $D^r F(x)$.

Local meaning. An r-linear derivative evaluation in the declared provider model. The index r is derivative order here.

Domain and source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32593-32599.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Derivative provider. **Other senses in this notation family:** NM-038.

NM-047. order r address space

Display: $\mathcal{A}_r = B \times A^r$.

Local meaning. One output packet label and an ordered r-tuple of input labels. Here A and B are label sets.

Domain and source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32582-32588.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Jet address. **Other senses in this notation family:** NM-021, NM-022, NM-028, NM-031.

NM-048. alpha, output and input packet address

Display: $\alpha = (b; a_1, \dots, a_r)$.

Local meaning. A packet-jet address, not automatically a polynomial-exponent multi-index.

Domain and source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32586-32592.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Jet address. No other notation record is assigned to this collision family.

NM-049. addressed order r packet jet

Display: $J^{(r)}_{b;a_1,\dots,a_r}(x)$.

Local meaning. The output projection of a derivative evaluated on projected input directions.

Domain and source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32592-32598.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Packet jet. No other notation record is assigned to this collision family.

NM-050. rho rec, reconstruction residual

Display: ρ_{rec}.

Local meaning. Norm of direct derivative evaluation minus the complete addressed reconstruction. It is not a density matrix.

Domain and source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32661-32667.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Residual. **Other senses in this notation family:** NM-054.

NM-051. r factorial

Display: $r!$.

Local meaning. Number of paired permutations used by the finite symmetry check, not a claim that every jet algorithm has this cost.

Domain and source. Chapter 38 (explanatory anchor `packet-jets-and-fauxe0-di-bruno-composition`); frozen reference-source Markdown lines 32628-32634.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Set partition. **Other senses in this notation family:** NM-037.

NM-052. matrix semigroup T at t

Display: $T(t) = e^{tA}$.

Local meaning. Autonomous finite matrix evolution. It is not a coordinate-change matrix merely because it is called T.

Domain and source. Chapter 45 (explanatory anchor `matrix-dynamics`); frozen reference-source Markdown lines 39419-39425.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Matrix dynamics. **Other senses in this notation family:** NM-011, NM-012, NM-023.

NM-053. Hilbert space H

Display: $\mathcal{H}$.

Local meaning. Finite complex Hilbert space of the quantum model. Distinct from hop H and heuristic class H.

Domain and source. Chapter 53 (explanatory anchor `chapter-53.-finite-quantum-foundations`); frozen reference-source Markdown lines 44607-44613.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Observable. **Other senses in this notation family:** NM-016, NM-041.

NM-054. density rho

Display: ρ.

Local meaning. Density operator in the finite open-system model. This is not the packet reconstruction residual.

Domain and source. Chapter 54 (explanatory anchor `chapter-54.-circuits-channels-and-open-dynamics`); frozen reference-source Markdown lines 44832-44838.

Spelling status. Normalized editorial display for the cited sense; not asserted to be a verbatim source formula.

Concept: Quantum channel. **Other senses in this notation family:** NM-050.

NM-055. error E i

Display: E_i.

Local meaning. A supplied error operator. E here is not the exactness class or editorial example record.

Domain and source. Chapter 55 (explanatory anchor `chapter-55.-error-correction-and-effective-dynamics`); frozen reference-source Markdown lines 45070-45076.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Quantum code. **Other senses in this notation family:** NM-013, NM-018.

NM-056. finite field p to n

Display: $\mathbb{F}_{p^n}$.

Local meaning. Extension field represented by a supplied polynomial basis and valid modulus polynomial.

Domain and source. Chapter 57 (explanatory anchor `chapter-57.-local-finite-langlands-packets`); frozen reference-source Markdown lines 45439-45445.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Finite field. **Other senses in this notation family:** NM-005, NM-006, NM-024, NM-025.

NM-057. polynomial coordinate space P n B

Display: P_n^B.

Local meaning. Degree-through-n polynomial coordinate space in an explicit graded basis B. Not a packet projector.

Domain and source. Chapter 50 (explanatory anchor `typed-finite-expression-model`); frozen reference-source Markdown lines 43003-43009.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Basis witness. **Other senses in this notation family:** NM-009, NM-010, NM-017.

NM-058. normal form of expression e

Display: $\mathrm{NF}(e)$.

Local meaning. Exact vector or matrix denotation of an accepted closed typed expression.

Domain and source. Chapter 51 (explanatory anchor `expression-evaluation-and-certification`); frozen reference-source Markdown lines 43523-43529.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Normal form. No other notation record is assigned to this collision family.

NM-059. document metadata and block sequence

Display: $\mathcal{D} = \mathcal{M} \times \mathcal{B}^*$.

Local meaning. A document's metadata and finite ordered block buffer. Star here means finite sequence construction, not adjoint.

Domain and source. Chapter 59 (explanatory anchor `chapter-59.-mathematical-document-model`); frozen reference-source Markdown lines 45886-45892.

Spelling status. Normalized editorial display for the cited sense; not asserted to be a verbatim source formula.

Concept: Document model. **Other senses in this notation family:** NM-007.

NM-060. freeze record F

Display: $F = (v, \mathcal{I}, h, \mathcal{R})$.

Local meaning. Version, inventory, digests and reconciliation items of a documentation freeze.

Domain and source. Chapter 75 (explanatory anchor `freeze-and-finalization-protocol`); frozen reference-source Markdown lines 110452-110458.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Source checksum. **Other senses in this notation family:** NM-033, NM-044.

NM-061. notation record N

Display: $N = (glyph, spoken, definition, first_anchor, domain, collisions, see_also)$.

Local meaning. The retained editorial schema for a notation entry. It is not a numerical dimension.

Domain and source. Chapter 88 (explanatory anchor `export-persistence-cli-recipes-verification-and-publication`); frozen reference-source Markdown lines 117957-117963.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Coverage contract. **Other senses in this notation family:** NM-014, NM-040.

NM-062. glossary record G

Display: $G = (term, definition, package_meaning, classical_meaning, anchors, symbols)$.

Local meaning. The retained editorial glossary schema. It is not the operator quiver G.

Domain and source. Chapter 88 (explanatory anchor `export-persistence-cli-recipes-verification-and-publication`); frozen reference-source Markdown lines 117958-117964.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Coverage contract. No other notation record is assigned to this collision family.

NM-063. equivalent under a local relation

Display: $\sim$.

Local meaning. Read the relation's domain and binder or gauge convention. A generic equivalence glyph alone does not assert object identity.

Domain and source. Chapter 50 (explanatory anchor `typed-finite-expression-model`); frozen reference-source Markdown lines 43318-43324.

Spelling status. Normalized editorial display for the cited sense; not asserted to be a verbatim source formula.

Concept: Alpha equivalence. No other notation record is assigned to this collision family.

NM-064. tensor product

Display: $\otimes$.

Local meaning. Tensor product with declared factor order and coordinate flattening. Distinct from ordinary matrix multiplication.

Domain and source. Chapter 19 (explanatory anchor `spectral-packet-tensor-and-operator-transport`); frozen reference-source Markdown lines 14168-14172.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Tensor coordinate transport. **Other senses in this notation family:** NM-065.

NM-065. composition

Display: $\circ$.

Local meaning. Composition uses the declared source and target types and execution order. Written path order and matrix order must be reconciled.

Domain and source. Chapter 9 (explanatory anchor `typed-operator-grammars`); frozen reference-source Markdown lines 3989-3995.

Spelling status. The exact display string occurs in the cited source chapter.

Concept: Operator word. **Other senses in this notation family:** NM-064.

NM-066. big O operation bound

Display: $O(\cdot)$.

Local meaning. An implementation cost model under stated arithmetic assumptions, not a measured runtime or total memory guarantee.

Domain and source. Chapter K (explanatory anchor `appendix-k-resource-budgets`); frozen reference-source Markdown lines 108137-108143.

Spelling status. Normalized editorial display for the cited sense; not asserted to be a verbatim source formula.

Concept: Memory estimate. No other notation record is assigned to this collision family.

M.6 Executable meaning checks

All 24 examples below executed against a separately installed copy of the pinned wheel. They use small finite fixtures with assertions active. Several intentionally reproduce a negative or permissive implementation boundary. A satisfied expectation is not a newly successful soundness, security, platform or theorem qualification.

GM-P01. Exactness does not imply a valid certificate

Concepts: Exactness, Certificate, Validity flag.

Observed result.

```
{
  "exactness": "exact",
  "refusal": "ValidationError"
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P02. Stored truthiness is not witness verification

Concepts: Validity flag, Certificate.

Observed result.

```
{
  "require_returned": true,
  "soundness_qualification": false,
  "stored_validity_type": "str"
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P03. General packets can be oblique

Concepts: Packet system, Orthogonal projector, Projector.

Observed result.

```
{
  "hilbert_valid": false,
  "packet_valid": true
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P04. Packet validation bypass remains visible

Concepts: Packet system, Orthogonal projector.

Observed result.

```
{
  "default_refuses": true,
  "repair_claim": false,
  "separate_hilbert_flag": true,
  "unchecked_packet_valid": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P05. Package frame operator is SA, not A* A

Concepts: Frame operator, Analysis-synthesis system.

Observed result.

```
{
  "analysis_gram": [
    [
      2.0,
      1.0
    ],
    [
      1.0,
      2.0
    ]
  ],
  "reconstruction": [
    [
      0.9999999999999996,
      1.6653345369377348e-16
    ],
    [
      5.551115123125783e-17,
      1.0
    ]
  ]
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P06. Coefficient projection is not the coefficient identity

Concepts: Coefficient projector, Synthesis map.

Observed result.

```
{
  "coefficient_dimension": 3,
  "full_coefficient_identity": false,
  "idempotent": true,
  "physical_dimension": 2
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P07. Gauge changes preserve the synthesized vector

Concepts: Coefficient gauge, Coordinate vector.

Observed result.

```
{
  "different_coefficients_same_physical_vector": true,
  "kernel_vector": [
    -1.0,
    -1.0,
    1.0
  ]
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P08. A reconstruction component need not be a projector

Concepts: Reconstruction component, Projector.

Observed result.

```
{
  "component": [
    [
      0.6666666666666663,
      0.0
    ],
    [
      -0.33333333333333326,
      0.0
    ]
  ],
  "components_reconstruct": true,
  "idempotent": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P09. Coordinate composition multiplies the following map on the left

Concepts: Coordinate transform, Operator word.

Observed result.

```
{
  "matrix": [
    [
      "1",
      "1"
    ],
    [
      "1",
      "2"
    ]
  ],
  "source": "A",
  "target": "C"
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P10. Transfer blocks use target then source

Concepts: Transfer block, Packet operator.

Observed result.

```
{
  "target_1_source_0": [
    [
      {
        "imag": 0.0,
        "real": 0.0
      },
      {
        "imag": 0.0,
        "real": 0.0
      }
    ],
    [
      {
        "imag": 0.0,
        "real": 3.0
      },
      {
        "imag": 0.0,
        "real": 0.0
      }
    ]
  ]
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P11. Stored normalized and monomial coefficients differ

Concepts: Normalized coefficient, Weighted monomial basis.

Observed result.

```
{
  "ordinary": [
    "1",
    "2",
    "3"
  ],
  "stored": [
    "1",
    "2",
    "6"
  ]
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P12. Exponential and ordinary products use different coefficient laws

Concepts: Hurwitz series, Convolution, Formal series.

Observed result.

```
{
  "exponential_stored": [
    "1",
    "2",
    "2"
  ],
  "ordinary_stored": [
    "1",
    "2",
    "1"
  ]
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P13. Nonzero need not mean unit in a composite residue ring

Concepts: Residue ring, Unit, Prime field.

Observed result.

```
{
  "inverse_two_mod_seven": 4,
  "two_is_unit_mod_six": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P14. Exact binary float conversion is not intended decimal rationalization

Concepts: Coercion, Exact arithmetic.

Observed result.

```
{
  "binary_exact_fraction": "3602879701896397/36028797018963968",
  "equal_one_tenth": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P15. Zero valuation follows the selected finite-domain convention

Concepts: Valuation, Truncated p-adic value.

Observed result.

```
{
  "valuation_27": 3,
  "valuation_zero": "infinity"
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P16. Residue lanes can have unequal lengths

Concepts: Lane, Residue coordinate.

Observed result.

```
{
  "channel_lengths": [
    3,
    2,
    2
  ],
  "reconstructed": true
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P17. Nested positional addressing is not CRT reconstruction

Concepts: Mixed-radix address, CRT coordinates.

Observed result.

```
{
  "CRT_residue": 1,
  "common_modulus": 6,
  "nested_address": 3
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P18. Typed exact identity has a finite matrix normal form

Concepts: Normal form, Basis witness, Typed expression.

Observed result.

```
{
  "certificate_valid": true,
  "normal_form": [
    [
      "1",
      "0"
    ],
    [
      "0",
      "1"
    ]
  ]
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P19. Portable loading preserves an invalid stored certificate

Concepts: Portable record, Certificate.

Observed result.

```
{
  "certificate_valid": false,
  "roundtrip_succeeded": true
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P20. Package and codec versions are different fields

Concepts: Codec, Migration, Package upgrade.

Observed result.

```
{
  "codec": 1,
  "package": "1.0.0b4",
  "tag": "python.fraction"
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P21. Adjoint is not transpose on complex data

Concepts: Adjoint, Orthogonal projector.

Observed result.

```
{
  "transpose_equals_adjoint": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P22. Stable facade identity is not an exactness claim

Concepts: Stable API, Alias.

Observed result.

```
{
  "finite_frame_exactness": "numerical",
  "identical_facade_class": true
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P23. A zero generator gives finite semigroup identity

Concepts: Matrix dynamics, Fundamental matrix.

Observed result.

```
{
  "dimension": 2,
  "finite_times": [
    0.2,
    0.3,
    0.5
  ],
  "infinite_model_claim": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

GM-P24. Object-array buffer size is not complete exact-object memory

Concepts: Memory estimate, Resource budget.

Observed result.

```
{
  "buffer_bytes": 16,
  "pointer_size": 8,
  "scalar_payload_in_nbytes": false
}
```

Expectation satisfied: yes. The exact executable function and its checked assertions are retained in `tools/block45/probes.py`. Runtime observations use tagged real/imaginary fields for complex numbers when necessary. These tags are only receipt formatting, not an additional portable mathematical codec.

M.7 Complete lexical formula concordance

`Block45_Math_Formula_Concordance.jsonl` contains **6,411 occurrence records** from the complete frozen glossary-source Markdown. Each record stores the exact delimited LaTeX span, byte-independent Python string offsets, 1-based source line range, enclosing heading and SHA-256 of the UTF-8 span. Repeated formulas remain separate occurrences so that different contexts are not collapsed.

The scanner excludes fenced code, inline backtick code and HTML comments, preserving their offsets as blanks. Its documented delimiters are backslash-parentheses, backslash-brackets, paired double dollars and single-line paired single dollars. This is a lexical concordance, not a full TeX parser, proof-term inventory or claim to recognize formulas without those delimiters. A table cell or historical planning equation is indexed when it satisfies the same rule. Individual bare variable mentions and code identifiers are outside this formula-spanning census.

For formula lookup, inspect the JSONL record's `start_line` and `end_line` in `Komorebi_Math_User_Guide_Block44_Appendix_L.md`. Do not apply those source offsets to a later edited edition. The index binds both reader-source and TeX checksums. The two smaller TSV files provide term and notation lookup without loading the full concordance.

M.8 Validation, regeneration and closure

The unchanged source suite passed **1,203 tests**. The installed glossary/reference suite passed **675 tests** and checked all source entries, links, collision groups, semantic examples and formula offsets/hashes. These counts overlap; the 24 semantic cases are also included in the reference suite. No count is a number of new mathematical theorems.

```
python tools/block45/inventory.py
python tools/block45/probes.py --output <fresh-replay-directory>
python tools/block45/run_reference_tests.py
python tools/block45/run_source_tests.py
python tools/block45/generate_manual.py
python tools/block45/build_pdfs.py
python VERIFY_BLOCK45_PACKAGE.py
```

Regenerate in a working copy. The reference runner checks that imported package bytes equal the pinned source and originate outside the checkout. Dependencies remain inherited, not freshly resolved in a dependency-isolated environment. Changing source, editorial data, index or receipts invalidates the corresponding evidence and requires new validation. A lookup-only use does not alter the artifacts.

Reference boundaries. The terminology catalog contains the stated 223 terms and 66 notation senses, together with its lexical concordance. These records do not repair certificate, portable-decoder, resource-limit, GPU or platform behavior. The recorded audit did not qualify Windows/PowerShell, other Python/dependency versions, CUDA, strict MkDocs, fully dependency-isolated installation, final publication or new Lean proofs. Appendix N provides the documentation-source crosswalk, and Appendix O identifies the separate final-source execution records.

Appendix N. Documentation-source crosswalk

The crosswalk is a reading and source-navigation contract for **Komorebi Math 1.0.0b4, Repair R2, wheel build 2**. It names every source in the configured documentation directory, identifies the current place to read its subject, preserves the historical role of older text, and records specific corrections without changing the pinned mathematical library.

Use the crosswalk when two documents seem to disagree. Find the file in N.3, read its status and resolution, then follow the listed destination. A "corrected" record also points to a specific explanation in N.4. This route lets you use an older document without guessing which of its statements still applies.

Read a record in this order: source path, reading status, destination, resolution, then source identity. The path tells you which text is being discussed; the status explains how to read it; the destination supplies the integrated explanation. The counts at the end help locate material within the source and need not be studied before following the reading route.

For example, the persistence source has explicit corrections for its envelope and migration keyword. Follow its correction records to Appendix G before adapting the old example. For a question about tests in the final source, go to Appendix O instead of treating an older documentation test count as a current execution result.

N.1 Coverage and source precedence

Surface	Recorded coverage
Markdown sources under configured docs directory	71
Additional repository-root Markdown sources	16
Unique source rows	87
Configured navigation entries / distinct targets	57 / 57
Site sources not in navigation	14
Explicit reviewed correction records	13
Export / module / command / example joins	1,526 / 300 / 46 / 65
Code blocks retained verbatim	301
Direct command-line occurrences	236
Lexical assertion candidates	716

The primary invariant is one and only one crosswalk row for each Markdown source below the configured `docs_dir`. This includes unlisted pages: navigation placement is not the document census. Sixteen repository-root Markdown files are an explicitly separate supplement. Release-directory reports, arbitrary third-party documents and all historical manual snapshots are not silently included as new primary rows.

Each record implements the retained design tuple: path, snapshot version, reading status, target anchors, source claims, commands, stale selectors and resolution. It additionally binds source lines, SHA-256, headings, link paths, imports and code blocks. Claims are **source assertion candidates**, recognized by a declared lexical rule. They are neither endorsed truth nor a theorem-to-proof relation. Test and verification attribution remains Appendix O (anchor `appendix-o-test-verification-crosswalk`).

Reading status	Meaning	Rows
current	Retained current policy or entry point; execution claims still need dated evidence	7
merged	Subject is integrated into the linked manual destinations	18
historical	Statements are scoped to the original named release or recorded event	45
superseded	Another pinned reference controls the present interface or workflow	4
corrected	Read with the explicit correction or precedence instruction in this crosswalk	13

Corrected is a reading instruction, not a claim that the retained source file was edited. Every R2 library byte is unchanged. The current R2 repair notice controls artifact selection, the source and manifests control interface identity, and current hash-bound execution records control local qualification. A historical positive count is not refreshed merely because the same file ships with a newer manual.

Line numbers identify a fixed source. Line-bound destinations refer to the frozen predecessor Markdown and LaTeX in the reference bundle. Page positions in the typeset book do not replace the recorded source offsets. Cumulative PDF references resolve to the current integrated chapters; the standalone volume names those destinations in the cumulative manual. Full source hashes are in the JSON; abbreviated hashes below are navigation aids, not complete integrity checks.

N.2 Navigation and implementation joins

All 57 configured navigation targets exist. The following 14 additional pages are indexed even though they are not listed in `mkdocs.yml`:

Unlisted source	Reading status
`docs/API_INVENTORY.md`	superseded
`docs/BLOCK_1_RELEASE.md`	historical
`docs/BLOCK_2_RELEASE.md`	historical
`docs/BLOCK_3_RELEASE.md`	historical
`docs/BLOCK_4_RELEASE.md`	historical
`docs/BLOCK_5_RELEASE.md`	historical
`docs/BLOCK_6_RELEASE.md`	historical
`docs/BLOCK_7_RELEASE.md`	historical
`docs/BLOCK_8_RELEASE.md`	historical
`docs/EXTENSION_API.md`	corrected
`docs/NINTH_MAJOR_BLOCK_REPORT.md`	historical
`docs/OPTIONAL_BACKEND_ISOLATION.md`	merged
`docs/POWERSHELL_TESTS.md`	superseded
`docs/STABLE_API.md`	superseded

Unlisted does not mean intentionally unpublished or unbuilt. That behavior belongs to the site generator. The recorded crosswalk audit did not run strict MkDocs and does not infer a production-site accessibility guarantee from this static inventory.

The API join retains all 131 stable, 83 beta and 1,312 research export records. Each export keeps its tier, public route, reported defining owner, source identity where package-owned, and its existing unique A-C anchor. The 300 module rows join package source files to Appendix D. The 46 command rows join handler sites to Appendix F, and the 65 example rows join script hashes to Appendix E. These joins are checked against actual separately installed objects and retained source, not guessed from matching display names.

Do not merge constants by their reflected type. A data export reported under `builtins.str`, `builtins.int` or another external type owner is still keyed by its public export route. Its reported owner does not mean the package constant was defined in that external module. Aliases, same-name concepts and data-type ownership are different relations. Lexical import matches provide navigation only and do not prove that a source page explains every behavior of that object.

N.3 Source record catalog

Every primary and supplemental source appears once below. Target references identify the authoritative reading destinations, not an assertion that every sentence was copied verbatim. Historical release cards keep their original chronology. Source assertion candidates and complete command lines are preserved electronically to avoid replacing them with an unsupported summary of proof coverage.

DN-001. `CHANGELOG.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Chapter 74 (anchor `block-21-publication-handoff`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Chronological changes are history. Each version heading scopes its statements; do not read every old current/count token as a present claim.

Source record: 396 lines; SHA-256 prefix `4d9e2ef5698cec59`. 81 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 5 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-002. `CONTRIBUTING.md`

Status: current. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 62 (anchor `chapter-62.-provenance-registries-and-extensions`), Chapter 74 (anchor `block-21-publication-handoff`), Chapter 82 (anchor `final-guide-publication-gate-and-retained-architecture`).

Resolution. Repository contribution policy is retained; no new public mutation or workflow execution is authorized by indexing it.

Source record: 26 lines; SHA-256 prefix `317c4476106460e2`. 1 lexical assertion candidate, 0 indexed command occurrences, 2 code blocks and 3 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-003. `LICENSE.md`

Status: current. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 74 (anchor `block-21-publication-handoff`), Chapter 82 (anchor `final-guide-publication-gate-and-retained-architecture`).

Resolution. License text is preserved verbatim and remains controlling. No legal interpretation or new license permission is supplied by this reference.

Source record: 7 lines; SHA-256 prefix `1a18635621db5832`. 0 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-004. `PACKAGE_AUDIT.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 73 (anchor `platform-and-release-qualification`), Chapter 74 (anchor `block-21-publication-handoff`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Recorded package-audit counts and test results are retained historical evidence, not the current source-suite totals.

Source record: 31 lines; SHA-256 prefix `c69a08734e1c90df`. 2 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-005. `README.md`

Status: corrected. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 2 (anchor `what-komorebi-math-is`), Chapter 3 (anchor `installation-and-environment-profiles`), Chapter 7 (anchor `public-api-tiers`), Appendix L (anchor `appendix-l-migrations`).

Resolution. The leading R2 repair banner controls artifact selection. Lower untagged wheel examples and alpha-era material remain historical.

Source record: 765 lines; SHA-256 prefix `4fbe47f0df7d9365`. 42 lexical assertion candidates, 62 indexed command occurrences, 38 code blocks and 75 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-13.

DN-006. `README_BLOCK16.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 20 (anchor `analysis-synthesis-and-redundant-frames`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Chapter 73 (anchor `platform-and-release-qualification`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retained block handoff describes that numbered revision. R2 repair instructions control the current artifact selection.

Source record: 46 lines; SHA-256 prefix `95c04507dfe6828c`. 2 lexical assertion candidates, 7 indexed command occurrences, 4 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-007. `README_BLOCK17.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Chapter 73 (anchor `platform-and-release-qualification`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retained block handoff describes that numbered revision. R2 repair instructions control the current artifact selection.

Source record: 172 lines; SHA-256 prefix `c500851084c3df4b`. 10 lexical assertion candidates, 12 indexed command occurrences, 15 code blocks and 5 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-008. `README_BLOCK18.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 20 (anchor `analysis-synthesis-and-redundant-frames`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retained block handoff describes that numbered revision. R2 repair instructions control the current artifact selection.

Source record: 32 lines; SHA-256 prefix `09105a93e5eea3e9`. 1 lexical assertion candidate, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-009. `README_BLOCK19.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 47 (anchor `measures-and-exact-polynomials`), Chapter 48 (anchor `integration-providers-and-quadrature`), Chapter 49 (anchor `integral-identities-and-coordinate-covectors`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retained block handoff describes that numbered revision. R2 repair instructions control the current artifact selection.

Source record: 38 lines; SHA-256 prefix `2d5bcb4762ebffe9`. 5 lexical assertion candidates, 2 indexed command occurrences, 2 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-010. `README_BLOCK20.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 50 (anchor `typed-finite-expression-model`), Chapter 51 (anchor `expression-evaluation-and-certification`), Chapter 52 (anchor `expression-planning-and-persistence`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retained block handoff describes that numbered revision. R2 repair instructions control the current artifact selection.

Source record: 84 lines; SHA-256 prefix `4ef56d3b562351a2`. 12 lexical assertion candidates, 0 indexed command occurrences, 1 code block and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-011. `README_BLOCK21.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 74 (anchor `block-21-publication-handoff`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retained block handoff describes that numbered revision. R2 repair instructions control the current artifact selection.

Source record: 36 lines; SHA-256 prefix `d7fd766f23b73f2b`. 1 lexical assertion candidate, 0 indexed command occurrences, 3 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-012. `RELEASE_REPAIR_R1.md`

Status: superseded. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 74 (anchor `block-21-publication-handoff`), Appendix L (anchor `appendix-l-migrations`).

Resolution. R1 is superseded by R2. Retain its diagnosis but do not install build 1 as the current artifact.

Source record: 28 lines; SHA-256 prefix `0f7e278a7f03bb29`. 4 lexical assertion candidates, 0 indexed command occurrences, 1 code block and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-013. `RELEASE_REPAIR_R2.md`

Status: current. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 74 (anchor `block-21-publication-handoff`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Authoritative retained repair identity and build-tag-2 artifact instructions. Old positive records do not qualify later platform executions.

Source record: 50 lines; SHA-256 prefix `811343fe6e7a2cd3`. 7 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-014. `REPRODUCIBILITY.md`

Status: current. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 70 (anchor `chapter-70.-export-and-reproducibility-recipes`), Chapter 74 (anchor `block-21-publication-handoff`), Chapter 81 (anchor `site-and-pdf-build-closure`).

Resolution. Reproducibility instructions are a workflow, not a claim that the crosswalk audit executed every gate. The package and platform boundaries remain explicit.

Source record: 59 lines; SHA-256 prefix `309431e1eb915086`. 4 lexical assertion candidates, 0 indexed command occurrences, 6 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-015. `SECURITY.md`

Status: current. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 61 (anchor `chapter-61.-portable-persistence`), Chapter 62 (anchor `chapter-62.-provenance-registries-and-extensions`), Appendix G (anchor `appendix-g-portable-schemas`), Appendix H (anchor `appendix-h-certificate-theorem-index`), Appendix I (anchor `appendix-i-exceptions-diagnostics`).

Resolution. Security-reporting policy is retained verbatim. This crosswalk neither hardens the reader nor changes disclosure permissions.

Source record: 17 lines; SHA-256 prefix `48dd3cbf84e6482e`. 2 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-016. `STATIC_AUDIT.md`

Status: historical. **Scope:** repository-prose. **Navigation:** not listed.

Destinations: Chapter 73 (anchor `platform-and-release-qualification`), Chapter 74 (anchor `block-21-publication-handoff`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Recorded static-audit results are historical. Hash-bound current checks govern the delivered snapshot.

Source record: 20 lines; SHA-256 prefix `85670e693e47cb79`. 0 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-017. `docs/ANALYSIS_SYNTHESIS_SYSTEMS.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 20 (anchor `analysis-synthesis-and-redundant-frames`), Appendix H (anchor `appendix-h-certificate-theorem-index`), Appendix M (anchor `appendix-m-glossary-notation`).

Resolution. Finite analysis/synthesis exposition is integrated in Chapter 20; H and M clarify the actual certificate and frame-operator conventions.

Source record: 88 lines; SHA-256 prefix `df2f841e733979a5`. 1 lexical assertion candidate, 0 indexed command occurrences, 4 code blocks and 4 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-018. `docs/API_COMPATIBILITY_0.10.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Version-bound structural policy is retained history. Current export, signature and semantic contracts are separately indexed.

Source record: 51 lines; SHA-256 prefix `5b59d694fb781bc6`. 3 lexical assertion candidates, 3 indexed command occurrences, 1 code block and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-019. `docs/API_COMPATIBILITY_0.11.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Version-bound structural policy is retained history. Current export, signature and semantic contracts are separately indexed.

Source record: 92 lines; SHA-256 prefix `7a5499d26b868372`. 5 lexical assertion candidates, 5 indexed command occurrences, 4 code blocks and 3 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-020. `docs/API_COMPATIBILITY_0.12.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Version-bound structural policy is retained history. Current export, signature and semantic contracts are separately indexed.

Source record: 24 lines; SHA-256 prefix `2e64f013a202d543`. 1 lexical assertion candidate, 2 indexed command occurrences, 2 code blocks and 4 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-021. `docs/API_COMPATIBILITY_0.13.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Version-bound structural policy is retained history. Current export, signature and semantic contracts are separately indexed.

Source record: 22 lines; SHA-256 prefix `7550dfac3da7fad6`. 1 lexical assertion candidate, 2 indexed command occurrences, 1 code block and 5 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-022. `docs/API_COMPATIBILITY_0.14.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Version-bound structural policy is retained history. Current export, signature and semantic contracts are separately indexed.

Source record: 9 lines; SHA-256 prefix `ccd29a6da86730ad`. 0 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 2 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-023. docs/API_COMPATIBILITY_0.15.md

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Version-bound structural policy is retained history. Current export, signature and semantic contracts are separately indexed.

Source record: 32 lines; SHA-256 prefix `80781528b1197af1`. 2 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 3 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-024. docs/API_INVENTORY.md

Status: superseded. **Scope:** mkdocs-source. **Navigation:** not listed.

Destinations: Appendix A (anchor `appendix-a.-stable-api-131-entry-frozen-reference`), Appendix B (anchor `appendix-b.-beta-api-83-entry-reference`), Appendix C (anchor `appendix-c.-research-api-1312-entry-reference`), Appendix D (anchor `appendix-d.-module-reference-ledger`).

Resolution. The thematic inventory is not the current exhaustive contract. Follow the source-bound 1,526 export records and module ledger.

Source record: 537 lines; SHA-256 prefix `344dcf267775330f`. 7 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 14 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-025. docs/API_STABILITY_REVIEW.md

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retain the explicitly historical review. Do not use its successor link to 0.10 as the latest API contract.

Source record: 90 lines; SHA-256 prefix `975dc242cd54254f`. 2 lexical assertion candidates, 0 indexed command occurrences, 2 code blocks and 3 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-026. docs/BEHAVIORAL_GOLDEN_AND_PROFILING.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 43 (anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix K (anchor `appendix-k-resource-budgets`).

Resolution. Closed behavioral fixtures and finite profiling are integrated. Sampling, traced allocation and complete process memory remain different measures.

Source record: 70 lines; SHA-256 prefix `4f66f14481d9df56`. 4 lexical assertion candidates, 0 indexed command occurrences, 3 code blocks and 2 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-027. docs/BETA_TO_RC.md

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 73 (anchor `platform-and-release-qualification`), Appendix J (anchor `appendix-j-backends-dependencies`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Retain the gate distinction; the sentence naming 1.0.0b1 is a historical example. Apply current evidence to the exact R2 artifact.

Source record: 30 lines; SHA-256 prefix `03630d50ccdbbd85`. 4 lexical assertion candidates, 2 indexed command occurrences, 3 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-11.

DN-028. `docs/BLOCK_10_RELEASE.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

DN-050. docs/BLOCK_9_RELEASE.md

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Chapter 38 (anchor `packet-jets-and-fauxe0-di-bruno-composition`), Chapter 39 (anchor `nonlinear-trees-and-graded-operations`), Chapter 40 (anchor `defects-obstruction-lifting-and-holonomy`), Chapter 41 (anchor `correction-and-elimination`), Chapter 42 (anchor `filtered-lifting-and-finite-spectral-sequences`), Chapter 44 (anchor `smooth-packet-transport`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Release-era scope and counts are retained history. Follow the current linked domain chapters and compatibility records.

Source record: 149 lines; SHA-256 prefix `674458831a50c29f`. 14 lexical assertion candidates, 0 indexed command occurrences, 2 code blocks and 7 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-051. docs/COMPANION_COORDINATE_CALCULUS.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 13 (anchor `residue-crt-lattice-and-smith-coordinates`), Chapter 15 (anchor `coordinate-objects`), Chapter 16 (anchor `exact-and-numerical-coordinate-transforms`), Chapter 17 (anchor `polynomial-and-classical-coordinate-families`), Chapter 18 (anchor `combinatorial-recurrence-and-state-space-coordinates`), Chapter 19 (anchor `spectral-packet-tensor-and-operator-transport`).

Resolution. Companion-derived finite coordinate examples have implementation-specific homes in Chapters 13 and 15-19. External companion claims are not re-proved by this crosswalk.

Source record: 13 lines; SHA-256 prefix `7e934e39ca92f3bc`. 1 lexical assertion candidate, 0 indexed command occurrences, 0 code blocks and 1 qualified lexical/import reference. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-052. docs/COMPANION_C_INTEGRATION.md

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 11 (anchor `packet-systems-and-transfer-blocks`), Chapter 14 (anchor `polyphase-systems-and-refinement`), Chapter 20 (anchor `analysis-synthesis-and-redundant-frames`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`).

Resolution. Retained reference-baseline adoption map, not a claim that every external Companion C construction is implemented or independently checked here.

Source record: 68 lines; SHA-256 prefix `f0966232553946c7`. 3 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-053. docs/DEPRECATION_POLICY.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Policy is integrated with actual decorator behavior. No removal schedule is inferred for unmarked retained aliases.

Source record: 45 lines; SHA-256 prefix `da3e4a5b82a7956a`. 1 lexical assertion candidate, 0 indexed command occurrences, 1 code block and 1 qualified lexical/import reference. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-054. docs/ELEVENTH_MAJOR_BLOCK_REPORT.md

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 43 (anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`), Chapter 61 (anchor `chapter-61.-portable-persistence`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Named development-block report is historical. Its implementation themes are integrated in the linked chapters; old execution counts are not current tests.

Source record: 134 lines; SHA-256 prefix `371687b2788b1e3e`. 16 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 1 qualified lexical/import reference. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-055. docs/EXPORT_AND_LATEX.md

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 59 (anchor `chapter-59.-mathematical-document-model`), Chapter 60 (anchor `chapter-60.-renderers-and-writers`), Chapter 70 (anchor `chapter-70.-export-and-reproducibility-recipes`), Appendix F (anchor `appendix-f-cli-option-matrix`), Appendix J (anchor `appendix-j-backends-dependencies`).

Resolution. Use F for command-specific overwrite behavior, including latex compile, and J for tool qualification. No common force flag is assumed across all paths.

Source record: 138 lines; SHA-256 prefix `cc509bc2df52d51b`. 3 lexical assertion candidates, 0 indexed command occurrences, 8 code blocks and 9 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-056. docs/EXTENSION_API.md

Status: corrected. **Scope:** mkdocs-source. **Navigation:** not listed.

Destinations: Chapter 62 (anchor `chapter-62.-provenance-registries-and-extensions`), Appendix I (anchor `appendix-i-exceptions-diagnostics`), Appendix J (anchor `appendix-j-backends-dependencies`).

Resolution. Extension entry points execute trusted Python in the caller. Catching ordinary exceptions is not child-process isolation or sandboxing; doctor discovers with activate=False.

Source record: 39 lines; SHA-256 prefix `6faa47f3b5232058`. 1 lexical assertion candidate, 1 indexed command occurrence, 3 code blocks and 2 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-08.

DN-057. docs/FINITE_MEASURE_INTEGRATION.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 47 (anchor `measures-and-exact-polynomials`), Chapter 48 (anchor `integration-providers-and-quadrature`), Chapter 49 (anchor `integral-identities-and-coordinate-covectors`), Chapter 68 (anchor `chapter-68.-integration-and-expression-recipes`).

Resolution. Finite exact measures, providers and covectors are integrated. Scope and quadrature error strength remain explicit.

Source record: 117 lines; SHA-256 prefix `7c33409a3174379f`. 18 lexical assertion candidates, 0 indexed command occurrences, 1 code block and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-058. docs/FOURTEENTH_MAJOR_BLOCK_REPORT.md

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 15 (anchor `coordinate-objects`), Chapter 16 (anchor `exact-and-numerical-coordinate-transforms`), Chapter 17 (anchor `polynomial-and-classical-coordinate-families`), Chapter 18 (anchor `combinatorial-recurrence-and-state-space-coordinates`), Chapter 19 (anchor `spectral-packet-tensor-and-operator-transport`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Named development-block report is historical. Its implementation themes are integrated in the linked chapters; old execution counts are not current tests.

Source record: 69 lines; SHA-256 prefix `a9879ab74341d78f`. 6 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-059. docs/GENERAL_COORDINATE_ATLAS.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 15 (anchor `coordinate-objects`), Chapter 16 (anchor `exact-and-numerical-coordinate-transforms`), Chapter 17 (anchor `polynomial-and-classical-coordinate-families`), Chapter 18 (anchor `combinatorial-recurrence-and-state-space-coordinates`), Chapter 19 (anchor `spectral-packet-tensor-and-operator-transport`), Chapter 64 (anchor `chapter-64.-exact-algebra-and-coordinate-recipes`).

Resolution. General finite coordinate atlas is integrated. Euler-Fibonacci is one case, not the namespace definition.

Source record: 257 lines; SHA-256 prefix `24990dd2b3a21622`. 14 lexical assertion candidates, 10 indexed command occurrences, 5 code blocks and 9 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-060. docs/GPU_INSTALLATION.md

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 3 (anchor `installation-and-environment-profiles`), Chapter 73 (anchor `platform-and-release-qualification`), Appendix J (anchor `appendix-j-backends-dependencies`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Treat the hardware stack as historical recorded context, not current R2 CUDA qualification. Replace the untagged b4 wheel path with the shipped build-2 artifact.

Source record: 30 lines; SHA-256 prefix `12df1bf3f72830e3`. 2 lexical assertion candidates, 0 indexed command occurrences, 3 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-09.

DN-061. `docs/GPU_VALIDATION.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 73 (anchor `platform-and-release-qualification`), Appendix J (anchor `appendix-j-backends-dependencies`).

Resolution. The file labels its Windows results as a recorded configuration. Do not transfer those results to the current CPU-only run or claim current CUDA success.

Source record: 48 lines; SHA-256 prefix `48d795cb61e10737`. 2 lexical assertion candidates, 1 indexed command occurrence, 2 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-062. `docs/IMPLEMENTATION_ROADMAP.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 0 (anchor `coverage-contract`), Chapter 74 (anchor `block-21-publication-handoff`), Chapter 82 (anchor `final-guide-publication-gate-and-retained-architecture`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Roadmap stages and future release objectives are retained plans, not evidence of a completed rc1 or 1.0.0 release.

Source record: 428 lines; SHA-256 prefix `4e1b7148c5364a16`. 55 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 4 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-063. `docs/LOCAL_VALIDATION.md`

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 3 (anchor `installation-and-environment-profiles`), Chapter 73 (anchor `platform-and-release-qualification`), Chapter 74 (anchor `block-21-publication-handoff`), Appendix F (anchor `appendix-f-cli-option-matrix`), Appendix J (anchor `appendix-j-backends-dependencies`), Appendix L (anchor `appendix-l-migrations`).

Resolution. The WindowsHotfix1 folder name is historical. Run the explicit current R2 launchers from the current checkout, and keep native-platform and MkDocs gates unclaimed here.

Source record: 62 lines; SHA-256 prefix `8a493de9655eecdf`. 6 lexical assertion candidates, 8 indexed command occurrences, 3 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-10.

DN-064. `docs/MIGRATION_TO_1_0.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Migration guidance is integrated with the full five-predecessor contract and actually tested finite forward upgrades.

Source record: 56 lines; SHA-256 prefix `4ea4cbb8f9d34609`. 0 lexical assertion candidates, 5 indexed command occurrences, 5 code blocks and 8 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-065. `docs/NINTH_MAJOR_BLOCK_REPORT.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** not listed.

Destinations: Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Chapter 38 (anchor `packet-jets-and-fauxe0-di-bruno-composition`), Chapter 39 (anchor `nonlinear-trees-and-graded-operations`), Chapter 40 (anchor `defects-obstruction-lifting-and-holonomy`), Chapter 41 (anchor `correction-and-elimination`), Chapter 42 (anchor `filtered-lifting-and-finite-spectral-sequences`), Chapter 44 (anchor `smooth-packet-transport`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Named development-block report is historical. Its implementation themes are integrated in the linked chapters; old execution counts are not current tests.

Source record: 116 lines; SHA-256 prefix `433c342f1f3584d9`. 6 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-066. `docs/NONLINEAR_CALCULUS.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Chapter 38 (anchor `packet-jets-and-fauxe0-di-bruno-composition`), Chapter 39 (anchor `nonlinear-trees-and-graded-operations`), Chapter 40 (anchor `defects-obstruction-lifting-and-holonomy`), Chapter 41 (anchor `correction-and-elimination`), Chapter 42 (anchor `filtered-lifting-and-finite-spectral-sequences`), Chapter 44 (anchor `smooth-packet-transport`).

Resolution. Higher nonlinear calculus is integrated with finite-dimensional and provider-specific boundaries preserved.

Source record: 133 lines; SHA-256 prefix `583f7a1daa3395ee`. 8 lexical assertion candidates, 0 indexed command occurrences, 9 code blocks and 3 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-067. `docs/NORMALIZED_GENERATING_FUNCTIONS.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 21 (anchor `formal-series-and-weighted-bases`), Chapter 22 (anchor `normalized-generating-functions`), Chapter 23 (anchor `masks-cartier-operators-and-digit-algebra`), Chapter 24 (anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`).

Resolution. Generating bases, transfer and arithmetic compilers are integrated. Use K for exact-scalar growth and local budget behavior.

Source record: 181 lines; SHA-256 prefix `9ae326da05e48905`. 12 lexical assertion candidates, 0 indexed command occurrences, 4 code blocks and 9 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-068. `docs/OPTIONAL_BACKEND_ISOLATION.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** not listed.

Destinations: Chapter 3 (anchor `installation-and-environment-profiles`), Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Appendix J (anchor `appendix-j-backends-dependencies`).

Resolution. The bounded child probes for optional autodiff are real and distinct from in-process extension discovery. Finite CPU evidence is not GPU qualification.

Source record: 47 lines; SHA-256 prefix `ba57434ff8161f3e`. 1 lexical assertion candidate, 0 indexed command occurrences, 2 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-069. `docs/PERSISTENCE_SCHEMAS.md`

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 61 (anchor `chapter-61.-portable-persistence`), Appendix G (anchor `appendix-g-portable-schemas`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Use the five-field envelope including producer_version and migrator=, not migrate=. The short codec list is partial and current permissive-reader limits are explicit in G.

Source record: 123 lines; SHA-256 prefix `6cc7466fc378ef99`. 4 lexical assertion candidates, 0 indexed command occurrences, 4 code blocks and 3 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-01, CN-02, CN-03, CN-04.

DN-070. docs/POWERSHELL_TESTS.md

Status: superseded. **Scope:** mkdocs-source. **Navigation:** not listed.

Destinations: Chapter 3 (anchor `installation-and-environment-profiles`), Chapter 70 (anchor `chapter-70.-export-and-reproducibility-recipes`), Chapter 74 (anchor `block-21-publication-handoff`), Appendix E (anchor `appendix-e-executable-example-records`), Appendix F (anchor `appendix-f-cli-option-matrix`), Appendix J (anchor `appendix-j-backends-dependencies`).

Resolution. The 0.11.0a1 installation recipe is historical. Use current build-2 installation instructions and E for pending native PowerShell execution.

Source record: 157 lines; SHA-256 prefix `983e529df7e9ad56`. 1 lexical assertion candidate, 26 indexed command occurrences, 13 code blocks and 1 qualified lexical/import reference. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-12.

DN-071. docs/PRODUCTION_SIGNAL_PROCESSING.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 31 (anchor `signal-conventions-windows-and-framing`), Chapter 32 (anchor `time-frequency-and-spectral-analysis`), Chapter 33 (anchor `filtering-and-convolution`), Chapter 34 (anchor `resampling-and-adaptive-filters`), Chapter 35 (anchor `filter-banks-wavelets-and-packet-trees`), Chapter 36 (anchor `singular-packets-and-recovery`), Chapter 66 (anchor `chapter-66.-signal-processing-recipes`).

Resolution. Production finite signal routines are integrated with transform normalization, framing and boundary conditions.

Source record: 346 lines; SHA-256 prefix `f395154c31b2bccc`. 16 lexical assertion candidates, 2 indexed command occurrences, 14 code blocks and 20 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-072. docs/PUBLIC_API.md

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Appendix A (anchor `appendix-a.-stable-api-131-entry-frozen-reference`), Appendix B (anchor `appendix-b.-beta-api-83-entry-reference`), Appendix C (anchor `appendix-c.-research-api-1312-entry-reference`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Use the complete A-C manifests. The historical sentence calling the whole package alpha is historical, not the current b4 release status.

Source record: 795 lines; SHA-256 prefix `0e87971221560e21`. 28 lexical assertion candidates, 29 indexed command occurrences, 34 code blocks and 110 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-07.

DN-073. docs/REDUNDANT_FRAME_ALGEBRA.md

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 20 (anchor `analysis-synthesis-and-redundant-frames`), Appendix M (anchor `appendix-m-glossary-notation`).

Resolution. Redundant coefficient-space algebra is integrated. Physical reconstruction components and coefficient projectors remain distinct.

Source record: 130 lines; SHA-256 prefix `429783554f95dd1b`. 4 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-074. `docs/RELEASE_PROCESS.md`

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 73 (anchor `platform-and-release-qualification`), Chapter 74 (anchor `block-21-publication-handoff`), Chapter 81 (anchor `site-and-pdf-build-closure`), Chapter 82 (anchor `final-guide-publication-gate-and-retained-architecture`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Read through the current R2 repair note. Build artifacts before qualification and use the build-2 wheel; a workflow declaration is not an executed hosted run.

Source record: 119 lines; SHA-256 prefix `996e47749965e57c`. 7 lexical assertion candidates, 0 indexed command occurrences, 4 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-075. `docs/RELEASE_QUALIFICATION.md`

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 73 (anchor `platform-and-release-qualification`), Chapter 74 (anchor `block-21-publication-handoff`), Appendix F (anchor `appendix-f-cli-option-matrix`), Appendix J (anchor `appendix-j-backends-dependencies`), Appendix L (anchor `appendix-l-migrations`).

Resolution. The current R2 launcher builds before qualification and binds installed-artifact checks. Native-platform and strict documentation gates remain separate from local source checks.

Source record: 63 lines; SHA-256 prefix `6019ab8d88c39c06`. 5 lexical assertion candidates, 8 indexed command occurrences, 5 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-076. `docs/SCALABLE_NONLINEAR_EXECUTION.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Chapter 38 (anchor `packet-jets-and-fauxe0-di-bruno-composition`), Chapter 43 (anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`), Appendix K (anchor `appendix-k-resource-budgets`).

Resolution. Finite plans, caches, snapshots and device paths are integrated. Check K for late guards and actual representation costs.

Source record: 146 lines; SHA-256 prefix `dc93a741e005ad74`. 5 lexical assertion candidates, 0 indexed command occurrences, 7 code blocks and 5 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-077. `docs/STABLE_API.md`

Status: superseded. **Scope:** mkdocs-source. **Navigation:** not listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Appendix A (anchor `appendix-a.-stable-api-131-entry-frozen-reference`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Use Appendix A for the frozen 131-name b4 stable surface. Candidate-era naming is retained history rather than a different current API.

Source record: 39 lines; SHA-256 prefix `23754cecb960a1f5`. 2 lexical assertion candidates, 2 indexed command occurrences, 2 code blocks and 5 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-078. `docs/STABLE_API_1_0_CANDIDATE.md`

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 7 (anchor `public-api-tiers`), Appendix A (anchor `appendix-a.-stable-api-131-entry-frozen-reference`), Appendix B (anchor `appendix-b.-beta-api-83-entry-reference`), Appendix C (anchor `appendix-c.-research-api-1312-entry-reference`), Appendix L (anchor `appendix-l-migrations`).

Resolution. The 1,179 research-name count is historical. The pinned research manifest now has 1,312 records; stable remains 131 and beta remains 83.

Source record: 98 lines; SHA-256 prefix `f815eae16d91bcec`. 4 lexical assertion candidates, 3 indexed command occurrences, 2 code blocks and 12 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-06.

DN-079. `docs/STREAMING_PACKET_JETS.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 43 (anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`), Chapter 61 (anchor `chapter-61.-portable-persistence`), Appendix G (anchor `appendix-g-portable-schemas`), Appendix K (anchor `appendix-k-resource-budgets`).

Resolution. Chunked stream and resumability records are integrated. Partial evaluation does not imply a complete materialized snapshot.

Source record: 168 lines; SHA-256 prefix `02cb2fe400a6dfb8`. 7 lexical assertion candidates, 2 indexed command occurrences, 7 code blocks and 4 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-080. `docs/SUPPORTED_PLATFORMS.md`

Status: current. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 3 (anchor `installation-and-environment-profiles`), Chapter 8 (anchor `backends-scalar-domains-and-coercion`), Chapter 73 (anchor `platform-and-release-qualification`), Appendix J (anchor `appendix-j-backends-dependencies`).

Resolution. Declared Python/dependency support is explicitly distinct from recorded execution. No new platform support is inferred from this crosswalk.

Source record: 25 lines; SHA-256 prefix `ca089e55c98cb10a`. 2 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-081. `docs/TENTH_MAJOR_BLOCK_REPORT.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 37 (anchor `derivative-providers-and-automatic-differentiation`), Chapter 38 (anchor `packet-jets-and-fauxe0-di-bruno-composition`), Chapter 43 (anchor `nonlinear-execution-streaming-profiling-and-gpu-paths`), Chapter 61 (anchor `chapter-61.-portable-persistence`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Named development-block report is historical. Its implementation themes are integrated in the linked chapters; old execution counts are not current tests.

Source record: 131 lines; SHA-256 prefix `4c20dcb814d2b497`. 9 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-082. `docs/THIRTEENTH_MAJOR_BLOCK_REPORT.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 21 (anchor `formal-series-and-weighted-bases`), Chapter 22 (anchor `normalized-generating-functions`), Chapter 23 (anchor `masks-cartier-operators-and-digit-algebra`), Chapter 24 (anchor `prime-power-bell-cyclotomic-and-q-kummer-systems`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Named development-block report is historical. Its implementation themes are integrated in the linked chapters; old execution counts are not current tests.

Source record: 68 lines; SHA-256 prefix `c62c83149a73659f`. 7 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-083. `docs/TWELFTH_MAJOR_BLOCK_REPORT.md`

Status: historical. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 31 (anchor `signal-conventions-windows-and-framing`), Chapter 32 (anchor `time-frequency-and-spectral-analysis`), Chapter 33 (anchor `filtering-and-convolution`), Chapter 34 (anchor `resampling-and-adaptive-filters`), Chapter 35 (anchor `filter-banks-wavelets-and-packet-trees`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Named development-block report is historical. Its implementation themes are integrated in the linked chapters; old execution counts are not current tests.

Source record: 87 lines; SHA-256 prefix `fd44fa290ed58b0f`. 5 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-084. `docs/TYPED_FINITE_EXPRESSION_CALCULUS.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 50 (anchor `typed-finite-expression-model`), Chapter 51 (anchor `expression-evaluation-and-certification`), Chapter 52 (anchor `expression-planning-and-persistence`), Chapter 68 (anchor `chapter-68.-integration-and-expression-recipes`).

Resolution. Finite rational typed language is integrated. The normal-form equality statement stays within its declared finite domain.

Source record: 320 lines; SHA-256 prefix `8c47d1cb4d09d88f`. 32 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-085. `docs/UNIFIED_LANGUAGE.md`

Status: merged. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 2 (anchor `what-komorebi-math-is`), Chapter 9 (anchor `typed-operator-grammars`), Chapter 11 (anchor `packet-systems-and-transfer-blocks`), Chapter 28 (anchor `packet-intermediate-representation`), Chapter 50 (anchor `typed-finite-expression-model`).

Resolution. Unified language is an organizing interface across finite domains, not an assertion that every planned completion exists.

Source record: 277 lines; SHA-256 prefix `1dcf70b9988707b7`. 21 lexical assertion candidates, 0 indexed command occurrences, 16 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

DN-086. `docs/UPGRADE_CONTRACT.md`

Status: corrected. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 72 (anchor `api-semantic-persistence-and-upgrade-contracts`), Appendix L (anchor `appendix-l-migrations`).

Resolution. Two listed alpha predecessors and the b1 target are historical. The current contract covers five predecessor wheels and the b4 reader.

Source record: 33 lines; SHA-256 prefix `4c2b76e06be9196d`. 3 lexical assertion candidates, 0 indexed command occurrences, 1 code block and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

Specific corrections: CN-05.

DN-087. `docs/index.md`

Status: current. **Scope:** mkdocs-source. **Navigation:** listed.

Destinations: Chapter 2 (anchor `what-komorebi-math-is`), Chapter 7 (anchor `public-api-tiers`), Chapter 74 (anchor `block-21-publication-handoff`).

Resolution. Current site landing page. Read the R2 repair note before selecting an installable artifact.

Source record: 50 lines; SHA-256 prefix `f1732465c164d55c`. 4 lexical assertion candidates, 0 indexed command occurrences, 0 code blocks and 0 qualified lexical/import references. These counts are navigation metadata, not new tests or semantic completeness claims.

N.4 Concrete correction and precedence records

The following selectors locate the exact retained text. A source file may have more than one correction. Conversely, a reading-status correction can be a workflow precedence rule rather than a single obsolete token. A literal version-shaped string is not automatically stale: older releases, dependency versions and numeric examples can all legitimately occur in current prose.

CN-01. `PERSISTENCE_SCHEMAS.md`

Retained source: `komorebi-math/docs/PERSISTENCE_SCHEMAS.md`, line 16. **Exact selector:** `"schema_version": 1`.

Resolution. The displayed four-field envelope omits required producer_version. Use dumps_portable and preserve all five envelope fields. Read Appendix G (anchor `appendix-g-portable-schemas`).

CN-02. `PERSISTENCE_SCHEMAS.md`

Retained source: `komorebi-math/docs/PERSISTENCE_SCHEMAS.md`, line 84. **Exact selector:** `migrate=lambda`.

Resolution. register_portable_migration accepts migrator=; migrate= raises TypeError. The corrected custom registration is executed in the recorded correction probe. Read Appendix G (anchor `appendix-g-portable-schemas`).

CN-03. `PERSISTENCE_SCHEMAS.md`

Retained source: `komorebi-math/docs/PERSISTENCE_SCHEMAS.md`, line 58. **Exact selector:** `The current registry includes codecs for:.`

Resolution. This is a partial early list, not an exhaustive current registry. The pinned registry has 51 mathematical codecs. Read Appendix G (anchor `appendix-g-portable-schemas`).

CN-04. PERSISTENCE_SCHEMAS.md

Retained source: komorebi-math/docs/PERSISTENCE_SCHEMAS.md, line 54. **Exact selector:** `The decoder validates dimensions and recursion depth before reconstruction.`.

Resolution. Do not infer strict universal types or hostile-input resource safety from this sentence. G records permissive conversions and parsing before the depth guard. Read Appendix G (anchor `appendix-g-portable-schemas`).

CN-05. UPGRADE_CONTRACT.md

Retained source: komorebi-math/docs/UPGRADE_CONTRACT.md, line 8. **Exact selector:** `0.15.0a2`.

Resolution. The two-entry predecessor listing is incomplete for the current five-predecessor contract. No downgrade or all-object migration guarantee follows. Read Appendix L (anchor `appendix-l-migrations`).

CN-06. STABLE_API_1_0_CANDIDATE.md

Retained source: komorebi-math/docs/STABLE_API_1_0_CANDIDATE.md, line 83. **Exact selector:** `1,179`.

Resolution. The research count is 1,312 in the pinned manifests. Stable 131 and beta 83 are different tier inventories. Read Appendix C (anchor `appendix-c.-research-api-1312-entry-reference`).

CN-07. PUBLIC_API.md

Retained source: komorebi-math/docs/PUBLIC_API.md, line 735. **Exact selector:** `The complete package remains alpha.`.

Resolution. This sentence belongs to the historical source baseline. The actual pinned package version is 1.0.0b4, Repair R2 build 2. Read Appendix L (anchor `appendix-l-migrations`).

CN-08. EXTENSION_API.md

Retained source: komorebi-math/docs/EXTENSION_API.md, line 37. **Exact selector:** `loads each extension in isolation.`

Resolution. Discovery uses point.load and any callable factory in the same interpreter; ordinary Exception handling is not a subprocess boundary. doctor does not request activation. Read Appendix J (anchor `appendix-j-backends-dependencies`).

CN-09. GPU_INSTALLATION.md

Retained source: komorebi-math/docs/GPU_INSTALLATION.md, line 13. **Exact selector:** `komorebi_math-1.0.0b4-py3-none-any.whl`.

Resolution. The retained untagged filename is not the shipped R2 artifact. Use komorebi_math-1.0.0b4-2-py3-none-any.whl and verify its hash. Read Appendix L (anchor `appendix-l-migrations`).

CN-10. LOCAL_VALIDATION.md

Retained source: komorebi-math/docs/LOCAL_VALIDATION.md, line 13. **Exact selector:** `Block21_WindowsHotfix1`.

Resolution. This folder name is historical. Current launchers must run from the current R2 checkout; an old folder name is not release identity. Read Appendix L (anchor `appendix-l-migrations`).

CN-11. BETA_TO_RC.md

Retained source: komorebi-math/docs/BETA_TO_RC.md, line 26. **Exact selector:** `For 1.0.0b1`.

Resolution. This is a historical beta example. Current platform acceptance must be tied to the exact current build and evidence. Read Appendix J (anchor `appendix-j-backends-dependencies`).

CN-12. POWERSHELL_TESTS.md

Retained source: komorebi-math/docs/POWERSHELL_TESTS.md, line 6. **Exact selector:** komorebi_math-0.11.0a1-py3-none-any.whl.

Resolution. Old PowerShell install recipe is superseded for this delivery. Native current PowerShell replay remains pending, not certified by Linux execution. Read Appendix E (anchor appendix-e-executable-example-records).

CN-13. README.md

Retained source: komorebi-math/README.md, line 43. **Exact selector:** komorebi_math-1.0.0b4-py3-none-any.whl.

Resolution. Follow the leading R2 repair notice over the lower inherited untagged wheel example. Build 2 is the retained current artifact. Read Appendix L (anchor appendix-l-migrations).

Extension isolation is especially easy to misread. The pinned implementation calls point.load() and a callable factory in the same Python interpreter. It catches ordinary Exception and stores a failure record, but SystemExit propagates. Discovery defaults to activate=False; that does not prevent import-time or factory code from running. Two controlled synthetic-entry-point probes confirm this behavior. They do not install an external plugin, simulate a native abort or qualify a sandbox.

N.5 Links, snippets and command interpretation

Static observation	Result
CommonMark link occurrences	75
Ordinary local file links resolving to retained paths	74
Math-markup link candidates with no matching file	1
Direct command lines recognized in the current command census	236
Argument-parser acceptance in the recorded normalization profile	236 / 236
Indexed Python code-block syntax	All Python-tagged blocks parse; this is not execution

The one ambiguous link is in docs/NORMALIZED_GENERATING_FUNCTIONS.md: the local-mask formula containing R](z) is parsed as a link to z by the CommonMark inventory parser. No docs/z exists. The source location and parser interpretation remain visible in the ledger; the record is not discarded to report zero unresolved links. A mathematics-aware site build should establish its actual rendering. **No strict MkDocs result is claimed**, and the CommonMark observation is not presented as a tested MkDocs failure.

Only file paths are checked here. Markdown fragments are retained but not resolved through an actual MkDocs renderer; external URLs are not fetched. Manual destination anchors are a separate relation and are checked for uniqueness in the pinned TeX. Heading line numbers and source fragments are bound to checksums, so an old anchor cannot silently be applied to changed prose.

The code-block inventory retains 301 fenced or indented blocks with language labels and exact source spans. Python-tagged blocks are parsed syntactically without execution. The CLI scanner recognizes direct komorebi, python -m komorebi_math and & $Komorebi lines inside these blocks. It does not expand arbitrary shell variables, execute installations, run compound shell programs or infer commands from un-delimited prose.

The 236 parser observations normalize quoting with the declared local tokenization profile and invoke only build_parser().parse_args. **No command handler is executed by this replay.** Valid option spelling does not establish that an input file exists, a mathematical assumption holds, a backend works or the command returns a positive qualification. For real finite command execution, use the retained evidence in Appendix F (anchor appendix-f-cli-option-matrix) and its explicit platform limits.

N.6 Executable correction observations and lookup

Executed check	Recorded result
Unchanged full source suite	1,203 passed
Reference/source/anchor/identity suite	2357 passed
Finite correction probes	8 / 8 expectations satisfied
Actual lookup CLI scenarios	8 / 8 expectations satisfied
Source-to-installed-package byte parity	366 / 366
Argument-parser observations	236 accepted, zero handlers executed

ND-P01. Reflect stable, beta and research inventories as 131, 83 and 1,312 records.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P02. Load a genuine five-field portable envelope and reject the same envelope after removing producer_version.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P03. Reject migrate=, register the correct migrator= callable, and apply it to one finite dictionary.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P04. Count the actual installed registry as 51 mathematical codecs, not the short early prose list.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P05. Observe synthetic entry-point loading and factory execution in the caller PID; distinguish default discovery from explicit activation.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P06. Record an ordinary extension exception and observe that a controlled SystemExit propagates.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P07. Find the shipped build-2 wheel and confirm the inherited untagged current-wheel path is absent.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

ND-P08. Read the actual predecessor_versions contract field and verify its five declared versions.

Observed expectation: satisfied. Full output and input hashes are in `correction_probe_execution.json`. This is a finite implementation observation, not a new theorem or universal migration guarantee.

The actual lookup tool validates source bindings before answering. Examples, from the delivery root:

```
python tools/block46/lookup.py \
  --source docs/PERSISTENCE_SCHEMAS.md --unique
python tools/block46/lookup.py --target G
python tools/block46/lookup.py \
  --symbol komorebi_math.PacketSystem --unique
```

The eight command scenarios include a single-source lookup, a target reverse lookup, an exact API-route lookup, a deliberately ambiguous historical-name query, no-match and incompatible-filter refusals, the current repair note, and a source omitted from navigation. Exit 0 means matches, 1 means no match, 2 means strict uniqueness was not satisfied, and 3 means validation found stale inputs. The tool does not silently select one of several historical matches.

N.7 Reconstruction, boundaries and next work

`inventory.py` regenerates the JSON crosswalk, source lookup TSV and complete code-block JSONL. `generate_manual.py` reconstructs both Markdown and both LaTeX sources. `reproduce_sources.py` checks all seven outputs in a separate temporary working tree. `validate.py` rejects missing rows, changed source bytes, ambiguous manual anchors and unreviewed non-mathematical link failures. Build and delivery tools independently bind test logs, content digests and reviewed PDF bytes.

The eight correction probes, 236 parser observations and 2357 reference tests overlap in scope. They must not be summed as independent mathematical proofs. The eight actual lookup processes do not execute the mathematical commands being described. All installed-package observations use a separate build-2 installation with inherited host dependencies, not a successful fully dependency-isolated environment.

Reference boundaries. This crosswalk covers the configured documentation-source census and the stated API, module, command and example joins. The recorded audit did not qualify native Windows/PowerShell, other Python/dependency versions, CUDA, strict MkDocs, fully dependency-isolated installation, final publication or new Lean proofs. Certificate, portable-reader and resource-budget limitations remain separate. Appendix O supplies the final source's static test and verification crosswalk and identifies its retained execution evidence.

Appendix O. Test and verification crosswalk

Use this appendix to find the relevant tests. Search for a module, function or class name, then open the matching source record. O.4 lists test modules, O.5 installed verification modules, and O.6 repository verification programs. O.3 identifies the retained execution reports when you need to know what was actually run.

Read one card in three steps. First check its source path and pinned revision. Next use its import targets to locate the code under examination. Finally read the linked test or verification program to see its setup, input values and assertions. Those details tell you whether it exercises the case you care about. A file with no literal Komorebi import may still reach the library through a helper or subprocess, so inspect its entry point before ruling it out.

Keep two questions separate as you navigate: “Where is this behavior checked?” and “Which run demonstrated it in my intended environment?” The index helps answer the first; the source and execution receipt together answer the second. If you add a regression case, retain the command, selected tests, environment and actual result alongside the source revision, so the next reader can follow the same route.

O.1 Scope and interpretation

This crosswalk identifies the test modules and verification programs in the final Python source. It connects each file to literal Python import statements and records its syntactic test definitions, assertions and source locations. These are navigation records. An import does not establish that every imported object was called, that a branch was exercised, or that a mathematical claim was proved.

The inventory is produced by parsing Python source with `ast`. It does not import the package, run pytest collection, expand parametrized cases, execute a verification program, or measure statement or branch coverage. A function whose name begins with `test_` is counted as a syntactic definition, including nested definitions. Its presence does not guarantee that pytest collects or executes it. Conditional imports are retained even when their branch might not execute. Imports made through runtime strings and attribute access through a package alias are not resolved into an invented call graph.

The complete JSON record retains every import name, alias and source line, all test-definition names and line ranges, top-level function names, per-file SHA-256 digests and the bound evidence receipts. Printed cards list literal Komorebi import targets. Files without such an import can still exercise the package through a subprocess, helper or dynamic route; inspect their source and execution evidence.

O.2 Frozen source identity

The source commit is `5f2b7ddc879c12d2bb00cbe5c487aa0bc7709222` and its repository tree is `7c9b4caee01fdc0bb64149e27ce46926241e21f2`. This current-source inventory is distinct from the recorded predecessor observations in Appendices A through N. The original test and diagnostic identifiers in those appendices remain locators for their stated source baseline.

The canonical path-and-SHA-256 manifest for these 328 files has digest `f19784e2b48a750161d9a3cc7576af477f5f58dc6747d9b5dd384cb099ed7d6e`. The full structured record inventory has digest `4bf60c79f3ab92132d5e1933f76cffaa68e8d1cf84fcebb153dcb08c3edd18b0`. Both digests use UTF-8 JSON with sorted keys and compact separators. The machine-readable inventory and the generator accompany the editable manual.

Source set	Files	Syntactic test definitions
Test modules	194	1655
Installed verification modules	28	0
Repository verification programs	106	0

These definition counts are not expected to equal a pytest result count. Parametrization can produce several runtime cases from one function, while selection rules can exclude a definition. Verification programs also contain helpers and entry points that are not pytest tests.

O.3 Recorded execution evidence

The retained release status records **2,752 passing source tests with seven optional-backend skips**. A separate CPU campaign records all seven of those cases passing, with no failures, errors or skips. Its input-binding receipt confirms that the campaign inputs match the final source; its source-parity receipt records only workflow-file differences outside that campaign. The installed direct wheel and the wheel rebuilt from the source distribution each record 1,556 passing tests. These reports predate this editorial pass and were not rerun to generate the crosswalk.

The release records also retain 84 executable documentation examples, 351 base stress checks and 11 resource controls. These groups overlap and must not be added together as independent mathematical proofs. This appendix does not promote a successful finite test into a Lean proof or an unbounded theorem.

Fresh hosted Linux/Windows qualification did not start because the provider reported an account payment or spending-limit restriction. Real NVIDIA qualification and a qualified tagged release-candidate predecessor remain publication prerequisites in the retained status. A prepared distribution and a configured workflow are not completed publication or hardware qualification.

O.7 Reproduction and limits

Run the bundled `build_test_crosswalk.py` against the frozen repository source and the retained release-evidence directory. The generator writes the JSON inventory and this appendix from the same parsed records. A source-file change changes the manifest binding even when its printed test count stays the same. The generator intentionally performs no package import or test execution.

For a dynamic coverage claim, run the chosen test selection with an explicitly configured coverage tool, retain the exact source and environment, and distinguish statement, branch and mathematical-condition coverage. For a new qualification claim, retain its actual execution receipt. The static relationships printed here provide routes to inspection and reproduction; they do not substitute for either measurement.

Part XIV. Documentation standards and design specifications

How to use this reference part. Chapters 75 through 82 describe the standards for maintaining a reliable manual and its supporting records. Chapters 83 through 88 collect detailed design specifications for the earlier mathematical and computational chapters. These are useful to contributors, implementers, and readers checking a precise contract. They are not prerequisites for using the library.

Start with the explanatory chapter when learning a feature. Use its API card for the import, signature, accepted inputs, and result. Consult the matching specification here when you need the compact list of equations, hypotheses, edge cases, and example obligations. Where a specification identifies its explanatory chapter as authoritative, read that chapter's more detailed qualification before applying the compact statement.

Several terms recur in this part. A *gate* is a named acceptance check. A *ledger* is a structured inventory with evidence or status attached to each item. A *fixture* is a committed input and expected result used for a repeatable check. *Closure* means that the stated inventory has been accounted for under its stated rule. None of these terms enlarges the mathematical scope of a calculation.

Requirements and observations have different roles. An example checklist says what a complete example should demonstrate. A recorded result says what a specified run actually demonstrated. A target completion predicate states the conditions to be met; it does not assert that every condition has been met. Historical inventories and release observations retain their declared source baseline. Use the current package records for a new release decision.

75. Freeze and finalization protocol

The production freeze converts a moving source tree into a reviewable documentation snapshot. It freezes **evidence identity**, not future project development. A later release may add symbols, examples, or workflows, but it must do so under a new versioned inventory instead of changing the meaning of the declared reference baseline.

75.1 What is frozen

A usable freeze record has four layers:

$$F = (v, \mathcal{I}, h, \mathcal{R}),$$

where v is the package and handoff identity, $\mathcal{I}$ is the measured inventory, h is the set of content digests, and $\mathcal{R}$ records open reconciliation items. A count without the files that produced it is not a freeze, and a digest without a semantic inventory is not a coverage claim.

The reference source snapshot resolves to these measured sets.

Source surface	Frozen observation
Stable API	131 exports: 58 classes, 61 functions, 12 data symbols
Beta API	83 exports: 45 classes, 28 functions, 10 data symbols
Research API	1,312 exports: 518 classes, 733 functions, 61 data symbols. All 1,312 symbol cards are complete: 516 root and the complete coordinate, generating, signal, nonlinear, and export namespaces
Research implementation-owner strings	201: 196 package owners and 5 standard-library owners
Python implementation modules	300
Shipped examples	65: 57 Python and 8 PowerShell
Root workflow wrappers	42: 21 PowerShell and 21 POSIX shell
CLI leaf commands	46
Installed verification-suite names	51
Verification modules	50
Test inventory	130 by guide convention: 129 `test_*.py` modules plus `optional_backend_support.py`
Frozen portable codecs	51 codecs and one adjacent migration
Export formats	11
Documentation Markdown files	71: 57 in MkDocs navigation and 14 outside it

The five standard-library implementation owners are `builtins`, `collections.abc`, `pathlib`, `types`, and `typing`. They are reflected owners, not five missing package modules. Likewise, the 201 research owner strings are not interchangeable with the 300 Python source modules. Keeping those meanings separate prevents a numerically plausible but semantically false reconciliation.

The canonical JSON digests bind the three public manifests:

Manifest	Canonical SHA-256
Stable	`23cd9e47a1663f2d4b3c0fef50f9f7d8c88d4af2f8bbc57e7ba76461e6e69276`
Beta	`311f2bf7cbcf0a45bcbe2af433d73a8f597c0fbf7133750882314d6e0edb16b2`
Research	`473c73e1a0563fe0b2569c8be384f7c9f947570bea2f300ef611db351136847a`

Manifest	Canonical SHA-256

Canonical JSON means UTF-8 JSON serialized with sorted keys and compact separators. A raw-file checksum is also useful, but it changes when formatting changes. A canonical digest binds the decoded contract.

75.2 Source precedence

Source precedence is claim-specific. Export names, kinds, owners, and signatures come from live reflection reconciled with the committed manifest. Stable summaries come from `stable_documentation_1_0.json` and its release loader. Mathematical meaning comes from implementation, frozen semantic cases, and tests. Persistence claims come from the 51-codec contract and its one adjacent migration. Example existence comes from the filesystem. Execution claims require a fresh result tied to an environment and source digest. The cumulative Markdown is the reader source for this manual, while the repository MkDocs corpus is a separate companion site source.

These commands inspect the current public contracts:

```
python -m komorebi_math api check --strict-signatures
python -m komorebi_math api check --beta
python -m komorebi_math api check --stable
python -m komorebi_math verify stable
python -m komorebi_math release documentation
python -m komorebi_math release contract
```

The stable verifier additionally requires exact committed-snapshot equality. An isolated additive-compatibility comparison may tolerate a new name, but the frozen stable snapshot does not accept an uncommitted addition.

75.3 Alias and identity rules

The canonicalization map from Chapter 0 remains the governing rule. Classes and functions join by defining module and qualified name. Data exports remain keyed by exported namespace and name unless the source explicitly declares an alias. That distinction prevents equal or interned constants from being collapsed.

Under this rule the 1,312 research exports form 1,092 canonical identities: a 220-entry alias surplus distributed across 207 multi-export groups. These numbers help detect drift. They do **not** reduce the obligation to give every exported name a searchable path. The stable tier similarly has 131 names across each of the three versioned facades, for 393 name-preserving routes, while Appendix A intentionally retains one anchor per stable exported name.

Five deliberate cross-name stable pairs receive explicit links: `CoordinateTransform` / `ExactCoordinateTransform`, `refine_polyphase` / `polyphase_refine`, `coarsen_polyphase` / `polyphase_coarsen`, `refine_lattice_polyphase` / `lattice_polyphase_refine`, and `coarsen_lattice_polyphase` / `lattice_polyphase_coarsen`. Root or domain re-export alone does not grant stable status.

The final ledger therefore stores both maps:

$$\text{exported name} \longrightarrow \text{canonical identity}, \qquad \text{canonical identity} \longrightarrow \text{all public routes}.$$

75.4 Freeze procedure

Use this order so that prose never becomes the source of truth for an inventory.

1. Record the exact repository, package version, and release-contract identity.
2. Parse the committed API, codec, CLI, verification, documentation, and release inventories directly from source.
3. Apply the alias rule above and retain every exported route.
4. Compare observed counts and canonical digests with the prior checkpoint.
5. Classify each difference as an intended source change, a documentation correction, historical evidence, or an unresolved inconsistency.

6. Freeze only after every difference has an owner and disposition. An open disposition may remain, but it must remain visible.

Before describing a domain as complete, identify its source set, required records, and unresolved items. Prose cannot substitute for missing evidence.

75.5 Recorded freeze result

The stable manifest and all 131 Appendix A cards reconcile exactly. The beta manifest and all 83 Appendix B cards also reconcile exactly, including signatures, anchors, aliases, and strict compatibility. Appendix C reconciles all 1,312 research cards with four derived indexes built from the same source set.

C.7 accounts for all 201 research implementation owners. C.8 covers all 1,093 distinct research names and all 1,312 research namespace and name pairs. C.9 covers all 923 exact research signature values. C.10 assigns all 1,526 stable, beta, and research card routes to one route-identity and stability group each. Same-spelling functions that resolve to different objects remain separate.

The reference-baseline negative controls below retain their declared failure outcomes. They illustrate that reference coverage and platform qualification are separate predicates:

```
python -m komorebi_math release evidence --current
python -m komorebi_math release readiness --final
```

The failure records concern the declared reference baseline. They do not determine the readiness of another package version or platform.

> **Chapter 75 boundary.** A freeze binds source identity, precedence, inventories, canonicalization rules, and reconciliation decisions. It does not establish unexecuted platform or publication claims.

76. Symbol-card completion contract

A symbol card is the smallest independently reviewable API explanation. It must let a reader identify the exported object, decide whether it applies, predict its result and failures, choose dependencies and resources, and reach the evidence that supports the claim. A signature and a one-line summary alone are an index entry, not a complete card.

76.1 Card anatomy

For exported record s, define

$$\mathrm{Card}(s) = \{id, q, a, t, k, s, D, C, H, R, X, E, P, B, K, V, L\}.$$

Field	Required meaning
`id`	exported namespace and name
`q`	canonical implementation identity
`a`	aliases and supported import routes
`t`	stability tier and version
`k`	manifest kind
`s`	exact manifest signature, including literal `null`
`D`	mathematical or operational definition
`C`	domain, codomain, types, shapes, and units
`H`	hypotheses and preconditions
`R`	return contract and result variants
`X`	exceptions, diagnostics, and invalid inputs
`E`	exactness, tolerance, and determinism class
`P`	dependency and platform profile
`B`	backend behavior and fallbacks
`K`	complexity, memory, and resource limits
`V`	executable verification or certificate evidence
`L`	guide, example, CLI, schema, and test links

A field may say “not applicable,” “not measured,” or “not supported” when that is the true contract. It may not disappear. Literal `null` signatures in the frozen manifest must remain `null`. Inferring a constructor would manufacture an API promise that the manifest does not make. Where no tighter public complexity bound exists, the card says so instead of inventing a benchmark.

76.2 Field provenance and scope

Identity fields are copied from the manifest and checked against runtime reflection. Definition, hypotheses, result, exactness, and failure fields come from implementation, committed contracts, and tests. Dependency, backend, complexity, and evidence fields cite the corresponding source record rather than relying on convention. Reader cross-links are generated last so they cannot alter the semantic fields.

A card covers the exported symbol. It does not promise a separate exhaustive card for every public method and property on an exported class. Structural compatibility checks likewise do not certify every mathematical statement a user might form with the object.

76.3 Completeness and aliases

Let $A(s)$ be the unique anchor for exported name s. Then

$$\text{CompleteCard}(s) \iff \text{FieldsPresent}(s) \wedge \text{SourceMatch}(s) \wedge |A(s)| = 1 \wedge \text{LinksResolve}(s).$$

Callable aliases may share a definition, but each public name still gets an anchor and points to all supported routes. Data records remain name-keyed under the Chapter 75 rule. A profile may reduce drafting duplication, but every rendered card repeats the operational fields needed to use that exported name. A card is rejected if its prose silently widens exactness, platform support, dependencies, or theorem scope beyond the source.

76.4 Appendix A worked closure

Appendix A is the worked implementation of this contract. Its 131 cards match the stable name set: 58 classes, 61 functions, and 12 data exports. They contain 112 exact non-null signatures and 19 literal `null` signatures and expose every stable name through `komorebi_math.stable`, `komorebi_math.v1`, and `komorebi_math.api.v1`, covering all 393 name-preserving routes. The stable documentation comparison reports zero missing, extra, changed, or deprecated records.

The reference bundle verifier reparses Appendices A through C instead of trusting carried counts. It requires exact name-set equality, canonical anchors, section counts, signature equality, implementation identities, operational field labels, and the committed stable, beta, and research-manifest evidence.

76.5 Tier checkpoint and review algorithm

Tier	Inventory	Complete cards in this edition	Status
Stable	131	131	closed in Appendix A
Beta	83	83	closed in Appendix B
Research	1,312	1,312	closed in Appendix C, including C.7 through C.10

The research row records full symbol-card and derived-index closure. Every research namespace and name pair has one complete card. The implementation, alphabetical, signature, and alias ledgers reconcile with those cards and the committed manifests.

The appendix sequence separates module, example, command-line, schema, certificate, exception, backend, complexity, migration, glossary, documentation, and verification records. Complete operational coverage requires the corresponding joins and replay evidence. It cannot be inferred from the presence of an outline or an API inventory.

> **Chapter 76 boundary.** The card schema, provenance rules, alias treatment, explicit non-support vocabulary, parser rules, and tier accounting are complete. Appendix A closes 131 stable cards, Appendix B closes 83 beta cards, and Appendix C closes all 1,312 research cards and all four derived indexes.

77. Executable-example review

Examples are evidence only when the guide records what was executed, what outcome was expected, and what environment made the result meaningful. The shipped inventory has 65 paths: 57 Python programs and 8 PowerShell programs. The Python count and the cross-platform total describe different source sets.

77.1 Exact inventory and evidence status

An example inventory, guide placement, historical replay, representative capability tour, exhaustive Python replay, and complete platform replay are different evidence classes. Each record binds its own source version, file set, environment, and execution scope.

The five later Python examples are `block15_polyphase_refinement.py`, `block16_analysis_synthesis.py`, `block19_measure_integration_worked_example.py`, `block20_typed_expression_worked_example.py`, and `block21_public_capability_tour.py`. Historical PowerShell workflows remain useful examples, but their block names and predecessor wheel references keep them from becoming current release qualification by implication.

77.2 Replay-record contract

For each example path e, the replay ledger stores at least

$$N_e = (id, source, v, env, c, \kappa, r, o_x, o_e, A, h_A, p, d, status),$$

where `source` binds the file digest, v is the package version, `env` the interpreter and environment identity, c the exact command, κ the expected-outcome class, r the observed return code, o_x and o_e the normalized stdout and stderr digests, A the emitted artifacts, h_A their digests, p the platform, and d the dependency profile.

The permitted outcome classes are:

Class	Passing observation
success	return code zero and required assertions or certificate checks pass
expected rejection	declared nonzero code or exception and matching diagnostic
expected unavailability	missing optional backend is reported through the documented route
platform-inapplicable	the record names the unsupported platform and portable alternative

Therefore the example gate is not $r = 0$ for every path. It is

$$G_{\text{example}} = \bigwedge_{e \in \mathcal{E}} \text{Observed}(N_e) \wedge \text{MatchesExpected}(N_e, \kappa_e).$$

An adversarial example that accepts invalid input has failed even if it exits zero. Conversely, a rejection example has passed when it returns the declared nonzero code and diagnostic.

77.3 Review procedure

The authoritative replay uses a clean workspace and the bundled wheel rather than an import from the repository checkout.

1. Create an isolated environment for the example's declared Python version.
2. Install the exact wheel and only the named dependency profile.
3. Invoke a Python example with `python <example-path>` or a PowerShell example with `powershell.exe -NoProfile -ExecutionPolicy Bypass -File <example-path>`.
4. Capture output, return code, report or certificate fields, platform, interpreter, dependency versions, source digest, and artifact digests.
5. Normalize only declared nondeterministic fields such as temporary paths or elapsed time. Never normalize a mathematical value merely because it drifted.
6. Compare the observation with the expected class and store the verdict.
7. Repeat platform-sensitive examples on every claimed platform or keep the missing evidence open.

Randomized examples must record a seed or validate an invariant independent of a particular draw. Numerical examples state tolerances. Exact examples compare exact objects. Certificate examples inspect the claimed identifier, hypotheses, residual, and verification flag rather than merely printing the object.

77.4 Reference commands and mapping boundary

The representative capability tour is:

```
python examples/block21_public_capability_tour.py --json
```

Its committed capability digest is `0e20e32f4ad9004d5248d258813b6acfec7b9e96cc30c001aa6865aba9039fdf`. An interim source sweep can use:

```
python verification/run_block14a2_examples.py --start 0 --end 57 --output <record.json>
```

That runner's historical schema lacks clean-wheel identity, complete environment and source hashes, and PowerShell coverage, so even a successful 57-file run would not close the 65-example gate.

Appendix E supplies the example-record index. The command-line, schema, certificate, failure, dependency, resource, and verification joins have separate evidence requirements. Placement must not be reported as exhaustive execution validation.

> **Chapter 77 boundary.** The 65-example inventory, evidence-status ledger, expected-outcome model, replay record, and review procedure are complete. All 65 paths are placed, but a current exhaustive replay ledger and current Windows evidence are not claimed.

78. Connected tutorial review

Chapters 64 through 70 provide seven workflows and 34 connected subrecipes spanning certificate-checked algebra, arithmetic, signal processing, nonlinear methods, integration and typed expressions, finite quantum and deformation models, document export, and reproducibility. The criteria below distinguish readable explanation from complete execution evidence.

78.1 Tutorial families

Chapter	Connected family	Representative source joins
64	algebra and coordinates	quickstart, coordinate, and analysis/synthesis examples
65	arithmetic and refinement	sequence, Mahler-Cartier, prime-power, and polyphase examples
66	signal workflows	production DSP, filter bank, and singular-recovery examples
67	nonlinear and dynamics	jets, trees, transport, Markov, and Feshbach examples
68	integration and typed expressions	measure/integration and typed-expression examples
69	advanced finite systems	quantum, deformation, finite-image, and finite Langlands examples
70	export and reproducibility	report export, PowerShell export, and repository handoff routes

Each family includes representative output and explicit failure boundaries. Qualification additionally requires a fresh replay record for every declared profile and platform.

78.2 Tutorial record

A connected tutorial T is a sequence of checkpoints rather than one long transcript:

$$T = (goal, prerequisites, objects, steps, checkpoints, claim, \\ replay, extensions, platform, profile, expected, evidence).$$

Every checkpoint identifies the command or code cell, its assertion, normalized observation, evidence record, and the earlier artifact it consumes. This makes a tutorial restartable and reveals accidental dependence on a developer tree, ambient cache, or undeclared optional package.

Each review asks:

- Can a reader install the declared profile from the delivered wheel?
- Do commands use current filenames, options, and result types?
- Are exact, numerical, heuristic, and certificate-backed claims labeled?
- Do expected failures check their diagnostics?
- Are intermediate files written to explicit, disposable locations?
- Does the Windows route use PowerShell-safe quoting and the POSIX route use shell-safe quoting without pretending the syntaxes are identical?
- Can each checkpoint be rerun without hidden state or destructive overwrite?

78.3 Clean-wheel and platform matrix

Narrative completion and replay completion are separate states.

Evidence level	Meaning
prose	steps, boundaries, and expected results are complete
source-linked	symbols, examples, CLI leaves, and schemas have explicit joins
representative	the current capability tour exercises a connected route
clean-wheel	every tutorial passes from an isolated wheel install
cross-platform	every claimed Windows and POSIX route has current evidence
reproducible	reruns match declared exact, tolerance, and digest rules

Clean-wheel means imports resolve from installed `site-packages`, source `PYTHONPATH` is removed, the working directory and dependency profile are declared, artifacts and cleanup are recorded, and restart points consume only their declared state. Optional-backend branches may be conditionally closed: the tutorial shows the success branch when installed and the documented unavailability branch when absent. Shell-sensitive workflows receive both PowerShell and POSIX evidence. Platform-neutral Python is not duplicated merely for cosmetic symmetry.

78.4 Review algorithm and evidence boundary

1. Build or select the exact wheel named by the freeze record.
2. Create one clean environment per dependency profile and claimed platform.
3. Execute each checkpoint in order, then replay restartable checkpoints from their declared saved state.
4. Match structured results before comparing presentation text.
5. Run the tutorial's expected-failure and resource-limit branches.
6. Store the command, platform, dependencies, source digest, observation, and verdict for every checkpoint.
7. Reject stale wheel names, obsolete CLI flags, developer-checkout imports, undeclared files, or claims whose certificates do not match the observation.

Complete tutorial qualification requires replay records tied to the exact wheel, dependency profiles, and claimed platforms. A finished explanation does not supply that operational evidence by itself.

> **Chapter 78 boundary.** A connected tutorial records inputs, checkpoints, certificates, expected failures, dependencies, and restart state. Claims about clean installation or platform parity require separate replay evidence.

79. Warning, limitation, and drift audit

A closing audit must distinguish failure, warning, limitation, skip, and drift. Collapsing them into a single "passed" flag makes a report easy to read and unsafe to trust.

79.1 Status vocabulary

Class	Meaning	Gate effect
passed	a required check ran and matched its contract	contributes to the named gate only
failed	a required check ran and contradicted its contract	closes the gate as failed
warning	a reviewable condition outside the check's default fail set	non-gating only when policy says so
limitation	the implementation or evidence intentionally does not claim a capability	remains visible and may keep a broader gate open
not executed	a required or optional check did not run	never counts as a pass
expected failure	a negative control returned its declared rejection	validates that rejection, not the missing positive claim
historical	an internally valid record for an older source or platform	informative, never current execution
planned	a required artifact or check has a contract but does not yet exist	open
drift	two supposed current sources disagree	blocks publication until reconciled

Warnings are not intrinsically harmless. The current quick publication report can pass while warning that full tests were not requested and MkDocs was skipped. That report is valid for its 14-check quick contract, but it cannot satisfy the strict full-guide gate.

79.2 Coverage versus placement

For surface S, use three separate ratios:

$$I(S) = \frac{\text{inventoried}}{|S|}, \qquad P(S) = \frac{\text{placed}}{|S|}, \qquad C(S) = \frac{\text{complete records}}{|S|}.$$

An item may be inventoried and placed without having a complete card, replay, or crosswalk. Each surface requires its own inventory, completion, and qualification record.

Coverage is evaluated separately for API tiers, commands, examples, codecs, verification suites, tests, documentation, and implementation modules.

`Placed(201/201)` and `Placed(65/65)` are outline-placement results. They do not by themselves establish complete module cards or executable-example replay.

79.3 Warning and limitation records

A warning record identifies the named check, invocation mode, source, environment, observation, and gate effect. Historical, skipped, and selectively inspected evidence must retain those distinctions.

79.4 Recording drift corrections

A drift record binds both the superseded value and the accepted replacement to their source identities. Canonical payload digests and raw-file checksums remain different evidence types.

79.5 Drift-audit procedure

1. Recompute inventories and canonical digests from decoded source contracts.
2. Recompute raw checksums for exact distributable files.
3. Search current prose, commands, and support files for predecessor names, deprecated options, obsolete digests, and unconditional platform claims.
4. Compare every generated report with the source identity it claims to cover.
5. Require an explicit disposition for every mismatch: update the current statement, mark the record historical, or leave a blocking issue.
6. Reject a broad success claim derived only from aggregate `passed: true` when a required named check is absent or skipped.

The disposition log is itself review evidence: it names the conflicting sources, the chosen authority, the reason for the choice, and the first edition whose published text contains the correction.

> **Chapter 79 boundary.** The status vocabulary, per-surface checkpoint, current warning ledger, digest corrections, and audit algorithm are complete. The audit reports open work instead of converting limitations and skipped checks into passes.

80. Coverage ledger and symbol index

Human-readable appendices answer “what does this do?” The coverage ledger and symbol index answer “is every source item accounted for, and where?” They are different deterministic artifacts and neither can be reconstructed reliably by scraping the rendered PDF.

80.1 Coverage is a vector

For every source set T, distinguish

$$\mathrm{Placed}(T), \qquad \mathrm{Documented}(T), \qquad \mathrm{Qualified}(T).$$

Placement means an item has a guide destination. Documentation means its required record is complete. Qualification means the relevant examples, links, tests, and platform predicates have current evidence. These values may differ without inconsistency, but a publisher must never substitute the larger one for the smaller.

80.2 `coverage.json`

The coverage-ledger specification records one row per source surface and one disposition per item. Its minimum envelope is:

```
{
  "schema": "komorebi-math.guide-coverage",
  "schema_version": 1,
  "package_version": "1.0.0b4",
  "manual_block": 16,
  "source_sha256": {},
  "surfaces": [],
  "payload_sha256": "<canonical digest>"
}
```

A surface row contains `domain`, `source`, `expected`, `placed`, `complete`, `validated`, `missing`, and `status`. Each item stores its source key, canonical identity, guide anchor, completion state, evidence links, and open reason. Counts are derived from item rows. They are never hand-entered independently.

80.3 `symbol_index.json`

The symbol-index specification is search-oriented. Each exported-name row contains `qualified_name`, `tier`, `kind`, `signature`, `implementation_module`, `qualname`, `canonical_anchor`, `aliases`, `guide_locations`, and `status`. Evidence joins add examples, CLI leaves, schemas, certificates, exceptions, dependencies, tests, exactness, and backend labels.

Class and function aliases may point to one canonical definition. Data exports remain independently keyed unless source declares an alias. Index generation must therefore use the same π rule as the coverage ledger and Appendix A.

80.4 Deterministic generation

The generation sequence is fixed:

$$\text{source parse} \to \text{canonicalize} \to \text{join guide records} \to \text{validate} \to \text{canonical JSON} \to \text{digest}.$$

Rows are sorted by explicit stable keys, paths use forward slashes, text is UTF-8, object keys are sorted for the payload digest, and no timestamp or absolute workspace path enters the hashed payload. The validator recomputes surface counts, checks unique anchors, rejects unresolved internal targets, and requires the coverage and index records to agree on every exported name.

A row marked complete must resolve to exactly one current anchor. The final anchor gate checks fragments, not merely destination files, and the index gate rejects duplicate qualified names, missing source items, extra current items, and conflicting aliases.

80.5 Ledger and index requirements

The ledger accounts for stable, beta, and research exports, defining owners, CLI leaves, examples, verification suites, codecs and migrations, documentation, and tests. Every completion claim resolves to its own evidence rows rather than inheriting a larger aggregate count.

> **Chapter 80 boundary.** The ledger and index are explicit data contracts. A schema description does not establish that a concrete record was generated, validated, or qualified on a particular platform.

81. Site and PDF build closure

The companion documentation site and the cumulative technical manual are independent publication graphs. The site validates curated navigation, links, and browser presentation. The manual validates the full reader sequence, print pagination, mathematical composition, and offline readability. Success in one format never substitutes for the other.

81.1 Independent publication graphs

The repository site consumes its MkDocs configuration and documentation corpus:

$$(\texttt{mkdocs.yml}, 71\ \texttt{docs/*.md}) \longrightarrow \texttt{site/}.$$

The technical manual consumes the cumulative manual Markdown plus its metadata, header, and two Lua filters:

$$(\text{manual Markdown}, \text{build assets}) \longrightarrow \text{standalone LaTeX} \longrightarrow \text{PDF}.$$

The 57 configured navigation entries leave 14 documentation files outside the curated navigation. No configured target is missing, but the final navigation policy must give those 14 files an explicit disposition. The site is therefore a companion, not an HTML rendering of this thousand-page manual.

81.2 Strict MkDocs and full-test gate

From the repository root, the normative commands are:

```
python -m mkdocs build --strict
python -m pytest -q --tb=short tests
```

The final source gate requires both named checks:

$$G_{\text{strict}} = \text{PresentPass}(\text{full test suite}, r = 0) \wedge \text{PresentPass}(\text{strict MkDocs build}, r = 0).$$

In the reference publication report, `mode == "full"` means full pytest was requested. It does not prove MkDocs ran. The handoff loader currently checks report schema, aggregate pass, full mode, and pytest return code, but does not itself require a passed named strict-MkDocs check. The final documentation publisher must enforce the stronger predicate above rather than attribute it to the current loader.

An environment record must distinguish tools installed on the build host from checks actually executed. A carried full-test report with strict documentation skipped cannot establish a fresh strict site build.

81.3 Reference technical-manual build path

The reference baseline uses this build path from its `manual` directory:

```
pandoc .\Komorebi_Math_User_Guide_Progressive_Edition_Block16.md `
  --from=markdown+tex_math_single_backslash `
  --to=latex --standalone --top-level-division=part `
  --metadata-file=.\build-assets\komorebi_block16_technical_manual_metadata.yaml `
  --include-in-header=.\build-assets\komorebi_block16_technical_manual_header.tex `
  --lua-filter=.\build-assets\komorebi_technical_manual_layout.lua `
  --lua-filter=.\build-assets\komorebi_content_filter.lua `
  --highlight-style=pygments `
  --output=.\Komorebi_Math_User_Guide_Technical_Manual_Edition_Block16.tex

latexmk -pdf -interaction=nonstopmode -halt-on-error -file-line-error `
  .\Komorebi_Math_User_Guide_Technical_Manual_Edition_Block16.tex
```

PDF closure requires more than a successful TeX exit code. The validation record checks page size and count, final EOF, Ghostscript traversal, embedded fonts with no Type 3 font, unresolved-reference and rerun messages, new overfull boxes, extracted heading presence, and visual rendering of the changed chapters and transitions. Inherited warnings remain identified by location. A new chapter may not hide behind them.

81.4 Warning and visual-QA policy

The PDF gate does not require a literally empty warning log. It requires no fatal diagnostic, no unresolved reference, no unexplained new overfull warning in the changed span, and no material clipping or collision. Visual inspection covers every changed physical page plus the transition into and out of the closing block. A selective inspection is reported as selective, not upgraded to an all-page visual review.

PDF reproducibility is likewise an independent claim. The deterministic wheel, source distribution, and outer ZIP do not prove two independent PDF compiles are byte-identical. The build record states which artifacts have replay or byte reproducibility evidence.

81.5 Reproducible build record and current boundary

The generic `build_record.json` contract binds source digests, exact commands, tool versions, dependency identity, named-check results, artifact sizes and SHA-256 values, accepted warnings, platform evidence, and clean-replay result. It distinguishes a documented non-material warning from a skipped required check. The final site, `coverage.json`, `symbol_index.json`, PDF, and sources all become named artifacts in that record.

A bounded manual build does not by itself establish a strict companion site, full source-test execution, generated coverage and symbol indexes, or current platform qualification. Each requires its own named evidence.

> **Chapter 81 boundary.** Site validation, PDF layout, source testing, structured records, reproducibility, and platform execution are distinct predicates. A publication record must identify which predicates were tested.

82. Publication requirements and reference architecture

This chapter defines publication requirements separately from editorial completion. Finished prose does not establish unexecuted software, platform, or external-publication claims.

82.1 Three-layer source model

The manual separates reader explanations, exhaustive reference records, and retained design specifications:

$$\text{GuideSource} = \text{Reader}_{0:82,A:B} \bowtie \text{Pending}_{C:O} \bowtie \text{Regression}_{83:88}\,.$$

Reader explanations present the mathematical constructions and operational contracts. Reference appendices organize the detailed source records. The design specifications preserve equations, hypotheses, failures, examples, and source obligations for independent review. A specification does not override a more precise implemented contract.

When layers disagree, first consult the live source and committed contracts for the declared version, then the reader explanations and their checks, and finally the retained design specifications. Historical evidence remains tied to its source version and is identified as historical.

82.2 Manual-completion predicate

Let R_{16} mean that each primary Chapter 75 through 82 occurs once in order, contains its required boundary and operational fields, matches the live counts and digests, preserves the stable Appendix A contract, and states the open work without a false whole-guide claim. Let P_{16} mean that the canonical Markdown was rendered, structurally and visually validated, archived twice with byte identity, safely extracted, and verified again.

$$\text{ReaderReady}_{16} = R_{16}, \qquad \text{BoundedBuild}_{16} = R_{16} \wedge P_{16}.$$

The reference verifier evaluates R_{16} separately from stable Appendix A closure and bundle integrity. This makes the reader boundary machine-visible without substituting editorial completeness for operational evidence.

82.3 Appendix gate matrix

Appendix	Reference obligation
A	131 frozen stable cards
B	83 beta cards
C	1,312 research cards and four derived indexes
D	300 package-module cards and 5 external owner rows
E	complete example records and replay joins
F	46-leaf CLI reference and recipe crosswalk
G	51 codec records and adjacent migration
H	certificate and theorem-ID index
I	exceptions and diagnostic cookbook
J	backend and dependency matrix
K	complexity, memory, and budget tables
L	migration and deprecation tables
M	glossary and notation index
N	71-file documentation crosswalk and navigation policy

Appendix	Reference obligation
O	test and verification crosswalk

82.4 Whole-guide definition of done

Let $G_A, \dots, G_O$ be the appendix gates, G_{ex} the complete example and tutorial replay gate, G_{strict} the named full-test and strict-MkDocs gate, G_{pdf} the final PDF gate, G_{json} the coverage, index, and build-record gate, $G_{platform}$ the current evidence required by the release claim, and G_{drift} the zero-unresolved-current-drift gate. Then

$$\text{CompleteGuide} \iff \left(\bigwedge_{X=A}^{O} G_X \right) \wedge G_{ex} \wedge G_{strict} \wedge G_{pdf} \wedge G_{json} \wedge G_{platform} \wedge G_{drift}.$$

This predicate requires complete stable, beta, research, CLI, example, codec, suite, module, documentation, and test coverage. It also requires every snippet to match its expected outcome, every certificate claim to match its record, all local links and fragments to resolve, and every required artifact to be bound by the final build record.

82.5 Evaluating the publication predicate

Evaluate each conjunct against named source, build, replay, and platform records. A passing bounded reference check does not fill an absent example replay, test result, site check, coverage ledger, or external publication record.

An all-one target vector retained later in the document is normative, not an observation. `Placed(201/201)` and `Placed(65/65)` similarly describe outline placement, not complete module cards or example replay.

82.6 Publication decision and maintainer handoff

A distribution title must match its demonstrated scope. A bounded reference release may be described as such when its identity, validation, and replay records are explicit. A whole-guide completion claim requires every conjunct of the stated predicate.

The local Windows qualification entry point is:

```
powershell.exe -NoProfile -ExecutionPolicy Bypass -File .\Run_Block16_Full_Verification.ps1
```

The underlying source gate may be invoked with:

```
powershell.exe -NoProfile -ExecutionPolicy Bypass -File .\Run_Block21_Publication_Gate.ps1 -Python
    ↪ "$env:CONDA_PREFIX\python.exe"
```

The final gate rejects predecessor wheel names, obsolete CLI options, stale support-matrix filenames, historical aggregate verifiers presented as current, required checks reported only as skipped warnings, and artifacts not bound to their source digests.

82.7 Preserved chapter contract

For regression review, each retained chapter card instantiates

$$\mathfrak{C} = (\Sigma, \mathcal{T}, \mathcal{M}, \mathcal{H}, \mathcal{I}, \mathcal{R}, \mathcal{F}, \mathcal{E}, \mathcal{Q})$$

using implemented objects and current contracts. These tuples remain useful as checklists even after their reader counterparts are complete. They never override live source and they never create a public claim by themselves.

82.8 Design-specification crosswalk

Specification family	Reader chapters
Foundations	0 through 20
Discrete systems	21 through 27
Algorithms and signals	28 through 36A
Nonlinear systems and dynamics	37 through 46
Advanced finite systems	47 through 58
Interfaces and publication	59 through 82 and Appendices A through O
Design specifications	83 through 88

82.9 Retained-specification acceptance predicate

Let $B = \{B_f, B_d, B_n, B_{nl}, B_a, B_i\}$ denote the six marked regression blocks in Chapters 83 through 88. Their preservation gate is

$$\mathrm{Accept}_{\mathrm{reg}} = \bigwedge_{b \in B} \left(P_b \wedge M_b \wedge R_b \wedge S_b \wedge X_b\right),$$

where P_b is standalone and integrated parity, M_b balanced mathematical markup, R_b balanced markers and retained numbering, S_b source faithfulness, and X_b explicit exactness, failure, and example coverage. This is a preservation predicate, not `CompleteGuide`.

> **Chapter 82 boundary.** Reference coverage, replay, site and PDF quality, source testing, platform qualification, and external publication remain distinct claims. The design specifications preserve their requirements without asserting that an absent record has been supplied.

83. Foundations, refinement, coordinates, and analysis-synthesis

Specifications for foundations and coordinate systems

The sections below deepen the existing topology without creating new public claims. A displayed equation is either an implemented finite rule, a validation invariant, or a marked example target. Numerical equality always means a residual comparison at an explicit tolerance.

Chapter 0: Coverage contract

0.A Notation and typed sets

- Public surfaces:
$$\mathcal{S}_s, \mathcal{S}_b, \mathcal{S}_r, \mathcal{C}, \mathcal{E}, \mathcal{V}.$$
- Canonical symbol record:
$$s = (N, n, k, m, q, \sigma, \ell),$$
where N is export namespace, n name, k kind, $m.q$ implementation identity, σ reflected signature, and ℓ stability label.
- Canonicalization map:
$$\pi : s \mapsto (m, q), \qquad \text{Aliases}(m, q) = \pi^{-1}(m, q).$$
- Guide anchor map:
$$\alpha : \mathcal{S}_s \cup \mathcal{S}_b \cup \mathcal{S}_r \to \mathcal{A}.$$

0.B Defining audit algorithm

1. Read each frozen API manifest and each defining module.
2. Normalize aliases by π, retaining every exported path.
3. Assign one canonical anchor $\alpha(s)$ per implementation identity.
4. Attach signatures, examples, CLI routes, tests, theorem identifiers, codecs, and failure contracts as edges in a documentation graph.
5. Reject the build if an exported symbol has no anchor or if one alias resolves to incompatible cards.

0.C Hypotheses and boundaries

- Manifest membership is version-specific: $v = 1.0.0b4$.
- Private names are excluded unless they define behavior observable through a public symbol.
- Historical contracts are evidence, not current API definitions.
- A finite certificate is not promoted to a continuum or asymptotic theorem.

0.D Coverage invariants and certificate target

- Unique placement:
$$\forall s, \quad |\alpha(s)| = 1.$$
- Example placement and CLI exercise:
$$\forall e \in \mathcal{E} : \ |\,\text{GuideMap}(e)| \geq 1, \qquad \forall c \in \mathcal{C} : \ |\,\text{Recipe}(c)| \geq 1.$$
- Recorded inventory target: 131 stable, 83 beta, 1,312 research entries. 201 public implementation owners. 65 shipped executable examples.
- `[PLANNED]` A later guide build emits a machine-readable coverage ledger L_{guide} and digest $h(L_{guide})$.

0.E Failure and edge cases

- Alias collision: equal export path, unequal implementation identity.
- Signature drift: manifest $\sigma_m \neq \sigma_{runtime}$.
- Orphan example, command, codec, theorem identifier, or public module.
- Duplicate canonical anchors or an anchor that silently merges semantically distinct overloads.

0.F Example specifications

- **E0: canonical alias:** input `stable.CoordinateTransform`, `v1.CoordinateTransform`, `api.v1.CoordinateTransform`. Assert one implementation card and three aliases.
- **E1: coverage row:** choose s. Resolve $s \to \alpha(s) \to \{\sigma, H, C, E, T\}$. Assert all required fields are populated.
- **E2: deliberate drift:** perturb one reflected parameter. Expect manifest comparison failure with the exact symbol path.

Chapter 1: Editorial and symbolic grammar

1.A Notation and type grammar

- Exact scalar and finite containers:
$$q \in \mathbb{Q}, \quad v \in \mathbb{Q}^n, \quad A \in \mathbb{Q}^{m \times n}.$$
- Numerical scalar and arrays:
$$z \in \mathbb{R} \text{ or } \mathbb{C}, \quad A \in \mathbb{F}^{m \times n}, \quad \mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}.$$
- Symbol card type:
$$\mathfrak{S} = (\text{id}, \sigma, X, Y, f, H, I, \chi, R, F, P, B, K, E).$$
- Example card type:
$$\mathfrak{E} = (I, H, A, O, C, F, R), \qquad E_j \in \{E_0, E_1, E_2, E_3, E_4\}.$$

1.B Defining editorial rules

- Every callable is displayed as a typed map $f : X \to Y$, then as its exact Python signature.
- Every class separates constructor invariants, immutable/public fields, properties, methods, and returned record types.
- Every equality is tagged `[EXACT]`, `[NUMERICAL]`, `[CONDITIONAL]`, `[HEURISTIC]`, or `[PLANNED]`.
- `Certificate.require()` is shown once in every certificate-producing family.
- Complexity is stated only for implemented finite algorithms and includes explicit resource guards when present.

1.C Hypotheses and conventions

- Vectors are columns. Matrices act on the left. A^* is conjugate transpose.
- Polynomial tuples use ascending powers.
- Signal convolution is signal-first.
- Exact rational objects are not silently converted into numerical proof records.
- Numerical tolerances bound residuals. They do not redefine exact equality.

1.D Documentation invariants

- Domain/codomain dimensions in prose match runtime dimension checks.
- All unchecked assumptions occur inside the card and certificate discussion.
- Each example identifies expected exactness and backend.
- Portable objects list tag, schema version, fields, and rejection rules.

1.E Failure and edge cases

- Ambiguous use of "projector" for a redundant reconstruction component.
- Reversing transform composition or path application order.
- Omitting the distinction between transpose and adjoint.
- Calling a conditional result exact because its numerical residual is small.

1.F Example specifications

- **E0: exact card:** $f : \mathbb{Q}^2 \to \mathbb{Q}^2$, $f(v) = Av$. Show hypotheses, inverse invariant, exact return.
- **E1: numerical card:** $f : \mathbb{C}^n \to \mathbb{C}^n$. Show $\|f^{-1}f - I\| \le \tau$ and condition number.
- **E2: conditional card:** value x, checked finite identities, nonempty $H_?$. Assert the conclusion remains conditional.

Part I: Orientation and first execution

Chapter 2: What Komorebi Math is

2.A Notation and typed pipeline

- Unified stages:

$$\mathsf{U} = \{\text{seed}, \text{address}, \text{operate}, \text{project}, \text{transfer}, \text{refine}, \text{constrain}, \text{complete}, \text{reconstruct}\}.$$

- Finite stage chain:

$$S \to W \to \rho(W) \to (P_\alpha x)_\alpha \to (Q_\beta T P_\alpha)_{\beta,\alpha} \to \mathcal{R} \to \Delta \to x.$$

- `UnifiedSystem` data:

$$U = (G, \rho, \Sigma, P, \{T_i\}, \mathcal{T}, M),$$

  where fields may be absent and are validated only when present.

2.B Implemented maps

- `validate: UnifiedSystem -> Certificate`.
- `analyze: X -> PacketCoordinates`, requiring a packet system.
- `block_operator: name -> PacketOperator`, requiring the named ambient operator.
- `refine_coordinates, coarsen_coordinates: (c,i,j) -> c'`, requiring a refinement tower.
- `obstruction: (L,d) -> LinearObstructionProblem`.
- `summary: UnifiedSystem -> dict[str, Any]`.

2.C Defining equations and composition boundaries

- Grammar relation check: $\rho(\sum_w c_w w) = 0$.
- Seed condition: $\text{span}\{as : a \in \mathcal{A}, s \in S\} = X$.
- Packet condition: $P_\alpha^2 = P_\alpha$, $P_\alpha P_\beta = 0$, $\sum_\alpha P_\alpha = I$.
- Transfer block: $T_{\beta\alpha} = Q_\beta T P_\alpha$.
- The `COMPLETE` stage is explicitly marked `implemented_in_alpha=False`. The guide must not imply `UnifiedSystem` executes a general inverse-limit completion.

2.D Hypotheses and certificates

- Realization grammar identity must be object-consistent with the declared grammar.
- Seed and packet ambient dimensions must agree.
- Named operators must be square on the packet ambient space.
- Declared packet system must equal a level of the refinement tower up to `PacketSystem.equivalent`.
- `validate()` aggregates relation, seed, packet, and tower residuals. Exactness becomes numerical if any constituent certificate is numerical.

2.E Failure and edge cases

- Missing packet system for analysis or block resolution.
- Unknown operator name.
- Mismatched grammar/realization or ambient dimension.
- Treating the common language as a claim that domain-specific mathematical meanings are identical.

2.F Example specifications

- **E0: minimal finite system:** $G = \langle a : X \to X \mid a^2 - a = 0 \rangle$. One seed. Two packets. Validate and summarize.
- **E1: full finite path:** $x \mapsto (P_0 x, P_1 x) \mapsto (T_{ij}) \mapsto \mathcal{R}_{0\to 1} \mapsto x$.
- **E2: incomplete system:** instantiate metadata only. Show which summary fields are empty without claiming validation of absent structures.
- **E3: incompatible tower:** choose P not equivalent to any tower level. Expect `DimensionError`.

Chapter 3: Installation and environment profiles

3.A Environment objects and dependency lattice

- Runtime floor: Python ≥ 3.11.
- Core environment:

$$\mathcal{P}_0 = \{\texttt{komorebi-math}, \texttt{numpy}\}.$$

- Selected optional-dependency sets (not a complete ledger of the declared `plot`, `jax`, `torch`, `test`, `docs`, `build`, `dev`, and `all` extras):

$$\begin{aligned}
\mathcal{P}_{exact} &= \{\texttt{sympy}\},\\
\mathcal{P}_{scientific} &= \{\texttt{scipy}, \texttt{mpmath}\},\\
\mathcal{P}_{yaml} &= \{\texttt{PyYAML}\},\\
\mathcal{P}_{autodiff} &= \{\texttt{jax}, \texttt{torch}\},\\
\mathcal{P}_{publication} &= \{\texttt{pytest}, \texttt{build}, \texttt{setuptools}, \texttt{wheel}, \texttt{mkdocs}, \texttt{sympy}, \texttt{scipy}, \texttt{mpmath}, \texttt{PyYAML}\}.
\end{aligned}$$

3.B Settings maps

- `Settings = (backend: str, tolerance: float, validate_on_construction: bool)`.
- Default:
$$s_0 = (\texttt{"numpy"}, 10^{-10}, \text{True}).$$
- `get_settings: 1 -> Settings`.
- `configure(*, backend: str | None = None, tolerance: float | None = None, validate_on_construction: bool | None = None) -> Settings` mutates the current context.
- `settings_context(**changes: object) -> Iterator[Settings]` is the decorated context-manager signature. Entering yields the changed settings and exit restores the prior context token.

3.C Installation and probe algorithm

1. Install wheel, editable source, or rebuilt sdist into a chosen interpreter.
2. Verify `python -c "import komorebi_math"` and package identity.
3. Evaluate `available_backends()` without importing absent optional packages.
4. Select a backend only at the first operation requiring it.
5. Run the smallest relevant certificate before a full publication gate.

3.D Hypotheses and invariants

- `numpy` is mandatory. Other dependencies are optional and feature-scoped.
- `settings_context` restores the exact prior context even after an exception.
- Backend discovery reports presence, not hardware qualification.
- CUDA/CuPy presence does not certify a CUDA execution path or numerical equivalence.

3.E Failure and edge cases

- Missing optional backend produces `BackendUnavailableError`, not a core import failure.
- Unknown backend name is rejected.
- Environment contains incompatible third-party versions even if import succeeds. Use `pip check` in qualification.
- A PowerShell prompt can display a duplicated conda prefix without implying two active interpreters. Record the resolved `python.exe` path.

3.F Example specifications

- **E0: core:** clean environment $\mathcal{P}_0$. Import, print version, perform one NumPy certificate.
- **E1: exact:** install `.[exact]`. `get_backend("sympy").exact=True`. Certify one rational packet system.
- **E2: scoped settings:** outer s_0, inner tolerance 10^{-14}, forced exception, assert post-context state s_0.
- **E3: absent optional:** probe `sympy=False`. Request it. Assert isolated `BackendUnavailableError` while NumPy remains usable.

Chapter 4: First verified program

4.A Minimal data and maps

- Vector $x \in \mathbb{F}^n$.
- Complete packet system $P = (P_0, \dots, P_{r-1})$.
- Analysis and synthesis:

$$\mathcal{A}_P(x) = (P_\alpha x)_\alpha, \qquad \mathcal{S}_P((x_\alpha)) = \sum_\alpha x_\alpha.$$

- Exact basis transform $T_{B \leftarrow A} \in \mathrm{GL}_n(\mathbb{Q})$.

4.B Execution algorithm

1. Query package identity and enabled feature records through the CLI.
2. Construct two coordinate projectors and validate `PacketSystem.certificate().require()`.
3. Analyze x, reconstruct $\hat{x}$, assert $\hat{x} = x$ or residual $\leq \tau$.
4. Apply a rational coordinate transform, invert it, and assert exact roundtrip.
5. Inspect `valid`, `exactness`, `residuals`, `assumptions_checked`, `assumptions_unchecked`, and `theorem_id`.

4.C Hypotheses and invariants

- Projectors share one backend and ambient dimension.
- Exact coordinate transform is square and invertible.
- Packet coordinates are bound to their originating `PacketSystem`.
- The public capability tour is deterministic for its declared finite inputs. Its recorded digest is part of release evidence, not a mathematical theorem.

4.D Failure and edge cases

- Invalid projector family fails construction when validation is enabled.
- Supplying coordinates from another packet system fails synthesis/application compatibility.
- A singular exact transform cannot produce an inverse.
- `komorebi features` reports feature status. It does not install optional dependencies.

4.E Example specifications

- **E0: packet roundtrip:** $P_0 = \mathrm{diag}(1, 0)$, $P_1 = \mathrm{diag}(0, 1)$, $x = (2, 3)^T$. Expect packets $(2, 0)^T, (0, 3)^T$.
- **E1: exact shear:** $T = \begin{bmatrix} 1 & 1/2 \\ 0 & 1 \end{bmatrix}$. Check $T^{-1}Tv = v$ over $\mathbb{Q}^2$.
- **E2: certificate anatomy:** perturb P_1. Capture invalid residual rather than calling `.require()` first.
- **E3: capability tour:** run shipped `block21_public_capability_tour.py`. Compare the structured record to its committed finite assertions.

Part II: Trust, types, and execution semantics

Chapter 5: Certificates and result types

> **Reference scope.** Chapter 5 is authoritative for explanation and examples. This retained card is the source-based specification. It uses the certificate normal form introduced in Chapter 1 rather than defining a competing tuple notation.

5.A Runtime records and exact field map

- `Exactness` is a `StrEnum` with the five values

$$\mathsf{X} = \{\text{exact}, \text{numerical}, \text{conditional}, \text{heuristic}, \text{planned}\}.$$

  The runtime enum has no ordering or promotion operation. Chapter 1's strongest-to-weakest ordering is an editorial reading rule only.
- `Certificate` is a frozen, slotted dataclass with the runtime fields

$$\mathfrak{K} = (v, e, r, \tau, h_c, h_u, d, t, m),$$

  mapped exactly as follows:

Symbol	Runtime field	Runtime annotation/default
v	`valid`	`bool`
e	`exactness`	`Exactness`
r	`residuals`	`dict[str, float]`, default `{}`
τ	`tolerance`	`float | None`, default `None`
h_c	`assumptions_checked`	`tuple[str, ...]`, default `()`
h_u	`assumptions_unchecked`	`tuple[str, ...]`, default `()`
d	`diagnostics`	`dict[str, Any]`, default `{}`
t	`theorem_id`	`str | None`, default `None`
m	`message`	`str`, default `""`

- `ComputationResult[T]` is a separate frozen, slotted dataclass with exactly `value: T` and `certificate: Certificate`. It adds the properties `valid` and `exact`, plus `require()`.
- `ConditionalResult[T]` is another frozen, slotted dataclass with exactly `value: T` and `certificate: Certificate`. Its only custom runtime operation is `__post_init__`, which requires `certificate.exactness is Exactness.CONDITIONAL`.
- `ConditionalResult` is not a subclass of `ComputationResult`. In this release it does **not** provide `.valid`, `.exact`, `.require()`, `.to_dict()`, or `.to_json()`.

5.B Operational semantics

- Certificate acceptance is

$$\text{Certificate.require}(\mathfrak{K}) = \begin{cases} \mathfrak{K}, & v = \mathsf{True}, \\ \text{ValidationError}(m), & v = \mathsf{False},\ m \neq \texttt{""}, \\ \text{ValidationError}(\texttt{"certificate validation failed"}), & v = \mathsf{False},\ m = \texttt{""}. \end{cases}$$

- `ComputationResult.valid` returns `certificate.valid`.
- `ComputationResult.exact` is the identity test `certificate.exactness is Exactness.EXACT`. It does not also test validity.
- `ComputationResult.require()` first calls `certificate.require()` and then returns the stored value.
- `Certificate.to_dict()` converts the dataclass recursively and replaces the enum object with `exactness.value`.
- `Certificate.to_json(indent=2)` serializes that mapping with sorted keys and `default=str`. These serialization methods belong to `Certificate`, not to either result wrapper.

5.C Validity, exactness, and assumptions

- `Certificate` stores an API-supplied Boolean. The record class does not recompute `valid` from residuals, tolerance, assumptions, theorem ID, or diagnostics.
- The dataclass does not enforce cross-field implications. In particular:

$$v \not\Rightarrow e = \text{exact}, \qquad e = \text{exact} \not\Rightarrow v, \qquad r = 0 \not\Rightarrow e = \text{exact}.$$

- An identity-checking exact producer normally sets validity from exact finite equality. A numerical producer normally sets validity from a documented scaled residual bound. Those are producer contracts, not behavior supplied by the record class.
- `ConditionalResult` enforces only the exactness category. It does not require `certificate.valid` to be true and does not require a nonempty `assumptions_unchecked` tuple. Producing APIs remain responsible for those stronger domain-specific invariants.
- A valid conditional certificate means that the implemented finite construction passed under its declared record. It does not establish the truth of unchecked assumptions.

5.D Hypotheses and invariants

- Residuals are annotated as machine-readable floats, including exact-zero residuals represented as `0.0`. Runtime construction does not independently validate every dictionary value against that annotation.
- Exactness is determined by the executed operation and scalar/backend path, not by a user's desired conclusion.
- A theorem ID names an implemented finite theorem or contract when a producer supplies one. The field may be absent.
- Diagnostics are explanatory data. They neither override `valid` nor promote `exactness`.
- JSON serialization of arbitrary diagnostic objects uses string fallback and is not a general object-reconstruction protocol.

5.E Failure and edge cases

- Invalid certificate with an empty message uses the standard failure detail.
- Constructing `ConditionalResult` from exact, numerical, heuristic, or planned exactness raises the built-in `ValueError`, not `ValidationError`.
- `ComputationResult.exact` may be true even when its certificate is invalid. Use `.valid` or `.require()` for acceptance.
- Calling `.require()` is an explicit control-flow boundary. Inspecting a certificate without calling it leaves the caller responsible for the next action.
- Portable persistence of domain records is a separate codec contract. A certificate JSON rendering alone is not that persistence guarantee.

5.F Example checklist

- **E0: exact record:** valid exact certificate. `.require()` returns the same certificate object.
- **E1: numerical record:** residual below an explicit tolerance. Validity is true while exactness remains numerical.
- **E2: rejected record:** residual-producing API returns `valid=False`. Both certificate and `ComputationResult` acceptance raise `ValidationError`.
- **E3: conditional record:** construct `ConditionalResult` from a conditional certificate with visible unchecked assumptions, then contrast its intentionally smaller interface with `ComputationResult`.
- **E4: serialization boundary:** show stable field ordering in JSON without claiming arbitrary diagnostic reconstruction.

Chapter 6: Errors, assumptions, and resource guards

> **Reference scope.** Chapter 6 is authoritative. This checklist distinguishes the frozen stable exception aliases from additional implementation-module classes and from built-in or third-party exceptions that remain observable on particular paths.

6.A Exception tiers and inheritance

- The frozen stable surface re-exports these seven package-specific classes: `KomorebiMathError`, `ValidationError`, `DimensionError`, `BackendUnavailableError`, `ExactnessError`, `AssumptionError`, and `ResourceLimitError`.
- `komorebi_math.exceptions` additionally defines `RelationError` and `FeatureNotImplementedError`. They belong to the implementation-module hierarchy but are not members of the frozen stable `__all__` list.
- The source inheritance graph is

  `KomorebiMathError`,

  `ValidationError` $\supset$ {`DimensionError`, `RelationError`, `ResourceLimitError`},

  `BackendUnavailableError`, `ExactnessError`, `AssumptionError`, `FeatureNotImplementedError`.

- `ValidationError` also inherits from the built-in `ValueError`. `FeatureNotImplementedError` also inherits from built-in `NotImplementedError`.
- Catching `KomorebiMathError` catches this package-specific hierarchy. It does not catch every exception observable from every public call.

6.B Guard maps and `CoordinateBudget`

- The guide uses these editorial guard classes:

$$
\begin{aligned}
&V : X \to X \cup \texttt{ValidationError},\\
&D : (\text{observed shape}, \text{required shape}) \to \{\checkmark, \texttt{DimensionError}\},\\
&H : (x, h) \to \{\checkmark, \texttt{AssumptionError}\},\\
&B : (request, limit) \to \{\checkmark, \texttt{ResourceLimitError}\}.
\end{aligned}
$$

- `[RESEARCH]` `CoordinateBudget` is a frozen, slotted record with defaults

$$(d_{matrix}, d_{poly}, h, n_{exact}) = (512, 512, 4096, 1{,}000{,}000).$$

- Its constructor rejects Boolean, non-integer, or nonpositive limits with `ValidationError`.
- `require_matrix(rows, columns, operation=...)` rejects negative dimensions with `ValidationError`. It raises `ResourceLimitError` when either dimension or the exact-entry product exceeds the declared budget.
- `require_degree(...)` and `require_horizon(...)` reject Boolean, non-integer, or negative requests with `ValidationError`, then use `ResourceLimitError` for an otherwise legal request above the configured maximum.

6.C Failure discipline

The decision rule is:

1. Reject malformed syntax, invalid scalar categories, and incompatible shapes before expensive work where the implementation supplies those guards.
2. Reject unmet preconditions with the most specific documented exception.
3. Apply an explicit resource budget before materializing a large exact object.
4. Return an invalid certificate when a legal computation completes but its post-computation identity or residual test fails.
5. Treat each source path as authoritative: not every public API normalizes every failure into this idealized sequence.

Resource limits are safety contracts. They are not numerical tolerances and do not authorize an approximation when a request is rejected.

6.D Construction-validation boundary

- `Settings.validate_on_construction` is a context-local default consulted by constructors that explicitly read it. It is not a universal switch applied automatically to every class in the package.
- Some constructors also expose a per-call `validate` argument. The function card for that constructor determines precedence and behavior.
- Disabling or deferring construction validation may make a failed certificate inspectable. It does not make an invalid mathematical relation valid, bypass later explicit `.require()` calls, or suppress unrelated Python exceptions.
- `FeatureNotImplementedError` identifies the package's deliberate planned placeholder path. An absent optional dependency instead uses `BackendUnavailableError` where the public adapter translates that condition.

6.E Built-in, third-party, and edge failures

- `ConditionalResult` constructed with nonconditional exactness raises the built-in `ValueError`.
- `register_backend` given an already registered name without `replace=True` raises the built-in `ValueError`.
- NumPy operations such as singular inversion may expose `numpy.linalg.LinAlgError` when the calling wrapper does not translate it.
- A third-party import or runtime may expose its own documented exception. The final function card records the actual boundary rather than promising a package-wide translation layer that does not exist.
- Negative sizes, ragged matrices, zero moduli, singular transforms, incompatible packet labels, and unavailable optional backends are distinct failures and require distinct examples.

6.F Example checklist

- **E0: dimensions:** legal matrix object plus incompatible vector shape. Observe `DimensionError` on the documented operation.
- **E1: assumptions:** execute one public precondition failure and preserve its actual exception class and message.
- **E2: resource:** budget dimension four, request a five-by-five exact matrix. Observe pre-materialization `ResourceLimitError`.
- **E3: certificate failure:** legal input reaches a residual check, returns an invalid certificate, and raises `ValidationError` only when acceptance is required.
- **E4: untranslated boundary:** singular NumPy inversion demonstrates why `KomorebiMathError` is not a universal catch-all.

Chapter 7: Public API tiers

Reference scope. Chapter 7 is authoritative. This checklist keeps structural API manifests, semantic fixtures, persistence contracts, and versioned-alias identity as separate evidence layers.

7.A Surfaces and source-faithful manifest records

- The research surface consists of the root and audited public domain namespaces. There is no required literal `komorebi_math.research` namespace.
- The curated beta surface is exported through `komorebi_math.beta`.
- The frozen compatibility surface is exported through `komorebi_math.stable`, with versioned aliases `komorebi_math.v1` and `komorebi_math.api.v1`.
- `PublicApiSymbol` has exactly the fields

$$M_{api} = (namespace, name, kind, implementation_module, qualname, signature).$$

- `PublicApiManifest` has the fields `package_version`, `namespaces`, `symbols`, `schema`, `schema_version`, and `stability_level`. Its digest is the SHA-256 of canonical JSON derived from those fields.
- Semantic fixtures are **not** fields of `PublicApiSymbol` or `PublicApiManifest`. Stable behavior is recorded in a separate committed semantic-fixture artifact.
- Portable codec identity and migrations are recorded in a separate persistence contract.

7.B Tier semantics

- `[STABLE]`: the frozen 1.x compatibility surface. Its contract covers the declared names and signatures plus separately qualified semantic and persistence behavior.
- `[BETA]`: a curated additive beta surface with strict signature comparison for its committed manifest. Evolution remains possible under beta release policy.
- `[RESEARCH]`: the broad current surface. Documentation remains source-faithful without silently promoting every symbol into a compatibility promise.
- API tier and mathematical evidence class are orthogonal. A stable function may return a numerical or conditional result. A research function may execute exact finite algebra.
- Re-export aliases receive one canonical implementation explanation and retain alias-specific import examples.

7.C Distinct verification layers

1. `check_stable_api()` loads the committed stable manifest, creates the current `komorebi_math.stable` manifest, and performs strict signature comparison.
2. `run_stable_semantics_fixture()` executes the separate committed stable behavior fixture.
3. `check_portable_codec_contract()` checks the separate codec and migration contract.
4. `check_stable_contract()` aggregates those structural, semantic, and persistence reports into one `StableContractReport`.
5. `run_stable_contract_verification()` additionally checks deterministic manifest regeneration and versioned stable namespace identity.

The stable manifest itself covers `komorebi_math.stable`. It does not by itself prove that `stable`, `v1`, and `api.v1` expose identical objects.

Versioned-alias evidence is the separate finite check

$$\begin{aligned} &\texttt{stable.__all__} = \texttt{v1.__all__} = \texttt{api.v1.__all__}, \\ \forall n: \quad &\texttt{getattr(stable,n)} \ \textbf{is} \ \texttt{getattr(v1,n)}, \\ &\texttt{getattr(v1,n)} \ \textbf{is} \ \texttt{getattr(api.v1,n)}. \end{aligned}$$

7.D Hypotheses and invariants

- Structural compatibility certifies the selected exported names, kinds, and signature text under the supported reflection policy. Its own certificate explicitly leaves behavioral and mathematical equivalence unchecked.
- Signature normalization absorbs supported interpreter representation differences without authorizing a callable-semantic change.
- A data symbol has no callable signature. Its value/type stability belongs to its documented semantic or persistence contract.
- Historical manifests remain migration evidence. They must not be described as the live `1.0.0b4` manifest.
- Stable alias identity is an API fact, not a claim that differently named mathematical concepts are interchangeable.

7.E Failure and edge cases

- Assuming every research symbol is beta or stable.
- Calling the root surface a literal `komorebi_math.research` namespace.
- Claiming semantic-fixture execution is part of a `PublicApiManifest` record.
- Claiming `api check --stable` alone proves semantic behavior, portable persistence, or versioned-alias identity.
- Duplicating prose for each stable alias and allowing those pages to drift.
- Treating historical version assertions or predecessor fixtures as current.
- Treating `__all__` order as mathematical meaning beyond an explicitly frozen compatibility record.

7.F Example checklist

- **E0: tri-alias identity:** import the frozen surface through all three paths. Compare `__all__`, object identity, and representative signatures.
- **E1: tier contrast:** place one stable symbol beside one research-only symbol while keeping mathematical exactness labels independent.
- **E2: structural check:** run `api check --stable` and inspect its manifest digests and zero drift fields.
- **E3: aggregate check:** run `verify stable` and distinguish structural, semantic, persistence, aggregate, and alias-identity checks.
- **E4: drift fixture:** compare a controlled mock manifest with one changed signature and report the exact failed field without mutating the shipped contract.

Chapter 8: Backends, scalar domains, and coercion

> **Reference scope.** Chapter 8 is authoritative. This checklist separates import presence, backend registry membership, backend selection, scalar-domain semantics, and hardware/runtime qualification.

8.A Core linear-algebra interface

- `LinearAlgebraBackend` is an abstract base class with data attributes `name` and `exact`, and these abstract methods: `as_matrix`, `as_vector`, `shape`, `zeros`, `eye`, `matmul`, `add`, `subtract`, `scale`, `transpose`, `adjoint`, `inverse`, `rank`, `norm`, `is_zero`, `column_stack`, `nullspace`, `kron`, and `copy`.
- Selection and discovery functions are

$$\begin{aligned}
\texttt{get_backend} &: \texttt{str | LinearAlgebraBackend | None} \to \texttt{LinearAlgebraBackend},\\
\texttt{register_backend} &: (\texttt{LinearAlgebraBackend}, \texttt{replace: bool}) \to \texttt{None},\\
\texttt{available_backends} &: () \to \texttt{dict[str,bool]},\\
\texttt{backend_name} &: \texttt{Any} \to \texttt{str}.
\end{aligned}$$

- The registry initially contains one `NumpyBackend()` under the name `"numpy"`.
- The annotation on `register_backend` is the public contract. Registration checks name collision but is not an exhaustive runtime conformance audit of every backend method.

8.B Presence, registry, selection, and qualification

- `get_backend(None)` selects NumPy. It does not consult `get_settings().backend` in this release.
- Passing an existing `LinearAlgebraBackend` instance to `get_backend` returns that instance.
- Requesting `"sympy"` lazily imports and registers `SympyBackend` when SymPy is installed. Otherwise it raises `BackendUnavailableError`.
- An unknown or currently unregistered name raises `BackendUnavailableError`.
- `register_backend` requires a unique name unless `replace=True`. A duplicate name raises built-in `ValueError`.
- `available_backends()` is a mixed import-presence probe with exactly these keys in this release:

$$\{\texttt{numpy}, \texttt{sympy}, \texttt{scipy}, \texttt{mpmath}, \texttt{cupy}\}.$$

  It is not a list of registered `LinearAlgebraBackend` instances. It does not probe JAX or PyTorch.
- `backend_name(value)` returns `"sympy"` only when the root defining module of `type(value)` is `sympy`. Every other value is classified as `"numpy"`. This is a lightweight heuristic, not universal dispatch.
- Import presence does not establish a working device, compatible runtime, numerical equivalence, or hardware qualification.

8.C Scalar-domain realizations and optional feature adapters

- `NumpyBackend` defaults to `dtype=np.complex128` for `as_matrix`, `as_vector`, `zeros`, and `eye`. This is a converter/constructor default, not a claim that every arbitrary ndarray supplied to every primitive is silently recast first.
- NumPy coercion of rational Python objects into the default array domain loses exact rational representation.
- `SympyBackend` uses SymPy matrices for exact symbolic rank, nullspace, inverse, and structural zero comparison.
- The `Fraction`-based exact coordinate layer used by `ExactCoordinateTransform` is independent of SymPy and remains available in the core installation.
- SciPy and mpmath are optional scientific/analytic dependencies, not core `LinearAlgebraBackend` implementations.
- JAX and PyTorch are optional directional-differentiation providers. They are not reported by `available_backends()` and are not core linear-algebra backend names.
- CuPy is an optional GPU execution dependency used by selected algorithm paths. Presence alone neither registers it as the core backend nor proves a working CUDA path.

8.D Numerical and exact operation rules

- NumPy zero testing uses

$$\text{is_zero}(A;\tau) \iff \text{np.linalg.norm}(A) \le \tau, \qquad \tau = 10^{-10} \text{ when omitted},$$

  where `np.linalg.norm` gives the Euclidean norm for a vector and the Frobenius norm for a matrix when no `ord` is supplied.
- NumPy `rank` delegates to `np.linalg.matrix_rank`. NumPy `nullspace` performs an SVD and, when tolerance is omitted, uses shape, floating epsilon, and the largest singular value to determine numerical rank.
- NumPy `transpose(A)` is `A.T`. `adjoint(A)` is `A.conj().T`.
- SymPy rank, nullspace, and zero testing ignore the numerical tolerance argument. Zero testing is structural equality with a zero matrix and does not promise a separate global simplification theorem.
- `SympyBackend.norm()` returns a Python float after numerical evaluation for a nonzero matrix, even though the backend's algebraic identity checks are exact.
- Core finite algebra, realization, seed, packet, operator, transfer, and morphism certificates use `backend.exact` to choose exact versus numerical certificate labeling on those implemented paths. Other domains retain their own producer-specific rules.

8.E Failure and edge cases

- SymPy absent. Unknown backend name. Duplicate registration.
- Malformed custom backend accepted by a non-exhaustive registry boundary and failing only when a missing or incompatible operation is called.
- Exact rational input coerced into NumPy and becoming numerical complex data.
- Near-singular numerical rank/nullspace changing with the tolerance rule.
- Singular NumPy inverse exposing `numpy.linalg.LinAlgError`.
- Symbolically equivalent but not structurally identical SymPy expressions requiring domain-appropriate simplification before a structural zero check.
- `backend_name` classifying an unfamiliar array/object type as NumPy.
- CuPy import succeeding while CUDA execution or device qualification fails.

8.F Example checklist

- **E0: NumPy core path:** select the default backend, materialize a matrix, inspect dtype, rank, adjoint, nullspace, and one numerical zero residual.
- **E1: exact/numerical mirror:** use the same rational nilpotent matrix through NumPy and optional SymPy. Preserve numerical versus exact certificate labels.
- **E2: rank boundary:** $A_\varepsilon = \operatorname{diag}(1, \varepsilon)$. Vary the numerical tolerance without claiming exact singularity.
- **E3: adjoint boundary:** complex matrix with $A^T \neq A^* = \overline{A}^T$.
- **E4: lazy optional failure:** request SymPy only after inspecting presence. If absent, retain `BackendUnavailable Error` while proving NumPy remains usable.
- **E5: feature-adapter boundary:** distinguish SciPy/mpmath/JAX/Torch/CuPy feature availability from the core linear-algebra registry and from hardware qualification.

Part III: Operator, packet, and refinement foundations

Chapter 9: Typed operator grammars

> **Reference scope.** Chapter 9 is authoritative for construction, composition, realization, relation validation, executable examples, and invalid paths. This retained card is the source-based specification. Paths remain formal typed words rather than quotient classes. Arrow names must be unique, while repeated vertex inputs are normalized by first occurrence. `Relation Residual` is available from the core and stable namespaces but is not a package-root export.

9.A Notation, maps, and definitions

- `Arrow(name,source,target)` realizes $a : X \to Y$. `OperatorWord(arrows,source,target)` stores arrows in application order.
- `OperatorGrammar.word(self, *arrow_names: str, vertex: str | None = None) -> OperatorWord` realizes $(a_1, \dots, a_k) \mapsto w : X_0 \to X_k$, valid when $t(a_j) = s(a_{j+1})$. `vertex` specifies the empty word's object.
- Identity is the empty word 1_X. A relation is `OperatorRelation(name, terms)`:

$$R = \sum_w c_w w : X \to Y.$$

- `OperatorRealization` supplies dimensions d_X and matrices $\rho(a) \in \mathbb{F}^{d_{t(a)} \times d_{s(a)}}$:

$$\rho(a_1 \cdots a_k) = \rho(a_k) \cdots \rho(a_1), \qquad \rho(1_X) = I_{d_X}.$$

- Reference cards: grammar properties and `arrow`, `identity`, `word`, `relation`, `add_relation`, `paths`. Realization `evaluate`, `relation_matrix`, `relation_residuals`, `relation_certificate`, `path_operators`, `loop_operators`. `RelationResidual`.

9.B Hypotheses, invariants, and certificates

- Vertex and arrow names are nonempty. Repeated vertex inputs are silently deduplicated in first-occurrence order, while arrow names must be unique. Relation terms are nonempty and parallel.
- Realization space keys equal grammar vertices. Operator keys equal arrows. Every matrix has the typed shape.
- `[EXACT]` relation iff $\rho(R) = 0$. `[NUMERICAL]` relation iff $\|\rho(R)\| \le \tau$.
- `relation_certificate()` records theorem `PSC-I-T01`. Constructor can raise `RelationError` immediately when `validate_relations=True`.
- `paths(max_length=L)` enumerates typed paths and does not quotient by declared relations.

9.C Failure and edge cases

- Empty word without `vertex`, noncomposable arrows, nonparallel relation, missing/extra realization key, wrong matrix shape, failed declared relation.
- `word(a,b)` realizes as BA, not AB.

9.D Example checklist

- **E0:** $X \xrightarrow{a} Y \xrightarrow{b} Z$. Assert $\rho(ab) = BA$, enumerate paths through length two.
- **E1:** one loop T with $T^3 - T = 0$. Inspect zero relation matrix and `PSC-I-T01`.
- **E2:** exact nilpotent $N^2 = 0$ under SymPy and numerical mirror under NumPy.
- **E3:** attempt $b + a$ with unequal endpoints. Expect `RelationError`.

Chapter 10: Operator algebras and seed systems

> **Reference scope.** Chapter 10 is authoritative for finite algebra closure, seed hulls, presentations, bounded standard-seed search, and seed-rank formulas. This retained card is the source-based specification. `OperatorAlgebra` is unital by default but supports `include_identity=False`. `SeedSystem` requires at least one seed but permits an empty operator family. `AlgebraBasisResult` is a public record in this release, but no documented routine is presented as returning it.

10.A Notation, maps, and algorithms

- Generated algebra:
$$\mathcal{A} = \operatorname{span}\{I, A_i, A_iA_j, ...\} \subseteq M_n(\mathbb{F}), \qquad \dim \mathcal{A} \le n^2.$$
- `OperatorAlgebra(generators, *, backend=None, tolerance=None, include_identity=True)` closes a rank-increasing basis under pairwise multiplication. `basis`, `dimension`, `contains`, `certificate`, `seed_system`, `transfer_graph`.
- `matrix_units(n)` returns E_{ij} in row-major order with $E_{ij}E_{k\ell} = \delta_{jk}E_{i\ell}$.
- For seeds S, `SeedSystem` computes breadth-first rank-increasing orbit closure:
$$\mathcal{H}(S) = \operatorname{span}\{As : A \in \mathcal{A}, s \in S\}.$$
- Cover `hull_vectors`, `hull_basis`, `hull_dimension`, `is_generating`, `generation_certificate`, `orbit_layers`, `presentation`, `minimum_standard_basis_seeds`, `cyclic_span`, and rank-bound functions.

10.B Hypotheses, invariants, and certificates

- Generators are nonempty same-size square matrices. Seeds share ambient dimension.
- Algebra `PSC-I-D05` checks generator inclusion, basis independence, and multiplicative closure. It checks identity inclusion only when `include_identity=True`.
- Seed `PSC-I-T02` is valid iff $\dim \mathcal{H}(S) = n$. `FreePresentation` records evaluation map, kernel, rank, domain/-codomain dimensions.
- Exact formulas:
$$r_{ss} = \max_i \lceil m_i/d_i \rceil, \quad \max_i r_i \le r_{shared} \le \sum_i r_i, \quad r(V \otimes W) \le r(V)r(W).$$

- `single_operator_seed_rank` requires the `exact` SymPy dependency and a square matrix whose entries convert into `sympy.QQ`. It computes $\max_p \operatorname{nullity}(p(T))/\deg p$.

10.C Failure and edge cases

- Non-square/mixed-size generators. Empty family. Incompatible seed dimension. Missing SymPy or single-operator entries that do not convert into `sympy.QQ`.
- Standard-basis subset search is exponential and guarded above dimension 12 unless `force=True`.

10.D Example checklist

- **E0:** construct `matrix_units(2, backend="sympy")` and `OperatorAlgebra(..., backend="sympy")`. $\{E_{ij}\}_{i,j<2}$ generates M_2, with dimension four and exact closure. With the default NumPy backend the same closure certificate is numerical.
- **E1:** a 3×3 Jordan block generates span$\{I, J, J^2\}$. One cyclic seed yields three orbit layers.
- **E2:** diagonal action with a coordinate seed. Compute positive hull codimension and failed generation certificate.
- **E3:** compare shared direct-sum bounds, independent sum rank, and tensor upper bound for $(r_1, r_2) = (2, 3)$.

Chapter 11: Packet systems and transfer blocks

Reference scope. Chapter 11 is authoritative for packet coordinates, ambient transfer blocks, graph/path orientation, support preorders, and validated morphisms. This retained card is the source-based specification. Blocks use target-by-source indexing while graph adjacency uses source-by-target indexing. Algebraic and Hilbert certificates remain separate. `TransferPath` is available from its domain and stable namespaces rather than the package root.

11.A Notation, maps, and defining equations

- `PacketSystem(P_0,...,P_{r-1})` and embedded `PacketCoordinates`:

$$P_i^2 = P_i, \quad P_i P_j = 0\ (i \neq j), \quad \sum_i P_i = I, \quad \mathcal{A}_P(x) = (P_i x)_i, \quad \mathcal{S}_P(c) = \sum_i c_i.$$

- Cover packet `analyze`, `synthesize`, `support`, `packet_dimensions`, `aggregate`, `tensor`, `dual`, `equivalent`, `transport`, `restrict`, `quotient`, `block_diagonal_projection` and coordinate access/reconstruction.
- `PacketOperator.from_operator(operator, source, target=None) -> PacketOperator` stores ambient blocks (with `target=source` when omitted)

$$T_{ji} = Q_j T P_i, \qquad T = \sum_{j,i} T_{ji}, \qquad (ST)_{ki} = \sum_j S_{kj} T_{ji}.$$

- Cover reconstruct/apply/coordinate apply, compose, adjoint, tensor, power, norms, diagonal test, support mask.
- `TransferGraph` uses adjacency `[source][target]`. `TransferPath` and

$$(T^\ell)_{ba} = \sum_{\pi: a \to b, |\pi| = \ell} T_\pi$$

  are implemented by `path_contributions` and `block_from_paths`.
- `SupportPreorder` requires a nonempty square reflexive-transitive relation. It computes mutual-reachability classes, the strict class graph, and the corresponding strict-ideal nilpotency bound.

11.B Hypotheses, invariants, and certificates

- Algebraic packet `PSC-I-T20` checks idempotence, annihilation, completeness. `hilbert_certificate` separately checks $P_i = P_i^*$.
- Packet-operator `PSC-I-T27` checks that reprojected reconstruction equals every stored block.
- Path sum returns `ComputationResult` with `PSC-I-T29` exact/numerical comparison to `power(length)`.
- Aggregation groups partition indices exactly once. Restriction requires $RJ = I$ and invariance. Quotient requires $QS = I$ and compatibility.
- Validated operator, packet, and seed morphism factory routes enforce $\Phi A = A'\Phi$ and the declared packet/seed image laws. Direct dataclass construction does not perform those checks.

11.C Failure and edge cases

- Oblique packets can pass algebraic certification and fail Hilbert certification.
- `PacketSystem.dual()` transposes packet matrices. It is not the conjugate-adjoint operation used by Hilbert certification.
- Coordinates tied to another system. Nonpartition aggregation. Nonendomorphism powers/paths. Negative power/length. Support-mask orientation reversal.

11.D Example checklist

- **E0:** three coordinate packets, sparse T, reconstruct and apply via blocks.
- **E1:** diamond graph with two length-two paths. Show both ordered products sum to $(T^2)_{30}$.
- **E2:** aggregate $1 + 1 + 1$ packets to $2 + 1$. Reflect support and certify packet morphism.
- **E3:** construct an exact oblique decomposition $P_0 + P_1 = I$ with `backend="sympy"`. Contrast `certificate()` with failed `hilbert_certificate()`.

Chapter 12: Refinement towers

> **Reference scope.** Chapter 12 is authoritative for adjacent and multilevel refinement, common refinements, weighted transfer expansions, and linear refinement defects. This retained card is the source-based specification. Weighted paths are retained only when their total weight is strictly below the requested precision. Exact p-adic qualification and conditional numerical qualification are intentionally distinct.

12.A Notation, maps, and algorithms

- `PacketRefinement(coarse=P, fine=Q, parent_of_fine=p)` encodes

$$P_a = \sum_{b:p(b)=a} Q_b.$$

- Coordinate maps:

$$c_a = \sum_{b:p(b)=a} f_b, \qquad f_b = Q_b \sum_a c_a.$$

- Cover `children`, `parent`, `certificate`, `coarsen`, `refine`, operator conversions, and `support_reflection`.
- `RefinementTower(R_0,...,R_{L-1})` supplies ordered `levels`, multilevel refine/coarsen, `descendant_address`, and the adjacent-level tower certificate.
- `common_refinement(P,Q)` uses products of commuting projectors $R_{ab} = P_a Q_b$, removes zero packets, and returns refinements back to both parents.
- `LinearRefinementDefect` records $\Delta = CT_f - T_c C$ and implements power, polynomial, resolvent, exponential/-Duhamel, and multilevel propagation identities.

- `WeightedTransferGraph` stores $T = D + \sum_e E_e$, positive weights $w(e)$, supported edges, weighted paths, and the filtered inverse

$$T^{-1} = D^{-1} + \sum_{\pi \neq \emptyset} (-1)^{|\pi|} A_\pi D^{-1}, \qquad A_e = D^{-1} E_e,$$

truncated to $w(\pi) < q$. Reference `WeightedTransferEdge`, `WeightedPath`, `FilteredInverseExpansion`, path/minimum-weight methods, acyclic exact inverse, and transfer-series matrices.

12.B Hypotheses, invariants, and certificates

- Coarse/fine systems share backend and ambient dimension. Each fine packet has one valid parent. Every coarse packet has a child.
- Adjacent tower endpoints are equivalent. Each local refinement has `PSC-II-T03`. Coordinate maps and tower checks retain exact/numerical status.
- Common refinement requires commuting projectors, checked exactly or at tolerance.
- Defect identities compare finite matrix expressions. Zero defect means exact intertwining $CT_f = T_c C$, not equality of the spaces.
- Weighted transfer requires packet-diagonal invertible D, exact source/target edge support, and positive weights. Enumeration retains paths with $w(\pi) < q$ and enforces the declared `max_paths` guard. With exact SymPy plus prime p, the omitted inverse error is certified by p-adic valuation. Otherwise the filtration conclusion remains conditional, even when the evaluated operator happens to be nonsingular.

12.C Failure and edge cases

- Missing child, invalid parent index, endpoint mismatch, coordinates from wrong level, reverse level order, non-commuting common-refinement inputs, invalid edge support, singular diagonal, or weighted-path explosion beyond `max_paths`.
- A zero product packet is omitted. Generated common-refinement names therefore need not form a full Cartesian list.

12.D Example checklist

- **E0:** four fine coordinate packets grouped into two coarse packets. Refine/coarsen one vector and reflect support.
- **E1:** three levels $P^{(0)} \prec P^{(1)} \prec P^{(2)}$. Compare tower refinement with direct finest-level analysis of the reconstructed vector.
- **E2:** acyclic weighted chain $0 \to 1 \to 2$ on the SymPy exact backend. Compare the finite path inverse with the ordinary exact inverse and inspect omitted weight at precision q.
- **E3:** choose C, T_c, T_f with nonzero Δ. Verify the implemented $k = 2$ propagation identity.

Chapter 13: Residue, CRT, lattice, and Smith coordinates

Reference scope. Chapter 13 is authoritative for the finite residue, nested-address, CRT, rational lattice, gluing, valuation-delay, and Smith-congruence contracts. This retained card is a source-verified checklist. It preserves the SymPy-only lattice/Smith boundary and the narrower portable-codec surface.

13.A Notation, maps, and defining equations

- Residue analysis:
$$x_r[k] = x[r + Mk], \qquad x[n] = x_{n \bmod M}[\lfloor n/M \rfloor].$$
Cover `ResidueCoordinates`, analyze/synthesize/nested/refine/coarsen, residue packet systems, nested address $a = r + Ms$, and packet-coordinate bridge.
- CRT address for pairwise-coprime (m_i):
$$x \equiv r_i \pmod{m_i}, \qquad 0 \le x < \prod_i m_i.$$
Cover `CRTAddress`, `crt_pair`, `crt_many`, `factor_residue`, `dyadic_odd_factor`.
- `LatticePacketData(lattice_basis, projectors, *, prime: int, split_basis=None)` moves rational projectors into lattice coordinates $B^{-1}P_\alpha B$. Denominator weights use
$$w_\alpha = \max(0, -\min_{ij} v_p((B^{-1}P_\alpha B)_{ij})).$$
- Cover `GluingModule`, `PrecisionDelay`, integral separation, gluing quotient invariants, refinement parent data, and `refinement_weight_monotonicity`.
- `SmithDecomposition` and `SmithCongruenceProblem(matrix, rhs, *, prime: int, depth: int)` reduce $Ax \equiv b \pmod{p^k}$ through Smith coordinates. Cover solution obstruction, count, particular solution, and enumeration guard.

13.B Hypotheses, invariants, and certificates

- Residue modulus is positive. Channels may be ragged but must have exact expected lengths.
- CRT component moduli are positive and pairwise coprime. Nested residue composition does not require coprimality and is a different construction.
- Lattice basis is invertible over $\mathbb{Q}$. Prime arguments are prime. Valuation uses $v_p(0) = \infty$.
- Smith decomposition supplies unimodular transforms and diagonal divisibility through the SymPy reduction. Its certificate directly checks (LAR=D). Congruence solution records solvability, obstructions, solution count, and exact modular verification.
- Portable refinement records reject extra/missing fields. Codec envelopes reject malformed data and digest tampering.

13.C Failure and edge cases

- Noncoprime CRT moduli, zero/negative modulus, bad channel length, singular lattice basis, composite "prime", large exact-arithmetic cost, inconsistent congruence, and guarded or expensive enumeration.
- Signed Smith diagonal entries must be normalized correctly. Preserve the regression $-2x = 2 \pmod 8 \Rightarrow x \in \{3, 7\}$.

13.D Example specifications

Chapter 13 presents these four worked examples. Their symbolic statements remain here as compact reference requirements.

- **E0:** split `range(17)` modulo five, display ragged lengths, synthesize exactly.
- **E1:** `crt_pair(1,4,2,3)` gives 5 mod 12. Contrast nested address with the same integers.
- **E2:** compute $v_2(3/8) = -3$, projector weights, and a precision-delay record.
- **E3:** $A = \mathrm{diag}(2, 4, 0)$, modulus 8. Derive transformed divisibility conditions and solution count.

Chapter 14: Polyphase systems and refinement

Reference scope. Chapter 14 is authoritative for signal, residue, arithmetic, tower, and lattice polyphase refinement. This retained card remains the finite-law and example checklist. It does not introduce a lattice tower or an infinite refinement limit.

14.A Notation, maps, and algorithm

- `PolyphaseCoordinateRecord` is `PolyphaseCoordinates | ResidueCoordinates | ArithmeticPolyphase`.
- `PolyphaseRefinement(M,N)` requires $M \mid N$, $K = N/M$, and implements

$$a = r + Ms, \quad r = a \bmod M, \quad s = \lfloor a/M \rfloor, \quad (x_r^{(M)})_s^{(K)} = x_{r+Ms}^{(N)}.$$

- Refinement slices parent channel `r` by `s::K` without reconstructing the ambient signal. Coarsening interleaves children.
- Cover address/split/parent/child/children/parent-map, refine/coarsen, `certified_refine`, certificate, compose, local JSON, and convenience functions.
- `PolyphaseRefinementTower(orders: tuple[int, ...])`, with $M_0 \mid \cdots \mid M_L$, implements

$$a_L = r + \sum_{j=0}^{L-1} M_j s_j$$

  plus descendants, path address, direct refinement, and sequential/direct coherence.
- `LatticePolyphaseRefinement(coarse_strides: tuple[int, ...], fine_strides: tuple[int, ...])` applies the same law componentwise, with Cartesian child digits and channel counts $\prod_j M_j, \prod_j N_j$.

14.B Hypotheses, invariants, and certificates

- Orders/strides are positive integers, `bool` rejected. Dimensions agree. Every coarse component divides its fine component.
- `KM-B15-T01` checks coarsen-after-refine and equality with direct fine analysis. Exact integer/rational paths are exact. Floating/complex paths use a scaled tolerance.
- `KM-B15-T02` checks tower sequential versus direct refinement. `KM-B15-T03` is the lattice analogue.
- Composition requires matching middle order/strides. Local schemas contain exact field sets and version 1.

14.C Failure and edge cases

- Nondivisible orders, malformed digits/addresses, wrong record order, inconsistent child lengths/shapes, mismatched tower level, extra schema field.
- `copy=False` may permit sliced NumPy views but does not promise view semantics for coarsening allocations.

14.D Example specifications

Chapter 14 presents the four examples through address tables, direct-fine comparisons, a tower certificate, and a lattice roundtrip.

- **E0:** Ref$(2, 8)$, $(r, s) = (1, 3) \leftrightarrow a = 7$. Print full address table.
- **E1:** integer residue data length 31, $4 \to 12$. Compare refined channels to direct modulus-12 analysis and coarsen exactly.
- **E2:** tower $(2, 6, 24)$. Compare adjacent execution and direct address map under `KM-B15-T02`.
- **E3:** lattice array shape $(6, 9)$, strides $(2, 3) \to (4, 9)$. Certify componentwise roundtrip.

Part IV: Coordinate calculus and analysis-synthesis systems

Chapter 15: Coordinate objects

> **Reference scope.** Chapter 15 is authoritative for dense exact rational conventions, finite bases, atlas routing, explicit budgets, exact solves, and affine and barycentric objects. The retained card is the source-based specification.

15.A Notation, types, and definitions

- Exact layer: `Scalar=int|Fraction`, `Vector=tuple[Fraction,...]`, `Matrix=tuple[tuple[Fraction,...],...]`, `Polynomial=tuple[Fraction,...]` with ascending powers.
- `FiniteBasis(B)` has columns b_j, synthesis $x = Bc$, exact analysis by solve, Gram $G = B^T B$, square-basis dual rows $L = B^{-1}$, and the rectangular-span projector $P = B(B^T B)^{-1} B^T$.
- `CoordinateSystem(name,dimension,kind,description)` and directed `CoordinateAtlas` with shortest resolved path transform. `AtlasPath.length`. `CommutingDiagramCheck` compares products.
- Exact linear-algebra cards cover normalization, shape, zero and identity constructors, transpose and column operations, addition, subtraction, multiplication, vector multiplication, powers, Kronecker products, RREF, rank, determinants, inversion, solving, nullspaces and `ExactLinearSystem`.
- Basis constructors: standard, matrix columns, direct sum, tensor product, permutation, scaling. `CoordinateBudget.require_*` guards dimension, degree, horizon, and exact-entry count.

15.B Hypotheses, invariants, and failures

- Rows are rectangular and dimensions legal. Basis vectors are independent. Square analysis requires invertibility. Rectangular analysis requires exact membership.
- `FiniteBasis.certificate()` proves independence and stated finite basis properties. Atlas path validity requires matching endpoint labels and dimensions. Path comparison certificate records the exact matrix difference.
- Reject ragged/empty-invalid matrices, singular inverse, inconsistent system, vector outside a rectangular span, duplicate atlas system/edge without replacement, disconnected route, and exceeded budget.

15.C Example specifications

E0 and E1 are executed exactly in Chapter 15. E2 is presented as a derived guide example built from the shipped atlas API. Its perturbed edge is not a separate shipped example file.

- **E0:** solve underdetermined $Ax = b$. Display particular x_0, nullspace N, and $x = x_0 + Nz$. Then show an inconsistent system residual.
- **E1:** plane basis in $\mathbb{Q}^3$. Compute Gram matrix and P, verify $P^2 = P$, test membership, and show that `dual_rows()` is square-basis-only.
- **E2:** atlas $A \to B \to C$ versus $A \to D \to C$. Compare products, then perturb one edge for a noncommuting diagnostic.

Chapter 16: Exact and numerical coordinate transforms

> **Reference scope.** Chapter 16 is authoritative for the exact, numerical, affine, formal, normalized, polynomial-operator, shift, realization, modular, persistence, and stable numerical analysis/synthesis contracts. This card remains the compact completion checklist.

16.A Typed maps and equations

- `CoordinateTransform(source: str, target: str, matrix: Matrix, theorem: str, description: str = '')` and its `ExactCoordinateTransform` alias implement $c_t = Tc_s$, inverse T^{-1} when available, and `then(U)` as UT. `certificate()` validates the finite rational transform object and reports square/determinant/invertibility diagnostics. `roundtrip_valid()` separately checks exact two-sided inversion.
- `NumericCoordinateTransform` mirrors the map over NumPy with tolerance and condition number. `FiniteFieldCoordinateTransform` acts in $\mathbb{F}_p$. Rational reduction sends $a/b \mapsto ab^{-1} \pmod p$ only when $p \nmid b$.
- Affine maps: $y = Ax + b$, $(B, c) \circ (A, b) = (BA, Bb + c)$, homogeneous matrix $\begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix}$. Barycentric coordinates satisfy $x = \sum_i \lambda_i v_i$, $\sum_i \lambda_i = 1$.
- Formal jet $\phi(t) = a_1 t + \cdots + a_N t^N$ has $a_1 \neq 0$. Cover truncated composition, inversion, pullback/pushforward, and substitution transform.
- Coordinate calculus compiles polynomial rules columnwise. Include derivative, integral, multiplication, affine substitution, finite difference, transport, composition, and $[A, B] = AB - BA$.
- Normalization sends $F = \sum a_n z^n/\gamma_n = \sum b_n z^n/\eta_n$ to $b_n = (\eta_n/\gamma_n)a_n$. Shift-polynomial Bézout uses $u(L)p(L) + v(L)q(L) = I$ on the common finite interior.

16.B Hypotheses, invariants, and failures

- Labels/dimensions compose. Inverse availability requires a square nonsingular matrix. Numerical validity uses residual/tolerance and records conditioning. Modular prime must be prime and denominators invertible.
- Affine matrix is square, simplex vertices affinely independent, formal constant term is zero and linear coefficient nonzero, polynomial degree/horizon remains within budget.
- Singular `CoordinateTransform`, `NumericCoordinateTransform`, and `FiniteFieldCoordinateTransform` objects are representable, but inverse calls fail and square-map diagnostics/certificates report noninvertibility or invalidity as defined by each class. `AffineCoordinateTransform` rejects a singular linear part at construction. Also reject ill-shaped inputs, label mismatch, degenerate simplex, noninvertible modular denominator, composite modulus, noncomposable jets, over-truncation, noncoprime shift polynomials, and finite-horizon boundary misuse.

16.C Example specifications

The exact composition, barycentric, finite polynomial-calculus, and modular obstruction targets are all resolved in the published chapter. The chapter also records advanced edge cases that the four compact example specifications do not enumerate.

- **E0:** exact $A \to B \to C$. Verify `then` order and $(UT)^{-1} = T^{-1}U^{-1}$.
- **E1:** triangle barycentrics including one point with a negative weight. Distinguish affine validity from convex membership.
- **E2:** transport D and M_x into falling-factorial coordinates. Verify $[D, M_x] = I$ only on a safe truncated subspace.
- **E3:** reduce rational shear modulo seven, then choose a denominator divisible by seven and expect obstruction.

Chapter 17: Polynomial and classical coordinate families

> **Reference scope.** Chapter 17 is authoritative for exact polynomial storage, graded and finite bases, the classical catalog, Bell/Touchard ownership boundaries, connection maps, budgets, persistence, failures, examples, and current verification evidence. This retained card is the compact contract checklist.

17.A Families, maps, and equations

- `PolynomialFamily(name,rule)` supplies $P_n(x)$ and coefficient matrix $M_P = [P_0 \cdots P_N]$. Connection:

$$C_{Q\leftarrow P} = M_Q^{-1} M_P, \qquad p_n = \sum_k (C_{Q\leftarrow P})_{kn} q_k.$$

- Cover exact polynomial add/scale/shift/multiply/evaluate/derivative, monomial/Fibonacci/Euler constructors, Euler-to-Fibonacci coefficients/transform, companion powers, derivative operators, operator conjugation, and secant-Euler recovery.
- Catalog cards cover falling/rising factorial, binomial, Bernoulli, Euler, Fibonacci, Lucas, Pell, Chebyshev T/U, Legendre, Hermite variants, Laguerre, custom Appell, Bernstein, Newton, and Lagrange.
- Interpolation maps: evaluation $c \mapsto (p(x_i))_i$, inverse interpolation when nodes are distinct. Affine substitution sends $p(x) \mapsto p(ax+b)$.

17.B Hypotheses, invariants, and failures

- A degree-N family must yield exactly graded independent columns through N. Connections are exact and invertible within the finite degree budget.
- Operator transport obeys $L_Q = CL_PC^{-1}$. Bernstein basis obeys $\sum_{k=0}^{n} B_{n,k}(x) = 1$.
- Family connections return `CoordinateTransform` and its exact certificate. Elementary polynomial/scalar helpers return raw exact tuples or integers rather than separate certificates.
- Reject negative degree/index, index beyond Bernstein degree, duplicate interpolation nodes, insufficient Appell initial values, nongraded custom family, singular connection, and exceeded polynomial budget.

17.C Example checklist

Chapter 17 presents these four targets, each as an executable guide path or a source-verified contract example with its exactness boundary stated.

- **E0:** expand $E_n(x)$ in graded Fibonacci polynomials through $n = 6$. Reconstruct every polynomial exactly.
- **E1:** Legendre $\leftrightarrow$ Chebyshev connection and transported derivative matrix.
- **E2:** interpolate rational samples in Newton and Lagrange bases. Synthesize the same polynomial.
- **E3:** verify Bernstein partition of unity and reject repeated interpolation nodes.

Chapter 18: Combinatorial, recurrence, and state-space coordinates

> **Reference scope.** Chapter 18 is authoritative for exact combinatorial maps, forward differences, recurrence defect coordinates, realization and state-space transport, persistence, failures, examples, and verification evidence. It also records the shipped `RecurrenceModel.synthesize()` convenience-method defect without hiding the fully operational lower-level synthesis path.

18.A Typed transforms and defining equations

- Triangular transforms include Stirling/Lah, binomial, forward difference, divisor/subset zeta and Möbius inverses:

$$\Delta^n a_0 = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} a_k, \quad b_n = \sum_{d|n} a_d, \quad b_S = \sum_{T\subseteq S} a_T.$$

- Recurrence coordinates for $a_{n+d} = \sum_{i<d} c_i a_{n+i} + \delta_n$ are $(a_0, \ldots, a_{d-1}, \delta_0, \ldots)$. Analysis is unit lower triangular and synthesis is exact.
- Cover recurrence polynomial, companion, defect, analysis/synthesis transforms, records, cross-model change, Green weights, variation of constants, named models/catalog, and Euler-to-Fibonacci path.
- Realization $x_n = A^n x_0$, $a_n = c^T x_n$. Observability $O_h = [c^T; c^T A; \ldots]$, Krylov $K(A, v) = [v, Av, \ldots]$, intertwiners solve $BS = SA$.
- State space: $x_{k+1} = Ax_k + Bu_k$, $y_k = Cx_k + Du_k$, and under $z = Tx$, $(A', B', C', D') = (TAT^{-1}, TB, CT^{-1}, D)$.

18.B Hypotheses, invariants, and failures

- Transform sizes and recurrence horizons respect budget. Recurrence prefix length is at least the order. State recovery uniqueness requires rank $O_h = d$.
- State-coordinate certificate compares Markov parameters $H_0 = D$, $H_k = CA^{k-1}B$. Cyclic similarity requires invertible Krylov matrices.
- Subset zeta grows as 2^r. Reject undersized prefixes, unknown model, nonobservable/noncontrollable canonical transform, noncyclic vectors, dimension mismatch, and budget overflow.

18.C Example checklist

Chapter 18 presents these four targets. They remain here as reference requirements.

- **E0:** squares $(0, 1, 4, 9, ...)$ to forward differences. Recover by inverse Newton evaluation.
- **E1:** arbitrary length-18 sequence in Fibonacci defect coordinates. Reconstruct and inspect homogeneous versus defect parts.
- **E2:** Euler prefix analyzed by Fibonacci recurrence, yielding the shipped exact reconstruction path.
- **E3:** SISO companion model before/after T. Assert identical finite Markov parameters and show nonunique recovery at insufficient horizon.

Chapter 19: Spectral, packet, tensor, and operator transport

> **Reference scope.** Chapter 19 is authoritative for numerical spectral systems, exact packet permutations, tensor and variance-aware transport, certificates, persistence, dense cost models, worked paths, and failures. Its digit-reversal contract explicitly requires radix at least two because the shipped radix-one path does not terminate for lengths greater than one.

19.A Maps and equations

- Numeric transforms: unitary DFT $F_{kn} = N^{-1/2}e^{-2\pi ikn/N}$, orthonormal DCT-II, Sylvester Walsh-Hadamard, dyadic Haar, and modal $V^{-1}AV \approx \mathrm{diag}(\lambda)$.
- Exact packet permutations cover residue-class order, fixed-width digit reversal, tensor-axis permutation, CRT tuple order, and stable key sorting. Each order induces a permutation `CoordinateTransform`.
- Variance-aware transport for $y = Tx$:

$$v' = Tv, \quad \phi' = T^{-T}\phi, \quad A' = TAT^{-1}, \quad G' = T^{-T}GT^{-1}.$$

- Rectangular maps use $A' = T_c A T_d^{-1}$. Tensor and direct-sum transforms use Kronecker and block diagonal products. Pairing invariant: $\phi'(v') = \phi(v)$.

19.B Hypotheses, invariants, and failures

- Numeric matrices have finite entries and compatible dimensions. Walsh/Haar size requirements are enforced by constructors. Modal coordinates require a numerically complete eigenvector basis under `np.linalg.matrix_rank(eigenvectors, tol=tolerance)`.
- Permutations cover each index exactly once. CRT moduli are pairwise coprime. Digit-reversal length has the required radix width. Tensor axes are a permutation.
- Variance list length equals tensor rank. Exact tensor/variance helpers operate on rational `CoordinateTransform` objects and return raw exact `Vector` or `Matrix` values. `pairing_invariant` returns `bool`. Transform-object certificates come from `CoordinateTransform.certificate()` or `NumericCoordinateTransform.certificate()`. The raw transport helpers return no separate certificate.
- Reject rank-deficient modal eigenvector systems at the declared tolerance, nonfinite input, invalid radix length, noncoprime CRT moduli, repeated axis, covariance mismatch, or a noninvertible transform where an inverse is required. The modal synthesis condition number is diagnostic rather than a separate constructor rejection threshold.

19.C Example checklist

Chapter 19 presents these four targets. They remain here as reference requirements.

- **E0:** DFT and Haar roundtrips. Compare $\|F^*F - I\|$ and energy residuals.
- **E1:** bit reversal and residue grouping for length eight. Display order and exact permutation inverse.
- **E2:** transport vector/covector/operator/form by one rational T. Certify pairing and quadratic-form invariance.
- **E3:** diagonalizable $A = V\Lambda V^{-1}$ versus a defective Jordan block rejection.

Chapter 20: Analysis-synthesis and redundant frames

> **Reference scope.** Chapter 20 is authoritative for numerical and exact analysis/synthesis systems, canonical duals, redundant components, gauges, lifts, bridges, coefficient blocks, adjoints, persistence, costs, failures, examples, and current verification evidence. The retained card is the finite contract checklist.

20.A Typed systems, maps, and equations

- A mathematical analysis/synthesis system has

$$A : X \to K, \quad S : K \to X, \quad SA = I_X.$$

  `ExactAnalysisSynthesisSystem(A,S)` enforces this identity during construction. Bare numerical `AnalysisSynthesisSystem(A,S)` validates shape, finiteness, labels, and tolerance but may be constructed with $SA \neq I_X$. Its `certificate()` then has `valid=False`. Numerical `canonical_dual` first applies a relative-SVD full-column-rank test, computes `np.linalg.pinv(A, rcond=tolerance)`, constructs the system, and requires its certificate. The exact finite identity is $S = (A^*A)^{-1}A^*$ for full-column-rank A.
- Coordinate selection E_I yields physical component $C_I = SE_IA$, with $\sum_I C_I = I$ for a partition. Operator blocks are $C_\beta T C_\alpha$.
- Gauge algebra: $P = AS$, $Q = I - P$, $c = Pc + Qc$, $Qc \in \ker S$, and $c \sim d \iff S(c - d) = 0$.
- Physical map lift $\widehat{T} = A_Y T S_X$ satisfies $P_Y \widehat{T} P_X = \widehat{T}$ and $S_Y \widehat{T} A_X = T$. Mismatched composition uses bridge $R = A_{Y,in} S_{Y,out}$.
- Reference all methods of `AnalysisSynthesisSystem`, `AnalysisSynthesisBlocks`, `CoefficientPartition`, numerical/exact gauge systems, maps, coefficient blocks, direct sums, tensor products, adjoints, dual adjoints, reblocking, and physical-block recovery.

20.B Hypotheses, invariants, and certificates

- Shapes are $A \in \mathbb{F}^{m\times n}$, $S \in \mathbb{F}^{n\times m}$, $m \geq n$ for canonical dual. Partitions cover coefficient indices exactly once.
- System certificates check $SA = I$. Block certificates check reconstruction. Map certificates check lift support and physical reconstruction. Exact layer uses rational matrices. Numerical layer records tolerance. Numerical canonical-dual, gauge, and map paths require a valid system certificate where their construction depends on the left-inverse law.
- In redundancy $m > n$, C_i need not be idempotent and coefficient blocks $E_\beta \widehat{T} E_\alpha$ are not physical blocks $C_\beta T C_\alpha$.

20.C Failure and edge cases

- Rank-deficient analysis is rejected by `canonical_dual`. A bare numerical system can instead construct with a failed left-inverse certificate. Other failures include incompatible shapes, malformed partition, incompatible composition, confusing raw adjoint with dual adjoint, or treating gauge-equivalent coefficient vectors as equal arrays.
- Portable roundtrip covers supported systems but never reconstructs arbitrary callable family rules.

20.D Example checklist

Chapter 20 presents these four targets. They remain here as reference requirements.

- **E0:** redundant $A : \mathbb{R}^2 \to \mathbb{R}^4$, canonical dual S. Certify $SA = I_2$, analyze/reconstruct x.
- **E1:** choose g with $\|Sg\|$ within the numerical system tolerance. Show $c \sim c+g$, synthesis residual within tolerance, distinct coefficient arrays, and gauge seminorm within tolerance. Use the exact gauge counterpart when claiming literal equality and an exactly zero seminorm.
- **E2:** lift $T : X \to Y$, reconstruct it, partition coefficient blocks, and compare one coefficient block with its physical block.
- **E3:** compose through mismatched middle presentations using transition bridge. Compare raw adjoint and dual adjoint on an oblique frame.

Parts I through IV source and example crosswalk

- Each chapter above expands into symbol cards using the master card schema and keeps the displayed equations as the finite contract spine.
- Existing executable anchors: `typed_grammar.py`, `quickstart.py`, `refinement_pipeline.py`, `exact_lattice_separation.py`, `block15_polyphase_refinement.py`, `general_coordinate_atlas.py`, `classical_coordinate_families.py`, `coordinate_calculus.py`, `formal_affine_coordinate_changes.py`, `recurrence_state_coordinate_atlas.py`, `spectral_packet_coordinates.py`, `euler_to_fibonacci_coordinates.py`, and `block16_analysis_synthesis.py`.
- Example specifications remain planned until implemented and asserted. They must not be represented as shipped scripts. The specification prohibits unlabeled claims and invented executable anchors.

84. Generating functions, arithmetic, sequences, and analytic systems

Specifications for generating functions, arithmetic, sequences, and analytic packets

These specifications supplement the Part V explanations. Every displayed assertion is an implemented definition, a finite certificate contract, or an explicitly labeled numerical, conditional, heuristic, or planned statement.

Part-wide symbolic conventions

Coefficient universes

Let

$$\mathcal{R} \in \{\mathbb{Z},\ \mathbb{Q},\ \mathbb{Z}/M\mathbb{Z},\ \mathbb{F}_p,\ \mathbb{Z}/p^r\mathbb{Z}\}.$$

The exact scalar universes exposed by the Python API are:

$$\texttt{int} \leftrightarrow \mathbb{Z}, \qquad \texttt{Fraction} \leftrightarrow \mathbb{Q}, \qquad \texttt{int in } [0, M-1] \leftrightarrow \mathbb{Z}/M\mathbb{Z}.$$

Booleans are not silently accepted as integers where strict integer validation is part of the contract. Numerical analytic values live in $\mathbb{C}$ with floating residuals and declared tolerances. Several generic containers also accept arbitrary `numbers.Number` values: `HurwitzSeries` without a modulus, `MahlerSeries`, `LinearRecurrence`, `RecurrencePacket`, and `Sequence`. Their algebra is exact for exact `int` or `Fraction` data and numerical for floating or complex data. `Sequence.exact` is declared metadata, not a runtime proof that every returned scalar is exact.

Finite normalized-series universe

For a nonzero weight sequence $\gamma = (\gamma_n)_{n\ge 0}$, $\gamma_0 = 1$, define

$$e_n^{(\gamma)}(z) = \frac{z^n}{\gamma_n}, \qquad \mathcal{R}_{\gamma,N}[z] = \left\{ \sum_{n=0}^{N} a_n e_n^{(\gamma)}(z) : a_n \in \mathcal{R} \right\}.$$

All formal-series operations in this part are finite:

$$\operatorname{trunc}_N : \mathcal{R}[[z]] \longrightarrow \mathcal{R}[z]/(z^{N+1}).$$

No finite prefix is to be described as a proof of an unrestricted infinite identity unless the API supplies a separate exact structural argument.

Truth-status tags for every reference card

- **E**: exact finite computation or exact finite certificate.
- **N**: numerical result with an explicit residual/tolerance contract.
- **C**: conclusion retaining named unchecked assumptions.
- **H**: heuristic, estimator, or bounded-data discovery claim.
- **P**: planned or unimplemented claim.
- **O**: orthogonal optional-backend qualifier. Name the backend without changing the evidence class. Every subsection below has the editorial slots

$$(\text{domain}, \text{map}, \text{hypotheses}, \text{invariant}, \text{certificate}, \text{failure}, \text{example}).$$

Public constants, aliases, and feature keys

The exhaustive ledger must include the singleton exact domains `INTEGER_DOMAIN` and `RATIONAL_DOMAIN`, the default resource object `DEFAULT_GENERATING_BUDGET`, and the compatibility aliases

$$\texttt{NormalizedBasis} = \texttt{NormalizedMonomialBasis} = \texttt{WeightedMonomialBasis}.$$

The package status keys are `arithmetic.FEATURE_KEY = "arithmetic"`, `sequences.FEATURE_KEY = "sequences"`, and `analytic.FEATURE_KEY = "analytic"`. They select feature-status metadata and do not prove a mathematical capability.

Optional-backend ledger

SymPy is required by `guess_linear_recurrence`, `guess_hypergeometric_ratio`, `guess_p_recursive`, `guess_algebraic_gf`, `characteristic_closed_form`, the symbolic-rendering methods on the corresponding guess records, `normalized_cyclotomic_expression`, `verify_cyclotomic_coboundary`, `LinearRecurrence.jump_characteristic_polynomial`, `reciprocal_polynomial`, `appell_polynomial_symbolic`, and `theta_polynomial_symbolic`. SymPy is **not** required by `guess_quasipolynomial`, `rational_gf_from_recurrence`, or `verify_cyclotomic_exponent_relation`.

`reduced_zero_zeta(..., use_computed_zeros=False)` requires `mpmath`. `CyclicSectionFamily.fundamental_matrix` uses SciPy when available and an internal matrix-exponential fallback otherwise. Every function card must repeat its own backend branch rather than applying one package-wide rule.

21. Formal series and weighted bases

21.1 Coefficient-domain protocol

21.1.1 Abstract map signature

Document `CoefficientDomain` (generic form `CoefficientDomain[E]`) as the exact algebraic interface

$$(\mathcal{R}, 0, 1, +, -, \cdot, \mathcal{R}^{\times}, {}^{-1}) \longrightarrow \text{finite normalized-series arithmetic.}$$

Its operations have symbolic signatures

$$\begin{aligned} \text{coerce} &: X \to \mathcal{R}, \\ \text{add}, \text{subtract}, \text{multiply} &: \mathcal{R}^2 \to \mathcal{R}, \\ \text{is_unit} &: \mathcal{R} \to \{\mathrm{T}, \mathrm{F}\}, \\ \text{inverse} &: \mathcal{R}^{\times} \to \mathcal{R}^{\times}, \\ \text{encode} &: \mathcal{R} \to \mathcal{J}, \\ \text{decode} &: \mathcal{J} \to \mathcal{R}. \end{aligned}$$

Here $\mathcal{J}$ is the trusted data-only serialization domain.

21.1.2 Concrete domains and unit hypotheses

Class	Carrier	Unit condition	Inverse failure
`IntegerDomain`	$\mathbb{Z}$	$x = \pm 1$	$\lvert x\rvert \neq 1$
`RationalDomain`	$\mathbb{Q}$	$x \neq 0$	$x = 0$
`ResidueRingDomain`	$\mathbb{Z}/M\mathbb{Z}$	$\gcd(x, M) = 1$	nonunit residue
`PrimeFieldDomain`	$\mathbb{F}_p$	$x \neq 0$	zero residue
`TruncatedPadicDomain`	$\mathbb{Z}/p^r\mathbb{Z}$	$p \nmid x$	positive valuation

`domain_from_descriptor` implements descriptor restoration as the partial map

$$\text{domain_from_descriptor} : \mathcal{J} \rightharpoonup \{\text{known exact domains}\}.$$

Failure branches to exhibit symbolically: malformed descriptors, composite `PrimeFieldDomain` moduli, nonpositive precision, modulus below two, and division by a nonunit.

21.1.3 Symbolic example slot

Over $\mathbb{Z}/8\mathbb{Z}$, compare

$$3^{-1} = 3, \qquad 2 \notin (\mathbb{Z}/8\mathbb{Z})^{\times}.$$

The example must show successful multiplication by the unit inverse and the explicit exception raised for the zero divisor.

21.2 Weighted monomial bases

21.2.1 Basis object and structural constants

Document `BasisDescriptor`, `BasisCertificate`, and `WeightedMonomialBasis` through

$$e_n(z) = z^n/\gamma_n, \qquad C_\gamma(n,k) = \frac{\gamma_n}{\gamma_k \gamma_{n-k}}.$$

The basis maps are

$$\gamma : \mathbb{N} \to \mathbb{Q}^{\times}, \qquad C_\gamma : \{(n,k) : 0 \le k \le n\} \to \mathbb{Q}.$$

Normalized multiplication is

$$\mu_{\gamma,N} : \mathbb{Q}_{\gamma,N}[z]^2 \to \mathbb{Q}_{\gamma,N}[z], \qquad c_n = \sum_{k=0}^{n} C_\gamma(n,k) a_k b_{n-k}.$$

The custom lowering operator is defined by

$$D_\gamma e_n = e_{n-1}, \quad n \ge 1, \qquad D_\gamma e_0 = 0.$$

21.2.2 Basis constructors to expand into individual cards

- `ordinary_basis`: $\gamma_n = 1$.
- `exponential_basis`: $\gamma_n = n!$.
- `factorial_power_basis`(s): $\gamma_n = (n!)^s$.
- `q_factorial_basis`(q): $\gamma_n = [n]_q!$, with `q=1` permitted.
- `fibonacci_factorial_basis`: $\gamma_n = \prod_{j=1}^{n} F_j$.
- `pochhammer_basis`(α): $\gamma_n = (\alpha)_n$.
- `basis_from_values`: finite portable table basis.
- `basis_from_descriptor`: closed descriptor reconstruction. For each constructor, record the admissible parameter set, exact scalar type, whether every γ_n is nonzero through degree N, and whether the basis is portable or only live in memory. Class-member cards must also cover `BasisDescriptor.parameter_map`, `BasisDescriptor.create`, `WeightedMonomialBasis.require_descriptor`, `semantically_equivalent`, `equivalent_through`, `lowering_weight`, `structure_constant`, and `packet_transfer_weight`.

21.2.3 Packet transfer weight

For residue $r \in \{0, \dots, m-1\}$ and packet basis η_q, write

$$P_{m,r} F(z) = z^r G(z^m), \qquad b_q = \frac{\eta_q}{\gamma_{mq+r}} a_{mq+r}.$$

`PacketIdentity` stores exactly `modulus`, `residue`, `source_basis`, `target_basis`, `source_degree`, `packet_degree`, and `valid`. It compares the reconstructed and projected ordinary coefficient vectors. It records basis names, not the normalization tables γ, η, or callable identities.

21.2.4 Certificate and failure ledger

`BasisCertificate` is the finite diagnostics record

$$\left(\begin{array}{c}\texttt{name}, \texttt{degree}, \texttt{nonzero_normalization},\\ \texttt{integral_structure_constants}, \texttt{maximum_denominator},\\ \texttt{maximum_numerator_bits}\end{array}\right).$$

It has no `valid`, `require`, or descriptor-validity field. Descriptor portability is a separate property of `WeightedMonomialBasis`. `WeightedMonomialBasis.finite_certificate` produces this record through the requested finite degree. Failure examples: zero normalization factor, invalid factorial power, unsupported descriptor kind, malformed finite table, and attempted portable restoration of an unrecorded callback.

21.2.5 Symbolic examples

1. Compare the same polynomial in ordinary and exponential coordinates:

$$1 + 2z + 3z^2 = 1\, e_0^{(\exp)} + 2\, e_1^{(\exp)} + 6\, e_2^{(\exp)}.$$

2. Derive the EGF product rule

$$c_n = \sum_{k=0}^{n} \binom{n}{k} a_k b_{n-k}$$

from $C_\gamma(n,k)$ with $\gamma_n = n!$.

21.3 `FormalSeries`: rational normalized calculus

21.3.1 Object signature

Treat

$$\texttt{FormalSeries}(\gamma, (a_0, \dots, a_N)) \in \mathbb{Q}_{\gamma,N}[z].$$

Public operations to receive separate symbolic cards: `degree`, `truncate`, `ordinary_coefficients`, `from_ordinary_coefficients`, `convert`, `add`, `subtract`, `scale`, `multiply`, `hadamard`, `ordinary_derivative`, `ordinary_integral`, `custom_lower`, `reciprocal`, `compose`, `exp`, `log`, `power`, `project`, `packet`, `packet_identity`, and `evaluate`.

21.3.2 Core map signatures

$$\begin{aligned}
\text{convert}_{\gamma\to\eta} &: \mathbb{Q}_{\gamma,N}[z] \to \mathbb{Q}_{\eta,N}[z],\\
\text{multiply} &: \mathbb{Q}_{\gamma,N}[z]^2 \to \mathbb{Q}_{\gamma,N}[z],\\
\text{reciprocal} &: \{F : a_0 \neq 0\} \to \mathbb{Q}_{\gamma,N}[z],\\
\text{compose} &: \{(F,G) : G(0) = 0\} \to \mathbb{Q}_{\gamma,N}[z],\\
\text{project}_{m,r} &: \mathbb{Q}_{\gamma,N}[z] \to \mathbb{Q}_{\gamma,N}[z].
\end{aligned}$$

Basis conversion must preserve the ordinary polynomial:

$$\sum_{n=0}^{N} a_n \frac{z^n}{\gamma_n} = \sum_{n=0}^{N} b_n \frac{z^n}{\eta_n}.$$

Projection is

$$(P_{m,r}F)_n = \mathbf{1}_{n\equiv r \pmod m} a_n.$$

21.3.3 Unit-series branches

The guide must state these preconditions beside the methods:

operation	required constant coefficient
F^{-1}	$F(0) \neq 0$
$\log F$	$F(0) = 1$
$\exp F$	$F(0) = 0$
$F \circ G$	$G(0) = 0$

All equalities are modulo z^{N+1}. `PacketIdentity` records exact finite reconstruction of a projected/interleaved coefficient vector.

21.3.4 Symbolic example

Use

$$F(z) = 1 - z - z^2, \qquad F(z)^{-1} = 1 + z + 2z^2 + 3z^3 + 5z^4 + \cdots \pmod{z^{N+1}}$$

to connect reciprocal series, Fibonacci coefficients, truncation, and exact packet reconstruction.

21.4 `FiniteNormalizedSeries`: domain-aware calculus

21.4.1 Object and operation domain

$$\texttt{FiniteNormalizedSeries}[\mathcal{R}] \in \mathcal{R}_{\gamma,N}[z].$$

Give individual cards for `degree`, `coefficient`, `truncate`, `convert`, `ordinary_coefficients`, `from_ordinary_coefficients`, `add`, `subtract`, `scale`, `multiply`, `reciprocal`, `compose`, `exp`, `log`, `project`, `custom_lower`, and `certificate`.

21.4.2 Transfer certificate

`SeriesTransferCertificate` should be written as the finite proposition

$$\forall n \le N: \quad \operatorname{ordinary}_n(F_\gamma) = \operatorname{ordinary}_n(F_\eta),$$

together with the normalization-factor comparisons used to obtain the target coefficients.

21.4.3 Nonfield failure cases

The guide must explicitly construct a reciprocal that exists over $\mathbb{Q}$ but fails over $\mathbb{Z}$, and a modular reciprocal whose constant term is a zero divisor. No fallback to floating division is permitted. For `exp` and `log`, the constant-term guards are necessary but not sufficient over a general `CoefficientDomain`. Through requested degree N, every embedded integer $1, \dots, N$ that the recurrence divides by must be a unit:

$$f_n = n^{-1} \sum_{k=1}^{n} k g_k f_{n-k}, \qquad (\log F)_n = n^{-1}[z^{n-1}]\, F'/F.$$

Thus degree $N \ge p$ can fail in characteristic p. Basis conversion and ordinary-coordinate access also fail when a required rational normalization factor cannot be coerced into the domain.

21.4.4 Symbolic example

Multiply two factorial-power series over $\mathbb{Q}$, convert the product to ordinary coordinates, convert it back, and require the transfer certificate.

22. Normalized generating functions

22.1 Declarative coefficient sources

22.1.1 `CustomFunctionSpec`

Represent a declarative source as

$$\mathfrak{F} = (\text{name}, \gamma, a : \mathbb{N} \to \mathbb{Q}, \text{source kind}, \text{metadata}).$$

Its finite realization is

$$\text{series}_N(\mathfrak{F}) = \sum_{n=0}^{N} a_n e_n^{(\gamma)}.$$

The reference card must separate the live evaluator from the finite frozen record.

22.1.2 Constructor equations

- `explicit_function`: supplied map $n \mapsto a_n$.
- `linear_recurrence_function`:

$$a_{n+d} = \sum_{j=0}^{d-1} c_j a_{n+j}.$$

- `hypergeometric_function`:

$$a_{n+1} = R(n) a_n.$$

- `rational_function`:

$$F(z) = \frac{P(z)}{Q(z)}, \qquad Q(0) \neq 0.$$

- `algebraic_function`:

$$P(z, F(z)) = 0, \quad P(0, y_0) = 0, \quad P_y(0, y_0) \neq 0.$$

- `euler_product_function`:

$$F(z) = \prod_{m \geq 1} (1 - z^m)^{-c_m}.$$

- `factorial_power_bell_function` and `weighted_factorial_power_bell_function`:

$$\exp\left(x \sum_{m \geq 1} c_m \frac{z^m}{(m!)^s} \right) = \sum_{n \geq 0} P_n(x) \frac{z^n}{(n!)^s}.$$

- `compose_functions`:

$$H(z) = F(G(z)), \qquad G(0) = 0.$$

22.1.3 Registry behavior and failures

`FunctionRegistry.register` always rejects a duplicate stripped/lowercased name with `KeyError`. No replacement option exists. Document `FunctionRegistry.get` as the corresponding normalized-name lookup. The guide must also demonstrate invalid recurrence seeds, a singular rational denominator, non-simple algebraic initial roots, and illegal composition with $G(0) \neq 0$.

22.1.4 Symbolic examples

$$F_{\text{Fib}}(z) = \frac{z}{1 - z - z^2}, \qquad C(z) = 1 + zC(z)^2.$$

Generate the same finite prefixes by declarative recurrence, rational, and algebraic sources, while preserving the different source metadata.

22.2 Eager coefficient families

22.2.1 Exact maps

Each function is a finite map $N \mapsto (a_0, \dots, a_{N-1})$:

- `fibonacci_numbers`, `central_binomial_numbers`, `catalan_numbers`, and `bell_numbers`.
- `partition_numbers`, `apery_numbers`, `signed_euler_numbers`, and `bernoulli_numbers`.
- `generalized_bell_numbers`, `generalized_bell_polynomials`, `weighted_generalized_bell_polynomials`, and `weighted_generalized_bell_numbers`.
- `generalized_bell_hypergeometric_inner` and `finite_differences`.

22.2.2 Identities requiring symbolic derivation

$$A_n = \sum_{k=0}^{n} \binom{n}{k}^2 \binom{n+k}{k}^2,$$

$$B_n^{(s)} = \sum_{m=1}^{n} \binom{n-1}{m-1} \binom{n}{m}^{s-1} B_{n-m}^{(s)},$$

$$P_n(x) = x \sum_{m=1}^{n} c_m \binom{n-1}{m-1} \binom{n}{m}^{s-1} P_{n-m}(x).$$

`finite_differences` should display the full triangular table

$$\Delta^{r+1} a_n = \Delta^r a_{n+1} - \Delta^r a_n.$$

22.2.3 Example and boundary cases

Compare $s = 1$ and $s \geq 2$ generalized Bell coefficients. Reject negative counts and invalid factorial powers. Preserve `Fraction` output for Bernoulli numbers and any rational weighted family.

22.3 Bounded closed-form recognition

22.3.1 Search families

The candidate maps are:

$$a_{n+r} = \sum_{j<r} c_j a_{n+j}, \qquad \frac{a_{n+1}}{a_n} = \frac{P(n)}{Q(n)},$$

$$\sum_{j=0}^{r} P_j(n) a_{n+j} = 0, \qquad P(z, F(z)) = 0,$$

and residue-lane quasipolynomials

$$a_{mq+r} = Q_r(q).$$

22.3.2 Public record/function ledger

Records: `LinearRecurrenceGuess`, `HypergeometricGuess`, `PRecursiveGuess`, `AlgebraicGFGuess`, `QuasiPolynomialGuess`. Search/render functions: `guess_linear_recurrence`, `rational_gf_from_recurrence`, `guess_hypergeometric_ratio`, `guess_p_recursive`, `guess_algebraic_gf`, `guess_quasipolynomial`, `characteristic_closed_form`, plus record methods `equation`, `ratio_expression`, and `expression` where defined.

22.3.3 Scope proposition

Every returned guess has the bounded claim

$$\forall n \in I_{\text{fit}} \cup I_{\text{heldout}} : \quad \mathcal{E}(a, n) = 0.$$

It does **not** imply

$$\forall n \geq 0 : \mathcal{E}(a, n) = 0.$$

The guide must label optional SymPy absence, singular fitting systems, too-short prefixes, zero denominators in a ratio, and no candidate inside the requested degree/order bounds.

22.4 Sections, monoids, adapters, and portable records

22.4.1 Exponential sections

For `custom_exponential`, `custom_section`, and `root_filter_value`, define

$$E_\gamma(z) = \sum_{n \geq 0} \frac{z^n}{\gamma_n}, \qquad P_{m,r} E_\gamma(z) = \sum_{q \geq 0} \frac{z^{mq+r}}{\gamma_{mq+r}},$$

$$P_{m,r} E_\gamma(z) = \frac{1}{m} \sum_{j=0}^{m-1} \omega^{-rj} E_\gamma(\omega^j z).$$

`SectionCycleAudit` and `audit_section_cycle` must separately record the finite lowering cycle and numerical root-filter residual.

22.4.2 Finite monoid convolution

For `FiniteMonoidSeries` (generic form `FiniteMonoidSeries[M]`),

$$(a * b)(n) = \sum_{x \circ y = n} a(x) b(y).$$

Document `additive_series`, `multiplicative_series`, `dirichlet_convolution`, and `prime_valuation_packets`. Addition gives the Cauchy product. Multiplication gives

$$(a * b)(n) = \sum_{d \mid n} a(d) b(n/d).$$

22.4.3 Formal-series/FIR adapter

The convention is

$$\sum_{n=0}^{N} h_n z^n \longleftrightarrow H(z) = \sum_{n=0}^{N} h_n z^{-n}.$$

Document `FIRSeriesAdapter`, `series_to_fir_taps`, `series_to_fir_adapter`, `fir_taps_to_series`, and the numerical method `FIRSeriesAdapter.response`. Its certificate is numerical coefficient/tap agreement, not a proof of filter stability or causality beyond the finite convention.

22.4.4 Portable frozen source

`freeze_custom_function` maps a live source to `FrozenGeneratingFunction`,

$$\texttt{FrozenGeneratingFunction} = (\text{name}, \text{basis snapshot}, (a_0, \dots, a_N), \text{source kind}, \text{closed metadata}).$$

Restoration must execute no callback and import no arbitrary class. Document `degree`, `series`, and `register_generating_codecs`.

22.5 Resource budgets as preconditions

22.5.1 `GeneratingBudget`

Each expansive map is partial:

$$T : B \times X \rightharpoonup Y, \qquad T(B, x) \text{ defined only if } \operatorname{cost}(x) \preceq B.$$

Document `require_degree`, `require_terms`, `require_matrix_dimension`, `require_states`, `require_local_combinations`, `require_modulus`, `require_serialized_bytes`, `require_coefficient_bits`, and the `GeneratingBudget.max_modulus_table` property.

22.5.2 Default-bound table

quantity	default maximum
degree	100,000
coefficient bits	4,000,000
matrix dimension	4,096
reachable states	100,000
local combinations	1,000,000
modulus table	2,000,000
serialized bytes	64 MiB
recursion depth	1,000

Each bound needs one accepted boundary example and one rejected request.

23. Masks, Cartier operators, and digit algebra

23.1 Mahler masks and functional equations

23.1.1 Product and inverse

For radix $b \geq 2$ and unit mask $R(0) = 1$,

$$\mathcal{M}_b[R](z) = \prod_{j \geq 0} R(z^{b^j}), \qquad F(z) = R(z)F(z^b).$$

Document `mahler_mask_product`, `mahler_mask_inverse`, and `certify_mahler_functional_equation` as truncated maps in $\mathbb{Q}[z]/(z^{N+1})$. Failures: $b < 2$, nonunit constant, negative degree, budget excess, and a functional-equation residual that is nonzero in the tested range.

23.1.2 Finite carry compiler

For mask coefficients r_j, carry-state transition weights have the form

$$T_d(q, q') = r_{d+bq'-q}.$$

Document `FiniteMaskCarryPlan`, alias `NormalizedMaskPlan`, `compile_finite_mask_carry_plan`, `DigitCauchyProductPlan`, and `compile_digit_cauchy_product`, including state set, digit order, transitions, evaluation, finite certificate, and `DigitCauchyProductPlan.factor_count`.

23.1.3 Symbolic example

Compile the binary mask $R(z) = 1 + z + z^2$, write all nonzero entries of T_0, T_1, and trace one least-significant-first digit word.

23.2 Carry layers and factorial-power support

23.2.1 Kummer layer polynomial

For $0 \le k \le n$, define

$$L_{n,p}(t) = \sum_{k=0}^{n} t^{v_p\binom{n}{k}}.$$

`KummerLayerDistribution` and `kummer_layer_distribution` store the finite coefficient counts. Also document `zero_borrow_count`, `one_borrow_count`, `factorial_power_support_count`, `factorial_power_support_indices`, `CarryLayerConvolution`, and `factorial_power_convolution_layers`. The record cards must include `KummerLayerDistribution.total` and `KummerLayerDistribution.support_count`.

23.2.2 Survival predicate

For factorial power s modulo p^r,

$$\binom{n}{k}^s \not\equiv 0 \pmod{p^r} \iff s\, v_p\binom{n}{k} < r.$$

The guide must show the strict inequality and test both boundary cases $sv = r-1$ and $sv = r$.

23.3 Frobenius lifts and mask coboundaries

23.3.1 Defect maps

Document `frobenius_defect_mask` and `first_frobenius_lift` through

$$\mathfrak{D}_p R(z) = \frac{R(z^p)}{R(z)^p}, \qquad \mathfrak{L}_p R(z) = \frac{\mathfrak{D}_p R(z) - 1}{p} \pmod{p}.$$

The divisibility by p required by the second expression must be checked, not presumed.

23.3.2 Polynomial coboundary

`polynomial_mask_coboundary`, `PolynomialCoboundaryResult`, and `solve_polynomial_coboundary` concern

$$B(z)Q(z) = A(z)Q(z^b), \qquad Q(0) = 1.$$

Include the convenience property `PolynomialCoboundaryResult.found`. The result must distinguish solved, inconsistent, and underdetermined bounded linear systems. A finite-degree solution is not automatically an infinite analytic factorization.

23.3.3 Analytic and algebraic mask certificates

For `analytic_mahler_product` and `AnalyticMaskApproximation`, require $|z| < 1$ and report a finite product plus conservative tail bound. Both are ordinary floating-complex computations with `Exactness.NUMERICAL`. The bound is conservative but explicitly **not interval-rigorous**. For `certify_rational_mask_algebraic_relation` and `RationalMaskAlgebraicCertificate`, check

$$A(z)F(z)^{p-1} = B(z) \pmod{(p, z^{N+1})}.$$

Document `euler_product_collapse`, `EulerProductCollapse`, and its `collapses` property as finite exponent bookkeeping, with no unrestricted convergence claim.

23.4 Cartier sections and automata

23.4.1 Polynomial maps

Document `polynomial_multiply_mod`, `polynomial_power_mod`, `polynomial_cartier`, `rational_mask_coefficients_mod_prime`, and `cartier_degree_bound` over $\mathbb{F}_p[z]$. The Cartier operator is

$$\Lambda_d\left(\sum_{n\ge 0} a_n z^n\right) = \sum_{n\ge 0} a_{pn+d} z^n, \qquad 0 \le d < p.$$

23.4.2 Automaton compiler

Given

$$B(z)F(z) = A(z)F(z^p) \quad \text{in } \mathbb{F}_p[[z]],$$

document `CartierAutomaton`, `AutomatonCertificate`, `compile_rational_mask_automaton`, and `minimize_cartier_automaton`. Digits are read least-significant first. Evaluation has finite transition cost

$$O(\lfloor \log_p N \rfloor + 1).$$

`AutomatonCertificate` stores only `compared_terms` and the finite-prefix `failures`. Reachable states, transition closure, outputs, and degree bounds belong to `CartierAutomaton`. Document its `number_states` and `theoretical_state_bound` properties separately.

23.4.3 Carry/Cartier equivalence and linear representation

Document `finite_mask_carry_matrices`, `CartierCarryEquivalence`, `certify_cartier_carry_equivalence`, `CartierLinear Representation`, and `compile_cartier_linear_representation`. The finite claim is entrywise equality between the finite-mask carry matrices and Cartier multiplication matrices on the declared state space, not a conjugacy statement about an arbitrary external automaton.

23.4.4 Symbolic example

Evaluate a compiled representation at

$$N = 10^{18} + 12345$$

modulo 5 by displaying its base-five digit word and the corresponding ordered matrix product.

23.5 Lucas-local digit algebra

23.5.1 Local and global kernels

For `DigitKernel`, define

$$K(d,e) = \binom{d}{e}^s \pmod p, \qquad K_{\text{global}}(n,k) = \prod_i K(n_i,k_i).$$

Document `base_digits`, `factorial_power_digit_kernel`, `lift_digit_sequence`, `DigitAlgebraAudit`, and `audit_factorial_power_digit_algebra`. Member cards must cover `DigitKernel.local_weight`, `global_weight`, `local_multiply`, and `global_multiply`. The Lucas theorem used by the audit assumes that p is prime. The current `factorial_power_digit_kernel` runtime guard checks only `p >= 2`. Document that weaker guard separately so a composite input is not presented as a certified Lucas setting.

23.5.2 Exhaustive finite audit

For declared digit depth D, the certificate checks

$$\forall 0 \le n < p^D: \quad (a \star_s b)_n \equiv \prod_i (a \star_s b)_{n_i} \pmod p.$$

It must not be promoted to a universal statement for an arbitrary user kernel. Include one perturbed local weight that the audit rejects.

23.6 Congruence discovery and finite audits

23.6.1 Scalar and profile maps

Inventory `is_prime`, `p_adic_valuation_int`, `p_adic_valuation_fraction`, `rational_mod`, `base_digit_sum`, `mahler_coefficients`, `step_differences`, `DifferenceValuationProfile`, `difference_valuation_profile`, `ResidueLaneFinding`, `scan_residue_lanes`, `minimal_prefix_period`, `berlekamp_massey`, `verify_modular_recurrence`, `DecimationRelation`, and `search_decimation_relation`. Every profile is a finite map from supplied values and search bounds to a record. Infinity may occur only as the valuation of zero.

23.6.2 Audit identities

Place these beside their record classes, with tested ranges printed:

$$C_\gamma(pn+r,pk+i)\equiv C_\gamma(n,k)C_\gamma(r,i)\pmod p,$$

$$a_{pn+r}\equiv\sum_j c_j a_{n+j}\pmod p,$$

$$\begin{bmatrix}ad+b\\ rd+s\end{bmatrix}_q\equiv\binom{a}{r}\begin{bmatrix}b\\ s\end{bmatrix}_q\pmod p,\quad d=\operatorname{ord}_p(q),$$

$$B_{n+p}\equiv B_{n+1}+B_n\pmod p.$$

Record/function families: `LucasBasisAudit`, `audit_generalized_lucas`, `ConvolutionPacketAudit`, `audit_factorial_power_packet_convolution`, `QLucasAudit`, `multiplicative_order_mod`, `audit_q_lucas`, `DigitSumCongruenceAudit`, `audit_generalized_bell_digit_sum`, `WeightedDigitSumCongruenceAudit`, `audit_weighted_generalized_bell_digit_sum`, `RelationAudit`, `audit_touchard`, `audit_apery_supercongruence`, and `audit_partition_lane`. Each card needs `tested_cases`, `failure_count`, first counterexample where available, and a false-relation control.

24. Prime-power, Bell, cyclotomic, and q-Kummer systems

24.1 Exact prime-power binomial compiler

24.1.1 Valuation/unit decomposition

For prime p, precision $r\ge 1$, and $0\le k\le n$,

$$\binom{n}{k}=p^v u,\qquad p\nmid u,\qquad v=v_p\binom{n}{k}.$$

Document `factorial_valuation`, `integer_valuation`, `binomial_valuation`, `borrow_count`, `PrimePowerBinomial`, and `PrimePowerUnitCompiler`. The compiler card must include `PrimePowerUnitCompiler.unit_factorial` and `PrimePowerUnitCompiler.binomial_data`. The compiled result stores the exact valuation, unit part, and residue modulo p^r. The survival predicate is

$$\texttt{survives}\iff v<r.$$

24.1.2 Normalized prime-power kernel

For

$$\gamma_n=c^n(n!)^s u_n,$$

document `NormalizedKernelResidue`, `constant_unit_sequence`, and `PrimePowerKernelCompiler` through

$$C_\gamma(n,k)=\frac{\gamma_n}{\gamma_k\gamma_{n-k}}pmodp^r.$$

The compiler must separate the carry valuation from the unit ratio. Strict guards: prime modulus base, positive precision, nonnegative indices, $k\le n$, and unit-valued twist data.

24.1.3 Cost and example

Prefix storage is $O(p^r)$. A memoized query uses $O(\log_p n)$ scale steps. Check

$$\binom{137}{52}^2 \pmod{3^5}$$

against direct exact arithmetic and include the valuation-boundary branch.

24.2 Carry-linear normalization

24.2.1 Classification target

Document `CarryLinearValuation`, `CarryLinearCertificate`, and `classify_carry_linear_valuation` for a supplied valuation callback ν:

$$\nu(n) = an + s\, v_p(n!).$$

Include `CarryLinearValuation.defect`, the pointwise difference between the observed valuation and this affine/factorial model. Then

$$\nu(n) - \nu(k) - \nu(n-k) = s\, v_p\binom{n}{k}.$$

This is a finite classification certificate over the declared prefix, not a proof for an arbitrary callback outside that prefix.

24.2.2 Unit twists

Document `base_digits`, `digit_unit`, `local_normalized_kernel`, and `digit_factorized_normalized_kernel` with

$$u(n) = \prod_i w_{n_i} \pmod{p}.$$

Failure cases: wrong weight-table length, zero/nonunit digit weight where a unit is required, composite p, and index/radix violations.

24.3 Bell digit reductions

24.3.1 Pointed subindex identity

Document `bell_period_bound`, `pointed_subindex_polynomial`, `PointedSubindexCertificate`, and `certify_pointed_subindex_identity` through the finite congruence

$$P_{n,p}(u) \equiv (1+u)^{s_p(n)-1} \pmod{p}.$$

The exact meaning and treatment of the $s_p(n) = 0$ endpoint must follow the implementation rather than an informal negative exponent.

24.3.2 Generalized Bell reduction

Under $s \geq 2$ and $p-1 \mid s-1$,

$$B_n^{(s)}(x) \equiv B_{s_p(n)}^{(1)}(x) \pmod{p}, \qquad s \geq 2, \qquad p-1 \mid s-1.$$

Here $B_j^{(1)}(x)$ is the ordinary Bell polynomial. The implementation constructs the reduced family with power 1. It does not reuse power s on the right-hand side. Document `BellDigitReduction`, `generalized_bell_digit_reduction`, `weighted_bell_digit_reduction`, `generalized_bell_parity`, `BellParityAutomaton`, and `BellResidueAutomaton`. The finite period bound is

$$1 + p + \cdots + p^{p-1} = \frac{p^p - 1}{p-1}.$$

24.3.3 Symbolic example

Use $(n, p, s) = (137, 5, 9)$. Display the base-five digits, digit sum, reduced index, direct residue, compiled residue, and certificate fields.

24.4 q-Kummer valuation branches

24.4.1 Exact Gaussian objects

Document `multiplicative_order_mod_prime`, `q_integer`, `q_factorial`, and `gaussian_binomial`:

$$[n]_q = \frac{q^n - 1}{q - 1}, \quad [n]_q! = \prod_{j=1}^{n} [j]_q, \quad \begin{bmatrix} n \\ k \end{bmatrix}_q = \frac{[n]_q!}{[k]_q![n-k]_q!}.$$

24.4.2 Decomposition map

`q_binomial_valuation_decomposition` has the partial map signature

$$(n, k, q, p) \longmapsto (\text{block length}, \text{quotient carries}, \text{residue carry}, \text{endpoint term}, v_p\left(\begin{bmatrix} n \\ k \end{bmatrix}_q\right)).$$

Document all branches exactly: 1. $p \mid q$: the Gaussian binomial is a p-adic unit. 2. Odd $p \nmid q$: $d = \operatorname{ord}_p(q)$. 3. $p = 2$, odd q: block length 2 and lift constant $v_2(q + 1)$. Also document `QKummerDecomposition`, `q_binomial_valuation_direct`, and `q_binomial_support`, with

$$\begin{bmatrix} n \\ k \end{bmatrix}_q^s \not\equiv 0 \pmod{p^r} \iff s\, v_p\left(\begin{bmatrix} n \\ k \end{bmatrix}_q\right) < r.$$

24.4.3 Adversarial examples

- Main example: $(n, k, q, p) = (48, 22, 2, 5)$.
- Endpoint checks: $k = 0$, $k = n$, and $k > n$.
- Branch checks: $p \mid q$, odd-prime unit base, and dyadic odd base.
- Record method-specific invalid-index behavior: `q_binomial_valuation_decomposition` rejects $k < 0$ or $k > n$, while `gaussian_binomial` returns zero for those subindices. `q_integer` and `q_factorial` reject negative indices. `q_binomial_support` currently returns an empty tuple for a negative total index rather than raising.
- The integer q-Kummer maps that evaluate q-integers require $q > 1$, unlike `q_factorial_basis`, which permits `q=1`. Reject nonprime p and nonpositive power or precision on the branches that accept those parameters.

24.5 Cyclotomic collapse

24.5.1 Orbit decomposition

Write every index as

$$m = up^j, \qquad p \nmid u.$$

Document `p_free_orbit`, `CyclotomicCollapse`, `cyclotomic_coboundary`, `normalized_cyclotomic_expression`, `verify_cyclotomic_coboundary`, and `verify_cyclotomic_exponent_relation`. Include the boolean property `CyclotomicCollapse.collapses`.

24.5.2 Exact obstruction

For normalized cyclotomic exponents, solve

$$R(z) = \frac{Q(z)}{Q(z^p)}.$$

Writing the exponent at up^j as $e_{u,j}$, the implementation reports a coboundary obstruction exactly when

$$e_{u,0} \neq 0$$

for a p-free orbit. This differs from `euler_product_collapse`, whose obstruction is a nonzero terminal orbit sum. Optional SymPy verifies the symbolic expression. The divisor-lattice verifier remains exact without SymPy.

24.5.3 Positive and negative examples

Show one exponent ledger that telescopes along every orbit and one with a single uncancelled orbit residual. Print both the candidate Q and the obstruction map.

25. Local arithmetic models

25.1 Exact local domains and valuations

25.1.1 Ring maps

Document `ModularRing`, `PrimeField`, and `TruncatedPadic` as

$$\mathbb{Z} \to \mathbb{Z}/M\mathbb{Z}, \quad \mathbb{Z} \to \mathbb{F}_p, \quad \mathbb{Z} \to \mathbb{Z}/p^r\mathbb{Z}.$$

Include all public operations: `normalize`, `add`, `subtract`, `multiply`, `power`, `is_unit`, `inverse`, `prime`, `modulus`, `ring`, `valuation`, `refine`, and `coarsen`. Refinement changes the visible modulus, not the mathematical knowledge encoded by an existing coarse residue. Coarsening is canonical reduction.

25.1.2 Valuation identities

Inventory `digit_sum`, `padic_valuation`, `factorial_valuation`, `binomial_valuation`, `binomial_valuation_from_digits`, `falling_factorial`, `carmichael_exponent_prime_power`, `unit_difference_value`, `unit_difference_valuation`, `verify_binomial_digit_formula`, and `exact_binomial`.

$$v_p(n!) = \sum_{j \geq 1} \left\lfloor \frac{n}{p^j} \right\rfloor,$$

$$v_p\binom{n}{k} = \frac{s_p(k) + s_p(n-k) - s_p(n)}{p-1}.$$

Use $v_p(0) = +\infty$. Reject nonprime p, negative factorial indices, and invalid binomial subindices according to each function's source contract.

25.2 Hurwitz-series algebra

25.2.1 Product and inverse

For

$$A(z) = \sum_{n=0}^{N} a_n \frac{z^n}{n!}, \qquad B(z) = \sum_{n=0}^{N} b_n \frac{z^n}{n!},$$

document `hurwitz_product` and `hurwitz_inverse` through

$$(A \star_H B)_n = \sum_{k=0}^{n} \binom{n}{k} a_k b_{n-k}, \qquad (A \star_H A^{-1})_n = \delta_{n0}.$$

`HurwitzSeries` cards: `degree`, `coefficient`, `truncate`, `multiply`, `inverse`, `evaluate_egf`, `identity`, and `exponential_mode`. Without a modulus, coefficients may be arbitrary `Number` values: `int` and `Fraction` inputs give exact finite algebra, whereas floating or complex inputs give numerical algebra. Modular mode retains exact residue arithmetic.

25.2.2 Subgroup selector and compressed inverse

For odd prime p and $m \mid p-1$,

$$\frac{1}{m} \sum_{\omega \in \mu_m} \omega^n = \mathbf{1}_{m \mid n} \quad \text{in } \mathbb{F}_p.$$

Document `subgroup_roots`, `subgroup_selector`, `compressed_hurwitz_inverse`, and `compressed_period`, including

$$u_0 = 1, \qquad u_n = -\sum_{q<n} \binom{mn}{mq} u_q \pmod{p}, \qquad h = \frac{p-1}{m}.$$

The positive-tail period statement must not be rewritten as a period including the exceptional constant term without verification.

25.3 Standard residual windows

Document `PeriodicGeneratingFunction`, `StandardWindow`, `standard_window_inverse`, `standard_window_period`, and `subgroup_standard_window_inverse`. The residual OGF has the form

$$u_0 + \frac{P(z)}{1 - z^h}, \qquad h = (p-1)/m.$$

The uniform positive-tail period and residual OGF require

$$p \text{ odd prime}, \qquad m \mid p-1, \qquad h = (p-1)/m.$$

`StandardWindow(2,1)` can be constructed, but its `period` and `rational_generating_function` reject this exceptional prime. The periodic claim starts at coefficient 1. The constant term is exceptional. `StandardWindow.certificate` must check address independence, recurrence, claimed positive-tail period, and minimum observed period. Add member cards for `has_uniform_period`, `reduced_inverse`, `exact_coefficients`, `residues`, `rational_generating_function`, and `minimum_period`. The worked example uses $p = 7, m = 2$ and address 3.

25.4 Odd and dyadic Euler coordinates

25.4.1 Source sequences and kernels

Inventory `bernoulli_numbers`, `signed_euler_numbers`, `signed_euler_number`, `euler_zigzag_numbers`, `euler_zigzag_number`, `odd_power_sum`, `dyadic_source`, `dyadic_beta`, `dyadic_kernel`, `odd_kernel`, `EulerTruncation`, `EulerLocalCoordinates`, `dyadic_kernel_valuation`, and `dyadic_row_weight`.

$$\operatorname{sech} t = \sum_{n \geq 0} E_n \frac{t^n}{n!}, \qquad \sec t + \tan t = \sum_{n \geq 0} A_n \frac{t^n}{n!}.$$

For even n,

$$E_n = \sum_{r=0}^{n/2} \binom{n}{2r} \kappa_{p,r} A_{p,n-2r}.$$

25.4.2 Dyadic and odd branches

$$A_{2,n} = \frac{3^{n+2} - 1}{4(n+1)(n+2)},$$

$$\kappa_{2,0} = 1, \qquad \kappa_{2,r} = -2^{4r}(2r-1)B_{2r} \quad (r > 0),$$

$$\kappa_{p,r} = (-1)^r A_{2r+1} p^{2r} \quad (p \text{ odd}).$$

For $r > 0$,

$$v_2(\kappa_{2,r}) = 4r - 1.$$

Truncation at depth d uses the exact moduli 2^{4d+3} and p^{2d+2} in their respective branches.

25.4.3 Certificate anatomy

`EulerTruncation` stores truncated value, exact Euler value, error, modulus, and congruence status. `EulerLocalCoordinates.certificate` checks forward and inverse reconstruction and the finite row-valuation ledger. The example must print every retained row and the first discarded row. The `EulerLocalCoordinates` ledger must also name `is_dyadic`, `inverse_kernel`, `reconstruct`, `inverse_reconstruct_source`, `kernel_valuation`, `row_weight`, `formula_row_weight`, and `sharp_modulus`.

25.5 Mahler transfer and arithmetic polyphase

25.5.1 Newton/Mahler coordinates

Document `generalized_binomial`, `difference_table`, `mahler_coefficients`, and `MahlerSeries`:

$$f(x) = \sum_{r=0}^{d} \Delta^r f(0) \binom{x}{r}.$$

Cards: `degree`, `from_values`, `evaluate`, `first`, `difference`, `affine_subsequence`, `valuation_ledger`, and `reconstruction_certificate`. `MahlerSeries` accepts general numeric values. Its finite identities and certificate are exact for exact data and numerical for floating or complex data. The reconstruction certificate selects that status from the value types.

25.5.2 Affine kernel

For

$$\binom{mq+s}{r} = \sum_{k} K_{m,s}(r,k) \binom{q}{k},$$

$$K_{m,s}(r,k) = \sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} \binom{mj+s}{r}.$$

Document `affine_mahler_kernel`, `affine_kernel_matrix`, `affine_kernel_composition_certificate`, `prime_power_kernel_residue`, and `prime_power_kernel_certificate`, including

$$K_{m,s} K_{n,t} = K_{mn,mt+s},$$

$$K_{p^a,s}(r,k) \equiv \binom{s}{r-p^a k} \pmod{p}.$$

25.5.3 Unit and matrix modes

Document `UnitModeMahler`, `matrix_mahler_coefficients`, and `evaluate_matrix_mahler` through

$$u^{hx+j} = u^j \sum_{r \geq 0} (u^h - 1)^r \binom{x}{r},$$

with $u^h - 1$ replaced by $C^h - I$ for matrix modes. Include `UnitModeMahler.increment` and `UnitModeMahler.valuation_slope`.

25.5.4 Polyphase maps

Document `ArithmeticPolyphase`, `polyphase_analyze`, `polyphase_synthesize`, `mixed_radix_address`, `mixed_radix_digits`, and `mahler_polyphase`:

$$a \mapsto ((a_{mq+r})_{q \geq 0})_{r=0}^{m-1}.$$

Include `ArithmeticPolyphase.reconstruct` as the class-level synthesis map. Nested digits are least-significant first:

$$j = d_0 + r_0 d_1 + r_0 r_1 d_2 + \cdots.$$

Examples must verify analysis/synthesis identity, nested/direct address agreement, and refine/coarsen equality.

25.6 Recurrence packets

25.6.1 Exact state evolution

Document `matrix_power_exact`, `matrix_power_mod`, `determinant_integer`, `OrbitPeriod`, `LinearRecurrence`, `RecurrencePacket`, `second_order_trace`, `second_order_jump`, `fibonacci_recurrence`, and `lucas_recurrence`.

$$x_{n+d} = \sum_{i=0}^{d-1} c_i x_{n+i}, \qquad X_{n+1} = CX_n.$$

The residue packet obeys

$$X_{mk+r} = (C^m)^k X_r.$$

`LinearRecurrence` and `RecurrencePacket` accept general numeric coefficients and initial values. Their evolution is exact for exact data and numerical for floating or complex data. Their certificates select `EXACT` versus `NUMERICAL` from those types.

25.6.2 Public-member cards

For `LinearRecurrence`: `order`, `companion_matrix`, `initial_state`, `term`, `term_mod`, `first`, `state`, `jump_matrix`, `residue_packet`, `period_mod`, `characteristic_polynomial`, `jump_characteristic_polynomial`, and `certificate`. For `RecurrencePacket`: `jump_matrix`, `initial_state`, `state`, `term`, `term_mod`, `first`, and `certificate`.

25.6.3 Finite-state and symbolic boundaries

Period classification modulo M is exact in a finite state space. If the companion matrix is invertible modulo M, preperiod must be zero. Symbolic characteristic-polynomial rendering requires optional SymPy. Example: compute $F_{1{,}000{,}000}$ mod $1{,}000{,}003$ without constructing the full integer, then classify the Fibonacci orbit modulo 32.

25.7 Carmichael jumps and simultaneous congruences

Document `DifferenceCongruence`, `local_unit_jump`, `unit_mode_for_precision`, `finite_difference_value`, `certify_difference_congruence`, and `simultaneous_unit_difference`.

$$\Delta_h^r f(n) = \sum_{k=0}^{r} (-1)^{r-k} \binom{r}{k} f(n + kh).$$

For a local unit u, $h = \lambda(p^d)$ gives

$$v_p(\Delta_h^r u^n) \geq dr.$$

For primes p_i, use

$$h = \operatorname{lcm}_i \lambda(p_i^{d_i}).$$

The example should certify the 2-, 3-, and 5-adic lower bounds and include a nonunit-base rejection.

26. Exact sequence execution

26.1 Lazy sequence protocol

26.1.1 `Sequence`

Model

$$a : \mathbb{N} \to \mathcal{R}$$

with cached numeric evaluation carrying an explicit exactness flag. `Sequence.exact` is constructor metadata rather than an enforced proof of scalar arithmetic. Document `term`, `first`, `residue`, `modulo`, `map`, finite slicing, and lazy iteration.

$$\text{residue}_{m,r}(a)(k) = a_{mk+r}, \qquad \text{modulo}_M(a)(k) = a_k \bmod M.$$

Transforms propagate the exactness flag by default. `map(..., exact=...)` may override it explicitly. `modulo` requires integral rational terms. Slices require a finite stop. Infinite iteration is intentionally unbounded.

26.2 Exact catalog

26.2.1 Constructors

Document `fibonacci_sequence`, `lucas_sequence`, `signed_euler_sequence`, `euler_zigzag_sequence`, `bernoulli_sequence`, `catalan_sequence`, `bell_sequence`, `motzkin_sequence`, `partition_sequence`, `apery_sequence`, `thue_morse_sequence`, `sequence_catalog`, and `get_sequence`.

26.2.2 Defining equations

$$F_{n+2} = F_{n+1} + F_n, \quad (F_0, F_1) = (0, 1),$$
$$L_{n+2} = L_{n+1} + L_n, \quad (L_0, L_1) = (2, 1),$$
$$C_n = \frac{1}{n+1}\binom{2n}{n}, \qquad B_{n+1} = \sum_{k=0}^{n} \binom{n}{k} B_k,$$
$$n\,p(n) = \sum_{k=1}^{n} \sigma(k) p(n-k),$$
$$t_{2n} = t_n, \qquad t_{2n+1} = 1 - t_n.$$

Print aliases `apery-zeta3`, `euler-zigzag`, `signed-euler`, `thue-morse`, and `thuemorse`. Unknown names must fail explicitly.

26.3 Automatic sequences

26.3.1 DFAO model

Document `base_digits`, `AutomaticSequence`, and `thue_morse_automaton`. For base b, states Q, transition δ, initial state q_0, and output τ,

$$a_n = \tau(\delta^*(q_0, \text{digits}_b(n))).$$

Digits are most-significant first in this namespace. The initial state must have a zero loop so canonical leading zeros do not change the value.

26.3.2 Cards and certificate

Document `state_count`, `state`, `term`, `first`, `residue_model`, `to_sequence`, and `certificate`. For $0 \le r < b^e$,

$$\text{residue_model}(e, r)(n) = a_{b^e n + r}.$$

The example must display the two-state Thue-Morse transition graph, certify the first 1,000 terms, and compile all residue models below 2^5.

26.4 Holonomic recurrences

26.4.1 Model

Document type alias `Polynomial`, `evaluate_polynomial`, `HolonomicRecurrence`, `motzkin_recurrence`, and `apery_recurrence`:

$$\sum_{j=0}^{r} P_j(n) a_{n+j} = 0.$$

The final coefficient $P_r(n)$ must be nonzero at every executed index. Terms and polynomial coefficients are exact rationals.

26.4.2 Apéry recurrence

$$(n+1)^3 A_n - \left(34(n+1)^3 + 51(n+1)^2 + 27(n+1) + 5\right) A_{n+1} + (n+2)^3 A_{n+2} = 0,$$
$$(A_0, A_1) = (1, 5).$$

The finished guide must print the Motzkin coefficient tuples directly from the source and derive its first terms, avoiding hand-copied polynomial errors.

26.4.3 Certificate/failure split

Document `order`, `coefficient`, `term`, `first`, `to_sequence`, and `certificate`. Fail on insufficient initial values, zero leading coefficient at an executed index, invalid index, or malformed polynomial coefficients.

26.5 Sequence compiler and strongest-model selection

26.5.1 Selection order

`compile_sequence` follows this symbolic decision relation:

$$\begin{aligned}\text{declared constant recurrence} \succ \text{declared DFAO} \succ \text{declared holonomic model}\\ \succ \text{prefix-fitted recurrence} \succ \text{direct evaluator}.\end{aligned}$$

Document `detect_linear_recurrence`, `recurrence_generating_function`, `CompiledSequence`, and `compile_sequence`.

26.5.2 Recurrence OGF

For

$$a_{n+d} = \sum_{j=0}^{d-1} c_j a_{n+j},$$

$$Q(z) = 1 - c_{d-1} z - c_{d-2} z^2 - \cdots - c_0 z^d, \qquad F(z) = \frac{P(z)}{Q(z)}.$$

Cards for `CompiledSequence`: `term`, `first`, `modulo`, and `generating_function`.

26.5.3 Truth-status boundary

A detected relation gives

$$\forall n \in I_{\text{sample}} : \mathcal{R}(a, n) = 0,$$

not an unconditional infinite recurrence. The compiled record must retain the strategy and certificate provenance.

26.6 Exact transforms

Document `binomial_transform_values`, `binomial_transform`, `inverse_binomial_transform_values`, `inverse_binomial_transform`, `finite_difference`, `partial_sums`, and `cauchy_product`:

$$b_n = \sum_{k=0}^{n} \binom{n}{k} a_k, \qquad a_n = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} b_k,$$

$$\Delta_h^r a_n = \sum_{k=0}^{r} (-1)^{r-k} \binom{r}{k} a_{n+kh},$$

$$s_n = \sum_{k=0}^{n} a_k, \qquad c_n = \sum_{k=0}^{n} a_k b_{n-k}.$$

Examples: exact transform/inverse identity. Fifth difference of a quartic is zero. Cauchy coefficients equal ordinary-GF multiplication coefficients.

27. Cyclic analytic systems

27.1 Exact/numerical boundary

The chapter opens with the type split

$$\text{finite coefficient algebra over } \mathbb{Q} \quad \oplus \quad \text{numerical entire-function evaluation over } \mathbb{C}.$$

`analytic.status()` and `analytic.require()` report feature availability only. They do not certify a user-supplied analytic claim.

27.2 Cyclic packets and projections

27.2.1 Coefficient projector

Document `cyclic_project_coefficients`, `cyclic_packets`, `cyclic_reconstruct`, `cyclic_project_value`, `cyclic_product_packets`, and `cyclic_projection_certificate`.

$$(P_{m,r}a)_n = \mathbf{1}_{n \equiv r \pmod m} a_n,$$

$$P_{m,r} f(z) = \frac{1}{m} \sum_{\ell=0}^{m-1} \omega^{-r\ell} f(\omega^\ell z), \qquad \omega = e^{2\pi i/m}.$$

Packet multiplication is cyclic convolution in the residue address:

$$(AB)_t = \sum_{r+s \equiv t \pmod m} A_r B_s.$$

The finite coefficient reconstruction is exact. The floating norm in its certificate is a diagnostic encoding of that reconstruction residual.

27.3 Transfer and signed section families

27.3.1 Entire sections

Document `transfer_section`, `signed_section`, `transfer_sections`, `signed_sections`, `denominator`, `denominator_root_sum`, `denominator_derivative`, `transfer_shift_matrix`, `signed_shift_matrix`, `cyclic_addition`, `section_certificate`, and `CyclicSectionFamily`.

$$T_{m,r}(z;c)=\sum_{n\ge 0}\frac{(cz)^{mn+r}}{(mn+r)!},$$

$$S_{m,r}(z)=\sum_{n\ge 0}\frac{(-1)^n z^{mn+r}}{(mn+r)!},\qquad D_m(z)=S_{m,0}(z).$$

27.3.2 Root sum and finite dynamics

For

$$\eta_k=e^{(2k+1)\pi i/m},$$

$$D_m(z)=\frac{1}{m}\sum_{k=0}^{m-1}e^{\eta_k z},\qquad D_m^{(r)}(z)=\frac{1}{m}\sum_k \eta_k^r e^{\eta_k z}.$$

The shift matrices satisfy

$$J_T(c)^m=c^m I,\qquad J_S^m=-I.$$

Only the unit-scale transfer matrix has $J_T(1)^m=I$. The signed constructor is unscaled. The generator used by a signed `CyclicSectionFamily` with scale c is cJ_S, so

$$(cJ_S)^m=-c^m I.$$

`cyclic_addition` is finite coordinate convolution for adding arguments. `section_certificate` is numerical agreement between series and root-sum representations, with truncation/tolerance stated.

27.3.3 Class cards

For `CyclicSectionFamily`, document `evaluate`, `vector`, and `fundamental_matrix`, including order, residue, scale, derivative index, dtype, and error conditions.

27.4 Reciprocal and Appell families

27.4.1 Reciprocal powers

Document `logarithmic_coefficients`, `reciprocal_coefficients`, `reciprocal_polynomial`, `reciprocal_value`, `transfer_tangent`, `transfer_tangent_coefficients`, and `reciprocal_semigroup_certificate`.

$$D_m(z)^{-r}=\sum_{n\ge 0}P_{m,n}(r)\frac{z^{mn}}{(mn)!},$$

$$-\frac{D_m'(z)}{D_m(z)}$$

is the transfer tangent. Parameter addition gives the exact finite identity

$$P_{m,n}(r+s)=\sum_{q=0}^{n}\binom{mn}{mq}P_{m,q}(r)P_{m,n-q}(s).$$

Rational parameters remain exact. Complex parameters are numerical. `reciprocal_value` uses the principal complex branch and rejects $D_m(z)=0$. Symbolic polynomial construction is optional-SymPy.

27.4.2 Congruential Appell families

Document `congruential_reciprocal_coefficients`, `congruential_inverse`, `appell_polynomial`, `appell_coefficients`, `appell_polynomial_symbolic`, `theta_polynomial`, and `theta_polynomial_symbolic`.

$$\Phi_{m,j}(w) = j! \sum_{k\ge 0} \frac{w^k}{(mk+j)!},$$

with reciprocal coefficients from $\Phi_{m,j}(w)^{-r}$. Then

$$A_n^{(m,j,r)}(x) = \sum_{k=0}^{\lfloor n/m \rfloor} \binom{n}{mk} C_k^{(m,j,r)} x^{n-mk}.$$

The theta polynomial is $(mn)!$ times the coefficient of w^n in

$$\left(\sum_{k\ge 0} \frac{u^{mk} w^k}{(mk)!} \right)^{-1} \left(\sum_{k\ge 0} \frac{w^k}{(mk)!} \right)^{-u}.$$

The guide should connect `congruential_inverse` to the standard-window chapter without conflating rational exact coefficients with modular residual windows.

27.5 Internal finite-series helpers

Document these as advanced module API rather than recommended top-level imports: `validate_order`, `validate_degree`, `multiply_series`, `inverse_series`, `logarithmic_coefficients`, `power_series_from_log`, `signed_denominator_coefficients`, and `positive_section_coefficients`. Their finite identities include

$$-\log A(w) = \sum_{n\ge 1} \kappa_n \frac{w^n}{n},$$

$$\exp\left(r \sum_{n\ge 1} \kappa_n \frac{w^n}{n} \right),$$

$$D_m(w) = \sum_{n\ge 0} \frac{(-1)^n w^n}{(mn)!}, \qquad \Phi_{m,j}(w) = j! \sum_{n\ge 0} \frac{w^n}{(mn+j)!}.$$

All are exact through finite degree for `Fraction` inputs. The guide must avoid presenting an internal helper as a stronger public stability promise.

27.6 Positive zero strings and finite zero diagnostics

27.6.1 Public maps

Document these public maps and records:

- `ZeroStringResult`, `asymptotic_positive_zero`, and `positive_zero_string`.
- `zero_count_asymptotic`, `hadamard_partial_product`, and `reciprocal_coefficient_from_zeros`.
- `reduced_zero_zeta` and `CyclicDenominator`.

Class cards cover `ZeroStringResult.rotational_orbits` and `CyclicDenominator.derivative`, `positive_zeros`, `zero_count`, and callable evaluation.

27.6.2 Numerical models

The positive asymptotic seed is

$$\rho_k^{(0)} = \frac{\pi(k+\frac{1}{2})}{\sin(\pi/m)}.$$

Leading count models are

$$N_m(R) \sim \frac{m\sin(\pi/m)}{\pi}R, \qquad N_m^{\mathrm{red}}(R) \sim \frac{\sin(\pi/m)}{\pi}R^{1/m}.$$

The finite products and sums are

$$H_K(z) = \prod_{k=0}^{K-1}\left(1-\frac{z^m}{\rho_k^m}\right), \qquad Z_K(s) = \sum_{k=0}^{K-1}\rho_k^{-ms}.$$

27.6.3 Mandatory scope box

`positive_zero_string` certifies only the returned numerical roots:

$$\widetilde{D}_m(x) = e^{-x\cos(\pi/m)}D_m(x) = \frac{1}{m}\sum_{j=0}^{m-1} e^{(\eta_j-\cos(\pi/m))x},$$

$$|\widetilde{D}_m(\rho_k)| \le 20\tau, \qquad 0<\rho_0<\rho_1<\cdots<\rho_{K-1},$$

where τ is the requested tolerance. `ZeroStringResult.residuals` stores this scaled residual, not $|D_m(\rho_k)|$. It does not certify global exhaustion. `reduced_zero_zeta` omits an unchecked tail. Its Hurwitz-zeta leading model has an unchecked correction and is conditional. `reciprocal_coefficient_from_zeros` is a finite approximation, not an exact infinite-product coefficient identity.

27.6.4 Symbolic/numerical example

For $m = 4$: 1. form the exact finite secant reciprocal coefficients $(1, 1, 5, 61, ...)$. 2. Compute four positive zero representatives numerically. 3. Print each Newton residual and ordering gap. 4. Compare a finite Hadamard coefficient with the exact reciprocal coefficient. 5. Label the discrepancy as truncation error, not theorem failure.

Cross-chapter dependency and example matrix

Formal dependencies

$$\begin{gathered}\text{domains} \to \text{weighted bases} \to \text{finite series} \to \text{declarative functions} \\ \to \text{mask/Cartier compilers} \to \text{prime-power systems.}\end{gathered}$$

$$\begin{gathered}\text{local arithmetic} \to \text{recurrence packets} \to \text{lazy sequences} \\ \to \text{compiled execution.}\end{gathered}$$

$$\begin{gathered}\text{cyclic projections} \to \text{entire sections} \to \text{reciprocal/Appell families} \\ \to \text{finite zero diagnostics.}\end{gathered}$$

Existing runnable example anchors

- `custom_generating_functions.py`: normalized series, rational/algebraic sources, basis conversion, frozen records.
- `mahler_cartier_compilers.py`: masks, carry plans, Cartier automata, coboundaries, large-index evaluation.
- `prime_power_generating.py`: prime-power binomials, Bell digit reduction, q-Kummer decomposition.
- `standard_window_mahler.py`: standard windows and affine Mahler transfer.
- `local_euler_coordinates.py`: odd/dyadic Euler branches and truncation certificates.
- `recurrence_packets.py`: exact/modular recurrence execution and periods.
- `sequence_compiler.py`: declared, detected, and fallback sequence models.
- `cyclic_analytic.py`: cyclic sections, reciprocal/Appell coefficients, numerical zero records.

Adversarial example requirements

1. Reciprocal over a nonfield with a nonunit constant coefficient.
2. Composition with nonzero inner constant.
3. False finite-prefix recurrence that passes fit data but fails held-out data.
4. Perturbed Lucas-local digit kernel rejected by exhaustive finite audit.
5. Prime-power support case at the exact valuation cutoff.
6. q-Kummer input routed through each valuation branch.
7. Cyclotomic exponent ledger with one surviving orbit obstruction.
8. Analytic zero list with an intentionally insufficient Newton tolerance.

Per-card completion invariant

No symbol card in Chapters 21 through 27 is complete until it contains

$$\boxed{\begin{gathered}\text{import path} + \text{Python signature} + \text{mathematical map} \\ +\text{domain} + \text{hypotheses} + \text{truth status} \\ +\text{certificate fields} + \text{failure branches} + \text{example}\end{gathered}}.$$

The reader explanations and these specifications must agree without weakening or broadening any recorded claim.

85. Algorithms and signals

Specifications for structured algorithms and finite signals

These specifications supplement Chapters 28 through 36A. Each item records a definition, API contract, derivation, example requirement, certificate interpretation, or failure boundary.

VI.0 Common symbols, claim labels, and result types

VI.0.1 Scalar and array domains

- Scalar field: $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, with selected routines also accepting exact object scalars.
- Dense vector: $x \in \mathbb{K}^n$.
- Batched right-hand side: $X \in \mathbb{K}^{n \times r}$, $r \geq 1$.
- Matrix: $A \in \mathbb{K}^{m \times n}$.
- Finite signal: $x = (x_0, \dots, x_{N-1}) \in \mathbb{K}^N$.
- Sample rate: $f_s \in \mathbb{R}_{>0}$.
- Norms: $\|\cdot\|_2$ for vectors and spectral matrix norm unless another norm is displayed.
- Adjoint: $A^* = \overline{A}^{\mathsf{T}}$.
- Machine comparison scale: $s(a, b) = \max(1, \|a\|, \|b\|)$.
- Numerical acceptance predicate:

$$\operatorname{close}_\tau(a, b) \iff \|a - b\| \leq \tau\, s(a, b), \qquad \tau \geq 0.$$

- `close_tau` is guide notation only, not a universal implementation comparator. Each API card must reproduce the source comparator's exact norm, scaling, strictness, multiplier, fixed internal tolerance, and validation behavior. Implementations include scaled and absolute residuals, strict lower bounds, fixed internal tolerances, and branches that return an invalid certificate rather than applying one uniform tolerance rule.

VI.0.2 Claim labels

- **E**: exact finite combinatorics, indexing, shape law, or algebra over exact inputs.
- **N**: finite numerical result checked against an explicit tolerance.
- **C**: conditional mathematical statement with user-declared assumptions.
- **H**: heuristic, estimator, or data-dependent discovery rule.
- **M**: declared cost or traffic model, not an observed runtime theorem.
- **O**: optional backend whose import, runtime, and device execution are separate facts.
- **I**: integrity or deterministic identity record.

VI.0.3 Canonical return distinction

- Plain value: $y = f(x)$.
- Certified value: `ComputationResult[T] = (value: T, certificate: Certificate)`.
- Diagnostic record: finite observations without a theorem claim.
- Conditional certificate:

$$\mathcal{C} = (v, e, R, \tau, A_\checkmark, A_?, D, T, m),$$

where v is validity, e exactness, R residuals, τ tolerance, $A_\checkmark$ checked assumptions, $A_?$ unchecked assumptions, D diagnostics, T theorem identifier, and m message.

VI.0.4 Coverage routing

- Chapters 28 through 30: every public symbol in `algorithms.layout`, `ir`, `structured`, `low_rank`, `support`, `krylov`, `precision`, `compiler`, `scheduling`, `complexity`, `discovery`, `gpu`, and `benchmarks`.
- Chapters 31 through 36A: every public symbol in the twenty `signals` modules listed in the source inventory.
- Compatibility aliases are documented at the canonical implementation card and indexed separately.
- Internal `_validation` helpers are contributor material, not supported user imports.

VI.0.5 Package controls and compatibility aliases

- Algorithms namespace controls: `algorithms.FEATURE_KEY = "algorithms"`. `algorithms.status()` returns that registered feature specification. `algorithms.require()` is the implemented-namespace compatibility no-op and returns `None`.
- Signals namespace controls: `signals.FEATURE_KEY = "signals"`. `signals.status()` returns that registered feature specification.
- Exact compatibility aliases:

$$\texttt{FinitePolyphaseKernel} = \texttt{PolyphaseBlockMatrix},$$
$$\texttt{finite_polyphase_filter_kernels} = \texttt{finite_polyphase_blocks}.$$

- Recovery routing aliases: `VectorJumpRecoveryResult` is `signals.edge_recovery.JumpRecoveryResult`. `recover_vector_jumps` is `signals.edge_recovery.recover_jumps`. `recover_vector_jumps_subgaussian` is `signals.edge_recovery.recover_jumps_subgaussian`.
- Singular-packet aliases:

$$\texttt{RetainedPacketReconstruction} = \texttt{RetainedPacketResult},$$
$$\texttt{TruncatedPowerPacket} = \texttt{TruncatedPowerTerm}.$$

- `shannon_entropy_cost(coefficients, path="")` is a compatibility wrapper that calls `entropy_cost(coefficients, path)`. Document behavioral equivalence without claiming object identity.

VI.0.6 Duplicate-name import resolution

- Package import `komorebi_math.signals.polyphase_convolution` resolves to `signals.convolution.polyphase_convolution(signal, kernel, order, *, mode="full", tolerance=1e-11)`, the finite convolution-mode API.
- Module import `komorebi_math.signals.polyphase.polyphase_convolution(signal, kernel, order)` is a distinct full-convolution coordinate function and is not separately re-exported under another package-level name.
- Package import `komorebi_math.signals.finite_difference` resolves to `signals.recovery.finite_difference(values, *, order=1, step=1)`.
- `komorebi_math.signals.singular_packets.finite_difference(signal, order=1)` remains module-public but is not package-re-exported.
- Package `haar_step_coefficient(amplitude, support_length, relative_location)` comes from `signals.recovery`.
- Package `step_haar_coefficient(amplitude, relative_location, interval_length)` comes from `signals.edge_recovery`. The distinct names preserve the distinct argument orders.

---

28. Packet intermediate representation

28.0 Chapter contract

- Goal: encode $A : X \to Y$ by finite packet blocks with explicit layout, support, storage, arithmetic, and execution semantics.
- Exact layer: packet names, sizes, slices, addresses, graph relations, and structural composition.
- Numerical layer: block values, thresholded omission, materialized equality, and floating certificates.
- Central warning: structural support is an upper inclusion because different block paths may cancel numerically.

28.1 `PacketLayout`: typed packet coordinate spaces

Let

$$X = \bigoplus_{s=0}^{p-1} X_s, \qquad \dim X_s = n_s > 0, \qquad n = \sum_{s=0}^{p-1} n_s.$$

- Constructor data: `sizes = (n_0,...,n_{p-1})`, optional unique nonempty `names`. - Derived offsets:

$$o_0 = 0, \qquad o_{s+1} = o_s + n_s, \qquad I_s = [o_s, o_{s+1}).$$

- `dimension = n`, `offsets = (o_0,...,o_p)`, `slices = (I_0,...,I_{p-1})`. - `index : (int | str) -> {0,...,p-1}`. - `packet_slice(s) = I_s`. `packet_size(s)=n_s`. - Split and merge:

$$\mathrm{split}_X : \mathbb{K}^{n \times r} \to \prod_s \mathbb{K}^{n_s \times r}, \qquad \mathrm{merge}_X((x_s)_s) = \mathrm{concat}_s\, x_s.$$

- Tensor crossing with $Y = \bigoplus_t Y_t$:

$$X \boxtimes Y = \bigoplus_{s,t} (X_s \otimes Y_t), \qquad \dim(X_s \otimes Y_t) = n_s m_t.$$

- Packet permutation $\pi \in S_p$ induces coordinate index vector

$$P_\pi = (I_{\pi(0)}, I_{\pi(1)}, \dots, I_{\pi(p-1)}).$$

- Failure cards: empty layout, noninteger or nonpositive size, duplicate or empty name, missing names, invalid packet key, invalid permutation, wrong split leading dimension, mixed vector/matrix packets, incompatible RHS counts.

28.2 `PacketIR`: block-typed finite operators

For source layout $X = \bigoplus_s X_s$ and target layout $Y = \bigoplus_t Y_t$, define

$$A_{ts} = Q_t A P_s \in \mathbb{K}^{m_t \times n_s}, \qquad (t,s) \in \Sigma(A).$$

- Address order is always `(target, source)`. - Type:

$$\mathrm{PacketIR}[X,Y] = \{A_{ts} : X_s \to Y_t\}_{(t,s)\in\Sigma(A)}.$$

- Shape: $(\sum_t m_t, \sum_s n_s)$. - Dtype: result type of active block dtypes, or floating default for empty support. - Support: $\Sigma(A) = \{(t,s) : A_{ts} \text{ stored}\}$. - Storage:

$$S(A) = \sum_{(t,s)\in\Sigma(A)} S(A_{ts}).$$

- Batched application:

$$y_t = \sum_{s:(t,s)\in\Sigma(A)} A_{ts} x_s, \qquad y = \mathrm{merge}_Y((y_t)_t).$$

- Materialization:

$$\mathrm{mat}(A)[I_t, I_s] = A_{ts},$$

with addition if a representation ever contributes more than once to a dense region. - `from_dense` threshold:

$$\theta = \tau_{\mathrm{abs}} + \tau_{\mathrm{rel}} \|A\|_2, \qquad (t,s) \text{ retained} \iff \|A[I_t, I_s]\|_2 > \theta,$$

unless `keep_zeros=True`. - Adjoint:

$$(A^*)_{st} = A^*_{ts}, \qquad \Sigma(A^*) = \{(s,t) : (t,s) \in \Sigma(A)\}.$$

- Composition $C = A \circ B$:

$$C_{ts} = \sum_u A_{tu} B_{us}, \qquad \Sigma(C) \subseteq \Sigma(A) \circ \Sigma(B).$$

- Composition pruning is numerical when `atol > 0`:

$$C_{ts} \text{ stored} \iff \|C_{ts}\|_2 > \tau_{\mathrm{compose}}.$$

- Powers by binary exponentiation, with $A^0 = I_X$. - Tensor:

$$(A \otimes B)_{(t,u),(s,v)} = A_{ts} \otimes B_{uv}.$$

- Packet diagonal:

$$D(A) = \bigoplus_s A_{ss},$$

defined only when source and target layouts agree. - Certificate residual:

$$r_{\mathrm{IR}} = \|A(I_n) - \mathrm{mat}(A)\|, \qquad r_{\mathrm{IR}} \le \tau.$$

- Failure cards: out-of-range address, malformed address, block shape mismatch, incompatible composition layouts, non-square power, negative exponent, negative/nonfinite tolerance, incompatible RHS.

28.3 Structural support algebra

- Relation product:

$$L \circ R = \{(t,s) : \exists u\ (t,u) \in L \wedge (u,s) \in R\}.$$

- `support_power` has no ambient `vertex_count`. Its zero power is

$$\mathrm{support_power}(\Sigma, 0) = \{(v,v) : v \text{ occurs in an edge of } \Sigma\}.$$

  Thus empty support has empty zero power. For $k \ge 1$, `support_power` recursively forms $\Sigma^k = \Sigma \circ \Sigma^{k-1}$.

- In contrast, `support_polynomial(..., vertex_count=q)` inserts the full q-vertex identity when the constant coefficient is nonzero, and `PacketIR.power(0)` constructs the full identity on its packet layout.
- Polynomial inclusion for $p(A) = \sum_{k=0}^{d} c_k A^k$:

$$\Sigma(p(A)) \subseteq \bigcup_{k:c_k \neq 0} \Sigma(A)^k.$$

- Transitive closure: $\Sigma^* = I \cup \Sigma \cup \Sigma^2 \cup \cdots$ on a finite vertex set.
- Acyclic unit-diagonal inverse inclusion:

$$(I - N)^{-1} = I + N + \cdots + N^{q-1}, \qquad \Sigma((I - N)^{-1}) \subseteq \Sigma(N)^*.$$

- Schur fill for retained R and hidden H: retain direct $R \to R$ edges and every path $R \to H \to \cdots \to H \to R$.
- `topological_levels` returns executable DAG layers $(L_0, \ldots, L_d)$.
- `longest_path_vertices` returns the maximum vertex count on a directed path.
- `SupportGraph.targets`, `sources`, `reachable`, `is_acyclic`, and `closure` receive separate mini-cards.
- Failure cards: vertex outside range, retained-hidden overlap, noncontiguous partition, cyclic inverse request, cyclic topological request.

28.4 Cost and memory symbols

For dense active block support Σ, batch size r, and scalar size b bytes:

$$F_{\text{packet}} = 2r \sum_{(t,s)\in\Sigma} m_t n_s, \qquad S_{\text{packet}} = \sum_{(t,s)\in\Sigma} m_t n_s.$$

One-pass no-cache-reuse traffic model:

$$B_{\text{stream}} = b \sum_{(t,s)\in\Sigma} (m_t n_s + n_s r + 2 m_t r).$$

Arithmetic intensity and elementary roofline lower bound:

$$I = F/B, \qquad T_{\min} = \max(F/P_{\max}, B/W_{\max}).$$

- Status: counts are **E/M** under the declared dense-block model. The roofline number is **M**, not measured latency. - `CostEstimate` stores flops, scalar storage, traffic, intensity, optional roofline seconds, and metadata. - Failure cards: negative/nonfinite rates, one missing device rate, invalid support, nonpositive item size or RHS count.

28.5 Benchmark contract and observational timing

- Timing scopes: kernel, device-resident, end-to-end.
- Matched contract:

$$\mathfrak{B} = (\text{case signature}, \text{output contract}, \text{scope}, \text{backend}).$$

- Comparison is permitted only if signatures, output contracts, and scopes match. Backend equality is optional by policy.
- Observations:

$$\tilde{t} = \text{median}(t_1, \ldots, t_R), \qquad \text{speedup} = \tilde{t}_{\text{baseline}}/\tilde{t}_{\text{candidate}}.$$

- Synchronization occurs before and after timed device calls when supplied.
- Status: all timing claims are **H/O** and environment-bound.

28.6 Example specifications

EX-28-A: layout roundtrip

- Input: $n = (2, 1, 3)$, names (a, b, c), $X \in \mathbb{R}^{6\times 2}$. Construct: `PacketLayout`, `split`, `merge`, `crossed`, `permutation`. Assert: $\text{merge}(\text{split}(X)) = X$. Negative case: duplicate name or wrong leading dimension.

EX-28-B: IR execution and support cancellation

- Input: two compatible packet layouts and blocks A_{tu}, B_{us}. Compute: $C = A \circ B$, materialized reference $\widehat{C} = \text{mat}(A)\,\text{mat}(B)$. Verify: $\|\text{mat}(C) - \widehat{C}\| \le \tau$. Adversary: choose two paths with opposite products so the structural edge exists but the dense block vanishes.

EX-28-C: modeled versus observed performance

- Build: one sparse packet IR and its dense materialization. Report: $(F, S, B, I, T_{\text{min}})$ separately from benchmark samples. Refuse: compare timing records with different transfer/setup scopes.

---

29. Structured and low-rank operators

29.0 Common structured operator protocol

Every `StructuredOperator` card specifies

$$A : \mathbb{K}^n \to \mathbb{K}^m, \quad A : \mathbb{K}^{n\times r} \to \mathbb{K}^{m\times r},$$

plus `shape`, `dtype`, `apply`, `materialize`, `adjoint`, `storage_entries`, `flop_count`, optional `solve`, and `certificate_residual`. - Default solve is dense and square:

$$x = \text{solve}(\text{mat}(A), b).$$

- The protocol preserves vector-versus-matrix RHS rank. - A cost method is a declared model and must not be described as a benchmark.

29.1 Dense, identity, diagonal, and block diagonal

- `DenseOperator(M)`: $Ax = Mx$, storage mn, modeled flops $2mnr$.
- `IdentityOperator(n,c)`:

$$A = cI_n, \quad S = 1, \quad F = nr, \quad A^{-1} = c^{-1}I_n \ (c \neq 0).$$

- `DiagonalOperator(d)`:

$$Ax = d \odot x, \quad S = n, \quad F = nr, \quad A^{-1}x = d^{-1} \odot x.$$

- `BlockDiagonalOperator(A_0,...,A_{p-1})`:

$$A = \bigoplus_s A_s, \quad Ax = \bigoplus_s A_s x_s, \quad A^{-1} = \bigoplus_s A_s^{-1}.$$

- Failure cards: nonmatrix dense input, zero scalar solve, zero diagonal entry, empty block list, nonsquare block, incompatible RHS.

29.2 Circulant, Toeplitz, Kronecker, and Walsh-Hadamard

- Circulant first column $c \in \mathbb{K}^n$:

$$C_{ij} = c_{(i-j) \bmod n}, \qquad Cx = \mathcal{F}_n^{-1}(\mathcal{F}_n(c) \odot \mathcal{F}_n(x)).$$

- Modeled circulant work: $10n\lceil \log_2 \max(2, n)\rceil r$. Storage n.
- Rectangular Toeplitz $T \in \mathbb{K}^{m\times n}$ is specified by first column and row with common corner.
- `ToeplitzOperator` accepts the common corner through NumPy `allclose`, so constructor acceptance is a numerical corner-consistency guard rather than exact scalar equality.

- Toeplitz application uses a circulant embedding of length $m+n$, with storage $m+n-1$.
- Kronecker factors $L \in \mathbb{K}^{a\times b}$, $R \in \mathbb{K}^{c\times d}$:

$$(L \otimes R)\,\mathrm{vec}_F(X) = \mathrm{vec}_F(RXL^{\mathsf{T}}), \quad X \in \mathbb{K}^{d\times b}.$$

- Walsh-Hadamard dimension $n = 2^q$: butterfly recursion

$$(u, v) \mapsto (u+v, u-v), \qquad H_n^{-1} = n^{-1}H_n,$$

  or $H_n^{-1} = H_n$ in normalized mode.
- Failure cards: empty first column, Toeplitz corner mismatch, nonmatrix Kronecker factor, non-power-of-two Hadamard dimension.

29.3 Low-rank operators and recompression

- `LowRankOperator(U,V)`:

$$A = UV^*, \quad U \in \mathbb{K}^{m\times k}, \quad V \in \mathbb{K}^{n\times k}, \quad \mathrm{rank}(A) \le k.$$

- Apply:

$$Ax = U(V^*x), \quad S = k(m+n), \quad F = 2kr(m+n).$$

- Core recompression input:

$$A = LCR^*, \quad L \in \mathbb{K}^{m\times p}, \quad C \in \mathbb{K}^{p\times q}, \quad R \in \mathbb{K}^{n\times q}.$$

- Reduced QR and small SVD:

$$L = Q_L R_L, \quad R = Q_R R_R, \quad R_L C R_R^* = U\Sigma V^*.$$

- Rank-k factors:

$$\widetilde{U} = Q_L U_k \Sigma_k^{1/2}, \qquad \widetilde{V} = Q_R V_k \Sigma_k^{1/2}.$$

- In exact arithmetic, the Eckart-Young rank-truncation optimum has tail diagnostics

$$\|A - \widetilde{U}\widetilde{V}^*\|_2 = \sigma_{k+1}, \qquad \|A - \widetilde{U}\widetilde{V}^*\|_F = \Big(\sum_{j>k} \sigma_j^2\Big)^{1/2}.$$

- The returned singular values, factors, and residual comparison are NumPy numerical realizations, and the source certificate has `Exactness.NUMERICAL`.
- Numerical certificate checks actual spectral residual against the SVD tail plus scaled tolerance.
- Empty-factor branch returns a valid rank-zero correction.

29.4 Block diagonal plus low rank and Woodbury

Let

$$A = D + UV^*, \qquad D = \bigoplus_s D_s.$$

- Storage model:

$$S = \sum_s n_s^2 + 2nk.$$

- Apply model:

$$F = 2r\sum_s n_s^2 + 4nkr.$$

- Woodbury solve:

$$(D+UV^*)^{-1}b = D^{-1}b - D^{-1}U(I + V^*D^{-1}U)^{-1}V^*D^{-1}b.$$

- Preconditions: each block of D solvable and small middle matrix nonsingular. - Exact product representation is formed before optional recompression. - Repeated local recompression recurrence:

$$E_j \le \|A_j\|E_{j-1} + e_j.$$

- Telescoping product bound for exact A_j and approximate $\widetilde{A}_j$:

$$\Big\|\widetilde{A}_{q-1}\cdots\widetilde{A}_0 - A_{q-1}\cdots A_0\Big\| \le \sum_{j=0}^{q-1}\Big(\prod_{i>j}\|\widetilde{A}_i\|\Big)\|\widetilde{A}_j - A_j\|\Big(\prod_{i<j}\|A_i\|\Big).$$

29.5 Restricted structure discovery

- Packet threshold discovery in a fixed layout:

$$\theta = \tau_a + \tau_r \|A\|_2, \qquad \widehat{\Sigma} = \{(t,s) : \|A_{ts}\|_2 > \theta\}.$$

- Status: **H/N**. A discarded block is not proved algebraically zero.
- Diagnostic: $\|A - \widehat{A}\|_2$.
- BDLR discovery:

$$D = \text{blockdiag}(A), \qquad R = A - D, \qquad R_k = \text{SVD}_k(R), \qquad \widehat{A} = D + R_k.$$

- In exact arithmetic, fixed-layout BDLR discovery inherits fixed-rank SVD optimality for the residual. Returned factors, singular values, and error diagnostics are NumPy numerical realizations. Status is **N**.
- Failure cards: layout mismatch, invalid rank, nonfinite threshold, instability when $\|A_{ts}\| \approx \theta$.

29.6 Example specifications

EX-29-A: structured operator gallery

- Choose one vector x and construct dense, diagonal, circulant, Toeplitz, Kronecker, and Hadamard operators. Compare `apply(x)` with `materialize() @ x`. Tabulate shape, stored entries, modeled flops, and numerical residual separately.

EX-29-B: Woodbury and recompression

- Input: invertible block diagonal D, factors U, V, RHS b. Verify: $\|(D+UV^*)x - b\| \le \tau$. Compress: rank $k \to r < k$. Report σ_{r+1}, Frobenius tail, actual residual. Negative case: singular diagonal block or singular Woodbury middle matrix.

EX-29-C: threshold sensitivity

- Sweep $\theta_- < \|A_{ts}\| < \theta_+$. Display support discontinuity and continuous discarded norm. State explicitly that discovery is heuristic even when its finite residual is certified.

---

30. Krylov, precision, compilation, and scheduling

30.0 Krylov operator protocol

- Matrix-free callable:

$$\mathcal{A} : \mathbb{K}^n \to \mathbb{K}^n.$$

- Callable shape preservation is checked on every generated vector.
- Global Hermitian or positive-definite behavior is not inferred from finitely many directions.

30.1 Krylov bases

For nonzero $b \in \mathbb{K}^n$:

$$\mathcal{K}_k(A, b) = \text{span}\{b, Ab, \dots, A^{k-1}b\}.$$

- Modified Gram-Schmidt constructs $Q_k \in \mathbb{C}^{n \times d}$, $d \le k$. - Breakdown:

$$\|v_j - \sum_{i<j} q_i (q_i^* v_j)\| \le \tau_{\text{krylov}}.$$

- Certificate:

$$r_{\text{orth}} = \|Q_k^* Q_k - I_d\|, \qquad r_{\text{orth}} \le 100 \tau_{\text{krylov}}.$$

- Failure cards: zero start relative to tolerance, steps outside $[1, n]$, changed callable output dimension.

30.2 Preconditioned conjugate gradients

Declared system:

$$Ax = b, \qquad A = A^* > 0, \qquad M = M^* > 0.$$

- Stop threshold:

$$\tau_{\text{stop}} = \max(\tau_{\text{abs}}, \tau_{\text{rel}}\|b\|_2).$$

- Initialization:

$$r_0 = b - Ax_0, \quad z_0 = M^{-1}r_0, \quad p_0 = z_0.$$

- Recurrence:

$$\alpha_k = \frac{r_k^* z_k}{p_k^* A p_k}, \quad x_{k+1} = x_k + \alpha_k p_k, \quad r_{k+1} = r_k - \alpha_k A p_k,$$

$$z_{k+1} = M^{-1}r_{k+1}, \quad \beta_k = \frac{r_{k+1}^* z_{k+1}}{r_k^* z_k}, \quad p_{k+1} = z_{k+1} + \beta_k p_k.$$

- Generated-direction checks: near-real pairings and positive curvature above numerical floor. - Certificate reports true final residual and recursive residual. - Unchecked assumption: global Hermitian positive definiteness. - Failure cards: non-Hermitian generated pairing, negative curvature, nonpositive preconditioner pairing, nonfinite recurrence, iteration limit.

30.3 Lanczos and Ritz data

- Fully reorthogonalized recurrence:

$$Aq_j = \beta_{j-1}q_{j-1} + \alpha_j q_j + \beta_j q_{j+1}.$$

- Projected tridiagonal:

$$T_k = Q_k^* A Q_k = \text{tridiag}(\beta_{j-1}, \alpha_j, \beta_j).$$

- Certificate residuals:

$$r_{\text{orth}} = \|Q_k^* Q_k - I\|, \qquad r_{\text{tri}} = \|Q_k^* A Q_k - T_k\|.$$

- Ritz values are $\lambda(T_k)$. No unqualified global eigenvalue accuracy claim.
- Failure card: materially complex $q_j^* A q_j$ signals non-Hermitian behavior.

30.4 Block Jacobi certificate

Let $D = \text{blockdiag}(A)$ and

$$E = D^{-1/2}(A - D)D^{-1/2}, \qquad \eta = \|E\|_2.$$

If $A = A^*$, every diagonal block is positive definite, and $\eta < 1$, then

$$\kappa(D^{-1/2}AD^{-1/2}) \le \frac{1+\eta}{1-\eta}.$$

- Record: `BlockJacobiCertificate(diagonal, normalized_coupling, eta, condition_bound, certificate).` - `block_jacobi_preconditioner(D)` is the exact packet-block solve callable. - Power perturbation:

$$\|A^k - B^k\| \le k \max(\|A\|, \|B\|)^{k-1}\|A - B\|.$$

- Failure cards: non-Hermitian input, nonpositive packet block, $\eta \ge 1$, shape/layout mismatch.

30.5 Continuous precision allocation

For sensitivities $s_i > 0$, costs $c_i > 0$, and total error budget $T > 0$:

$$\min_{\varepsilon_i > 0} \sum_i c_i \log(1/\varepsilon_i) \quad \text{s.t.} \quad \sum_i s_i \varepsilon_i \le T.$$

- Unclipped solution:

$$\varepsilon_i^* = \frac{T c_i}{s_i \sum_j c_j}.$$

- With maxima $0 < \varepsilon_i \le u_i$:

$$\varepsilon_i(\lambda) = \min\left(u_i, \frac{c_i}{\lambda s_i}\right), \qquad \sum_i s_i \varepsilon_i(\lambda) = T.$$

- Packet perturbation bound:

$$\|\Delta y\| \le \sum_i \|\Delta A_i\| \|x_i\|.$$

- Certificate compares observed error with the bound plus τ.

30.6 Discrete precision and quantization

- Packet i has finite options $d \in \mathcal{D}_i$ with cost c_{id} and integer error units e_{id}.
- Exact finite dynamic program:

$$\min_{d_i \in \mathcal{D}_i} \sum_i c_{i,d_i} \quad \text{s.t.} \quad \sum_i e_{i,d_i} \le B.$$

- Return `None` for infeasible budget, not a false certificate.
- Complex arrays cast to the complex partner of a real target dtype.
- Quantization diagnostic:

$$e_q(x, d) = \| \operatorname{cast}_d(x) - x \|_p.$$

- Failure cards: empty option list, duplicate option names, invalid dtype, negative error units/cost/budget, value/dtype list mismatch.

30.7 Exact tree compilation

At node v: keep pair (c_v, e_v), split overhead s_v, children $\mathrm{ch}(v)$. - Lagrangian recursion:

$$J_v^{\text{keep}} = c_v + \lambda e_v, \qquad J_v^{\text{split}} = s_v + \sum_{u \in \mathrm{ch}(v)} J_u^*, \qquad J_v^* = \min(J_v^{\text{keep}}, J_v^{\text{split}}).$$

- Budget compiler quantizes each selected leaf independently:

$$q_v = \lceil e_v / u \rceil, \qquad \sum_{v \in L} q_v \le B.$$

- Pareto frontier contains nondominated (c, e) plans. Positive tolerance alters tie semantics. - Enumeration cap `max_plans` is a resource guard. - Decision margin:

$$\Delta_v = |J_v^{\text{keep}} - J_v^{\text{split}}|.$$

- Multiple objectives with shared named topology:

$$(c_v, e_v, s_v) = \sum_j w_j (c_{v,j}, e_{v,j}, s_{v,j}).$$

- Failure cards: duplicate node names, topology mismatch, unknown update, negative/nonfinite model value, frontier explosion.

30.8 Scheduling and amortization

- Task DAG $G = (V, E)$, duration $d_v \geq 0$.
- Unlimited-concurrency earliest start:

$$t_v^{\text{start}} = \max_{u \to v} t_u^{\text{finish}}, \qquad t_v^{\text{finish}} = t_v^{\text{start}} + d_v.$$

- Makespan is weighted critical-path length.
- Shape batching ideal launch count:

$$L_{\text{batch}} = |\{\text{shape keys}\}|, \quad L_{\text{no batch}} = |V|.$$

- Setup amortization with setup S, baseline per-use b, candidate per-use c:

$$q_{\min} = \left\lfloor \frac{S}{b - c} \right\rfloor + 1 \quad \text{when } b > c,$$

  otherwise no finite break-even count.
- Status: schedule is **E** for declared durations. Performance meaning is **H/M**.
- Failure cards: unknown dependency, duplicate task, self-dependency, directed cycle, unhashable shape key.

30.9 NumPy and optional CuPy execution

- `NumpyPacketExecutor`: host input, host output, PacketIR semantics.
- `CupyPacketExecutor`: blocks materialized and transferred once at construction.
- Device apply options distinguish `input_on_device` and `return_host`.
- `cupy_available()` means module discoverability only.
- Hardware qualification requires import success, CUDA runtime, device count, synchronized execution, CPU parity, and environment record.
- GPU certificate does not claim synchronized timing unless synchronization is explicitly in the benchmark contract.
- Failure cards: CuPy absent, runtime/device error, unknown backend, wrong RHS shape.

30.10 Example specifications

EX-30-A: block-Jacobi CG

- Construct HPD A, packet layout, D, and η. Solve with and without preconditioning. Report residual histories and bound $(1 + \eta)/(1 - \eta)$. Negative case: perturb a generated direction to negative curvature.

EX-30-B: precision pipeline

- Input: sensitivities s_i, costs c_i, maxima u_i, dtypes $\mathcal{D}_i$, budget B. Compare continuous allocation, clipped allocation, exact discrete assignment, and observed quantization error. Negative case: infeasible integer budget.

EX-30-C: compiler-to-schedule

- Compile a finite packet tree, turn selected leaves into a task DAG, schedule it, group shape keys, and compute setup break-even. Preserve the distinction between exact decisions and modeled durations.

EX-30-D: CPU/GPU matched contract

- Create identical case signatures and output contracts. Execute CPU always. Execute GPU only if runtime-qualified. Verify numerical parity before presenting timing. Negative case: refuse kernel-only versus end-to-end comparison.

---

31. Signal conventions, windows, and framing

31.0 Stable signal conventions

- Signal-first convention: first convolution argument is signal, second is kernel.
- Time axis is the only axis for one-dimensional DSP routines.
- Nonemptiness, dimensionality, and finiteness checks are transcribed per function. The package does not impose one universal finite-entry guard across all signal APIs.
- Spectral, filtering, recursive, FFT-convolution, resampling, adaptive, and streaming paths explicitly reject nonfinite samples. Framing/STFT, direct convolution, several filter-bank paths, polyphase paths, and recovery paths do not uniformly call `isfinite` on every signal entry.
- Real input may produce complex transforms. Inverse routines use `real_if_close` only after computation.
- `same` output always has signal length N, beginning at full-convolution index $\lfloor (K-1)/2 \rfloor$, even when $K > N$.
- Boundary choices are mathematical data, not formatting options.

31.1 Deterministic windows

For $n = 0, \dots, N-1$: - Boxcar: $w_n = 1$. - Hann: $w_n = \frac{1}{2} - \frac{1}{2}\cos(2\pi n/(N-1))$. - Hamming: $w_n = 0.54 - 0.46\cos(2\pi n/(N-1))$. - Blackman:

$$w_n = 0.42 - 0.5\cos\theta_n + 0.08\cos(2\theta_n), \quad \theta_n = 2\pi n/(N-1).$$

- Bartlett, Kaiser $w(\beta)$, and Tukey $w(\alpha)$ receive formula boxes. - Periodic convention constructs the symmetric length $N+1$ window and drops the last sample. - Explicit array windows must already have length N and finite entries.

31.2 Window metrics

For $w \in \mathbb{K}^N$, $W_0 = \sum_n w_n \neq 0$:

$$G_c = |W_0|/N, \qquad G_p = \frac{1}{N}\sum_n |w_n|^2,$$

$$\mathrm{ENBW}_{\mathrm{bins}} = \frac{N\sum_n |w_n|^2}{|W_0|^2}, \qquad \mathrm{ENBW}_{\mathrm{Hz}} = \frac{f_s}{N}\,\mathrm{ENBW}_{\mathrm{bins}}\,.$$

- Failure cards: zero coherent gain for ENBW, nonfinite samples, nonpositive sample rate.

31.3 Overlap profiles and canonical duals

For hop $H \leq N$ and residue $r \in \{0, \dots, H-1\}$:

$$p_r^{(2)} = \sum_{n \equiv r\ (H)} |w_n|^2, \qquad p_r^{(1)} = \sum_{n \equiv r\ (H)} w_n.$$

- NOLA: $\min_r |p_r^{(2)}| > \tau \max(1, \max_r |p_r^{(2)}|)$. - COLA: $\max_r |p_r - p_0| \leq \tau \max(1, \max_r |p_r|)$. - Condition diagnostic:

$$\kappa_{\mathrm{overlap}} = \max_r |p_r| / \min_r |p_r|.$$

- Canonical dual:

$$\widetilde{w}_n = \frac{\overline{w_n}}{p^{(2)}_{n \bmod H}}, \qquad \sum_k w_{n-kH}\widetilde{w}_{n-kH} = 1.$$

- Infinite-lattice certificate leaves finite-record boundary coverage unchecked.

31.4 Deterministic framing

Given signal length N, frame length L, hop $H \le L$:

$$s_m = mH, \qquad F_{m,n} = x^{\text{pad}}_{s_m+n}, \quad 0 \le n < L.$$

- Centering adds $\lfloor L/2 \rfloor$ samples on both sides. - `pad_end=False` retains complete frames only. - `pad_end=True` appends the minimum right padding needed for the last complete frame. - Boundary modes: zeros, reflect, edge, none. - Frame record shapes:

$$F \in \mathbb{K}^{M \times L}, \quad s \in \mathbb{Z}^M, \quad s_m = mH.$$

- Covered length: $(M-1)H + L$. Padded length: $N + p_L + p_R$. - Exact framing certificate checks shape, starts, and coverage inclusion.

31.5 Overlap-add synthesis primitive

For frames F_m and optional synthesis window v:

$$y[n] = \sum_m F_m[n - mH]v[n - mH].$$

- Output length: $(M-1)H + L$. - Optional `length` may crop but not exceed represented range. - This primitive does not normalize by an analysis/synthesis denominator. Normalized STFT inversion is Chapter 32.

31.6 Example specification

EX-31-A: window/framing truth table

- Evaluate seven window families under symmetric and periodic conventions. Tabulate $G_c, G_p, \text{ENBW}, p^{(1)}, p^{(2)}$. Frame one signal under every boundary choice and show exact starts/padding. Negative cases: reflect with one sample, `boundary='none'` when padding is required, hop greater than frame length, zero-overlap dual request.

---

32. Time-frequency and spectral analysis

32.0 STFT typed map

For $x \in \mathbb{K}^N$, frame count M, FFT length $K \ge L$:

$$\text{STFT}_{w,H,K} : \mathbb{K}^N \to \mathbb{C}^{M \times F},$$

where $F = K$ for two-sided output and $F = \lfloor K/2 \rfloor + 1$ for real one-sided output.

32.1 STFT definition and coordinates

$$X[m,k] = \sum_{n=0}^{L-1} x^{\text{pad}}[mH + n]w[n]e^{-2\pi ikn/K}.$$

- Default hop: $H = \max(1, \lfloor L/4 \rfloor)$. - Physical frequencies: $f_k = kf_s/K$ in one-sided order or NumPy signed order. - Frame-center times:

$$t_m = \frac{mH + L/2 - p_L}{f_s}.$$

- `detrend='constant'` subtracts each frame mean before windowing. - One-sided mode rejects complex input. - Metadata is sufficient for normalized inversion.

32.2 Normalized inverse STFT

Let v be the synthesis window and $\widehat{F}_m$ the inverse FFT frame. Define

$$a[n] = \sum_m \widehat{F}_m[n - mH]v[n - mH],$$

$$d[n] = \sum_m w[n - mH]v[n - mH], \qquad \hat{x}[n] = a[n]/d[n].$$

- Validity on the requested unpadded interval requires

$$\min_n |d[n]| > \tau \max(1, \max_n |d[n]|).$$

- Certificate residual:

$$r_{\text{norm}} = \max_n |\hat{x}[n]d[n] - a[n]|.$$

- Source roundtrip is a separate certificate:

$$r_{\text{rt}} = \|\hat{x} - x\|_2 \le \tau \max(1, \|x\|_2).$$

- Failure cards: destructive constant detrending, zero local overlap denominator, requested output beyond original or represented range.

32.3 Spectrogram scalings

For $Z = |X|$: - Magnitude: $S_{\text{mag}} = Z$. - Power: $S_{\text{power}} = Z^2$. - Density:

$$S_{\text{density}} = \frac{Z^2}{f_s \sum_n |w_n|^2}.$$

- Spectrum:

$$S_{\text{spectrum}} = \frac{Z^2}{|\sum_n w_n|^2}.$$

- One-sided power-like scalings double interior bins, excluding DC and even-length Nyquist. - Failure card: spectrum scaling with zero coherent gain.

32.4 Periodogram and Welch PSD

- Modified periodogram:

$$P_{xx}[k] = \frac{|\mathcal{F}_K((x - \text{trend}(x))w)[k]|^2}{D_w},$$

  where $D_w = f_s \sum |w|^2$ for density and $|\sum w|^2$ for spectrum.
- `periodogram` constructs named windows with `get_window(..., periodic=False)`.
- Welch:

$$\widehat{P}_{xx}[k] = \text{Avg}_{m=0}^{M-1} P_{xx}^{(m)}[k],$$

  with mean or median averaging. `welch_psd` constructs named windows with `get_window(..., periodic=True)`.
- `cross_spectrum` also uses `periodic=True`. Its complex median is formed by taking separate medians of real and imaginary parts, with no statistical median-bias correction.
- Frequency resolution:

$$\Delta f = f_s/K.$$

- Integrated density: $\sum_k P[k]\Delta f$. Integrated spectrum: $\sum_k P[k]$.
- Status: finite computations **N**, stochastic consistency and variance claims **H/C**.

32.5 Cross spectra, coherence, and H1 transfer

For paired frame transforms $X_m[k], Y_m[k]$:

$$P_{xx} = \operatorname{Avg} |X_m|^2 / D_w, \quad P_{yy} = \operatorname{Avg} |Y_m|^2 / D_w,$$

$$P_{xy} = \operatorname{Avg}(\overline{X_m} Y_m) / D_w.$$

With ridge $\rho \geq 0$:

$$\gamma^2[k] = \frac{|P_{xy}[k]|^2}{(P_{xx}[k] + \rho)(P_{yy}[k] + \rho)}, \qquad H_1[k] = \frac{P_{xy}[k]}{P_{xx}[k] + \rho}.$$

- Returned coherence is clipped to $[0, 1]$, while the certificate records pre-clipping bound excess. - Unchecked: linear time-invariant data generation and statistical consistency.

32.6 Parseval certificate

Under NumPy DFT normalization:

$$\sum_{n=0}^{N-1} |x_n|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X_k|^2.$$

- Residual uses scaled tolerance. - Both real and complex signals must be examples.

32.7 Streaming STFT

- Mutable state: bounded buffer, buffer start, next frame start, total accepted samples, closed flag.
- `process(chunk)` emits all newly complete frames.
- `flush(pad_end=True)` emits at most the terminal zero-padded frame and closes.
- Post-flush processing is invalid. Repeated flush emits an empty batch.
- Chunk-invariance theorem:

  $$\operatorname{concat}_j \operatorname{streamSTFT}(x^{(j)}) = \operatorname{STFT}(x), \qquad x = x^{(0)} \| \cdots \| x^{(q-1)},$$

  for matching uncentered, zero-terminal-padding conventions.
- Certificate separately records coefficient and timestamp residuals.

32.8 Example specifications

EX-32-A: invertible chirp STFT

- Input: deterministic chirp x, Hann w, $H = L/4$, centered frames. Compute: STFT, canonical or default dual, inverse, spectrogram. Verify: local denominator, normalized identity, source roundtrip. Negative case: constant detrending followed by inverse request.

EX-32-B: spectral transfer experiment

- Generate $y = h * x + \varepsilon$ with fixed seed. Estimate $P_{xx}, P_{yy}, P_{xy}, \gamma^2, H_1$. Compare estimated H_1 with known FIR response only as a finite diagnostic. Show low-input-power bins and ridge sensitivity.

EX-32-C: adversarial chunks

- Partition the same signal into one-sample, prime-length, empty-process, and final partial chunks. Verify concatenated streaming frames equal batch frames. Negative case: chunk sizes do not sum to signal length.

---

33. Filtering and convolution

33.0 Finite convolution conventions

For signal $x \in \mathbb{K}^N$ and kernel $h \in \mathbb{K}^K$:

$$(h * x)[n] = \sum_{j=0}^{K-1} h[j]x[n-j].$$

- The public mode aliases are distinct:

$$\texttt{ConvolutionMode} = \{\texttt{full}, \texttt{same}, \texttt{valid}, \texttt{circular}\},$$

$$\texttt{FIRMode} = \{\texttt{causal}, \texttt{full}, \texttt{same}, \texttt{valid}\}.$$

- Full, common to both: length $N + K - 1$. - Causal, FIR-only: length N, indices $0{:}N$ of full output. - Same, common to both: length N, start $\lfloor (K-1)/2 \rfloor$. - Valid, common to both: length $\max(N - K + 1, 0)$, start $K - 1$. - Circular, convolution-only: length N, with source index $(n - j)$ mod N. - `convolution_matrix`, `convolution_output_length`, `convolve_signal`, and finite `PolyphaseConvolution` consume `ConvolutionMode`. They do not accept `causal`. - `fir_filter`, `fft_convolve`, `overlap_add_convolve`, and `certified_overlap_add_convolve` consume `FIRMode`. They do not accept `circular`.

33.1 Convolution matrices and finite polyphase blocks

- Matrix type:

$$H_h^{\text{mode}} \in \mathbb{K}^{M \times N}, \qquad y = H_h^{\text{mode}} x.$$

- Residue source and target indices for order q:

$$I_s^X = \{s, s+q, s+2q, \ldots\} \cap [0, N),$$

$$I_t^Y = \{t, t+q, t+2q, \ldots\} \cap [0, M).$$

- Finite transfer blocks:

$$H_{ts} = H_h^{\text{mode}}[I_t^Y, I_s^X].$$

- Coordinate application:

$$y_t = \sum_s H_{ts} x_s.$$

- Certificate compares reconstructed packet output with $H_h x$.
- Infinite causal zero-extended kernels $h[qm + t - s]$ must not be substituted for finite boundary blocks without proving boundary equivalence.

33.2 FIR response and windowed-sinc design

- FIR transfer:

$$H(e^{i\omega}) = \sum_{n=0}^{K-1} h_n e^{-i\omega n}.$$

- Ideal low-pass seed at cutoff f_c:

$$h_n^{\text{ideal}} = 2\frac{f_c}{f_s}\,\text{sinc}\left(2\frac{f_c}{f_s}\left[n - \frac{K-1}{2}\right]\right).$$

- High-pass and band-stop use spectral inversion. Band-pass is a low-pass difference.
- Final taps: $h_n = h_n^{\text{ideal}} w_n$, optionally normalized at the declared reference frequency.
- Odd tap count is required by this implementation's linear-phase construction.
- Group delay: $(K-1)/2$ samples.
- FIR certificate:

$$r_{\text{sym}} = \max_n |h_n - h_{K-1-n}|, \qquad r_{\text{gain}} = \left||H(f_{\text{ref}})| - g_{\text{ref}}\right|.$$

- Failure cards: cutoff outside $(0, f_s/2)$, unordered band, wrong cutoff arity, even tap count, zero normalization gain.

33.3 Streaming FIR

- State contains the most recent $K-1$ input samples.
- `process` emits one causal output for every accepted sample.
- `flush` emits the remaining $K-1$ full-convolution samples exactly once.
- `reset` restores zero history and reopens the stream.
- Chunk-invariance certificate:

$$\operatorname{concat}_j \operatorname{process}(x^{(j)}) = \operatorname{fir_filter}(x, h, \operatorname{causal}).$$

- The wrapper certificate excludes the full tail unless `flush` is included explicitly in the example.

33.4 Recursive FIR/IIR filters

Normalized rational transfer:

$$H(z) = \frac{\sum_{j=0}^{q} b_j z^{-j}}{1 + \sum_{j=1}^{q} a_j z^{-j}}.$$

- Direct-form II transposed state $s \in \mathbb{K}^q$:

$$y_n = b_0 x_n + s_0,$$

$$s_j \leftarrow s_{j+1} + b_{j+1} x_n - a_{j+1} y_n, \quad s_{q-1} \leftarrow b_q x_n - a_q y_n.$$

- Constructor divides numerator and denominator by a_0, then zero-pads to common order. - Zeros and poles are roots of numerator and denominator coefficient polynomials. - Strict BIBO pole certificate:

$$r_{\max} = \max_{\lambda \in \text{poles}} |\lambda|, \qquad 1 - r_{\max} > \tau.$$

- Biquad parameters:

$$\omega_0 = 2\pi f_0 / f_s, \qquad \alpha = \sin \omega_0 / (2Q),$$

with low-pass, high-pass, band-pass, notch, and all-pass numerator tables. - Streaming recursion transports the final state exactly between chunks and certifies batch equality. - Failure cards: $a_0 = 0$, state dimension mismatch, singular response denominator, invalid f_0 or Q, unstable poles.

33.5 FFT and overlap-add convolution

- Zero-padded FFT length:

$$L_{\text{FFT}} = 2^{\lceil \log_2 (N+K-1) \rceil}.$$

- Linear convolution:

$$y = \mathcal{F}^{-1}_{L_{\text{FFT}}} \left(\mathcal{F}(x) \odot \mathcal{F}(h) \right)_{0:N+K-1}.$$

- Overlap-add block length B uses FFT size

$$L_B = 2^{\lceil \log_2 (B+K-1) \rceil}.$$

- Mutable state: precomputed kernel spectrum, untransformed input buffer, $K-1$ overlap samples, complex-mode flag, closed flag.
- Certificate:

$$r_{\text{OLA}} = \|y_{\text{OLA}} - y_{\text{direct}}\|_\infty \le \tau \max(1, \|y_{\text{direct}}\|_\infty).$$

- NumPy FFT is the implemented backend here. GPU claims belong only to separately qualified executor paths.

33.6 Example specifications

EX-33-A: all convolution modes

- Choose $K > N$ intentionally. Print $H_h^{\text{full,same,valid,circular}}$ shapes and outputs. Verify matrix, direct finite, FFT, overlap-add, and polyphase implementations under matching modes. Highlight the stable signal-length `same` convention.

EX-33-B: FIR and IIR streaming

- Design one FIR and one stable biquad. Process identical irregular chunks, retain state, flush where applicable. Verify batch equivalence and plot response metadata later. Negative cases: processing after FIR flush and an unstable IIR denominator.

---

34. Resampling and adaptive filters

34.0 Rational rate normalization

For requested integers $u, d > 0$:

$$g = \gcd(u, d), \qquad U = u/g, \qquad D = d/g.$$

- All plan metadata uses the reduced ratio U/D. - Output length:

$$N_{\text{out}} = \left\lceil \frac{NU}{D} \right\rceil = \left\lfloor \frac{NU + D - 1}{D} \right\rfloor.$$

34.1 Primitive upsampling and downsampling

- Upsampling:

$$(\uparrow_U x)[n] = \begin{cases} x[n/U], & n \equiv 0 \pmod U, \\ 0, & \text{otherwise.} \end{cases}$$

- Downsampling with phase r:

$$(\downarrow_{D,r} x)[m] = x[r + mD], \qquad 0 \le r < D.$$

- `interpolate` is filtered $(U, 1)$. `decimate` is filtered $(1, D)$.

34.2 Centered rational resampling plan

- Default odd tap count: $K = 20 \max(U, D) + 1$.
- Upsampled-grid cutoff:

$$f_c = \frac{1}{2 \max(U, D)} \quad \text{cycles per high-rate sample.}$$

- Windowed sinc taps are scaled to

$$\sum_{j=0}^{K-1} h_j = U.$$

- Center delay: $\delta = (K - 1)/2$.
- Polyphase components: $h^{(r)} = (h_r, h_{r+U}, \ldots)$, $0 \le r < U$.
- Direct plan formula for output m:

$$q_m = \delta + mD, \qquad r_m = q_m \bmod U,$$

$$y_m = \sum_{j \equiv r_m \ (U)} h_j x_{(q_m - j)/U},$$

where out-of-range source indices are omitted by zero extension.

- Explicit reference: zero insertion, full convolution, remove delay, decimate by D.
- Certificate residuals:

$$r_{\text{poly}} = \|y_{\text{plan}} - y_{\text{explicit}}\|_\infty, \qquad r_{\text{DC}} = |\sum_j h_j - U|.$$

- Unchecked: application-specific alias rejection and boundary transient acceptability.
- Failure cards: even tap count, invalid phase, zero DC gain, nonpositive ratio, nonfinite signal.

34.3 Adaptive filtering state model

Given input x_n, desired d_n, and tap count p:

$$u_n = (x_n, x_{n-1}, \dots, x_{n-p+1})^{\mathsf{T}}, \qquad y_n = w_n^* u_n, \qquad e_n = d_n - y_n.$$

- Output shapes:

$$y, e \in \mathbb{K}^N, \quad w_N \in \mathbb{K}^p, \quad W_{\text{hist}} \in \mathbb{K}^{(N+1)\times p}.$$

- Result diagnostics:

$$\text{MSE} = N^{-1} \sum_n |e_n|^2, \qquad \text{tailMSE}_\rho = |I_\rho|^{-1} \sum_{n \in I_\rho} |e_n|^2.$$

34.4 LMS and NLMS

- Leaky LMS:

$$w_{n+1} = (1 - \mu\lambda) w_n + \mu u_n \overline{e_n}, \qquad \mu > 0,\ \lambda \geq 0.$$

- NLMS denominator and update:

$$g_n = \varepsilon + u_n^* u_n, \qquad w_{n+1} = \left(1 - \frac{\mu\lambda}{g_n}\right) w_n + \frac{\mu}{g_n} u_n \overline{e_n},$$

  with $\varepsilon > 0$.
- Finite certificate asserts only finite recursion and parameter ranges.
- Unchecked: persistent excitation, independence model, and convergence for the chosen step.

34.5 RLS

With forgetting $0 < \gamma \leq 1$ and initial inverse covariance $P_0 = \delta I$, $\delta > 0$:

$$k_n = \frac{P_n u_n}{\gamma + u_n^* P_n u_n},$$

$$w_{n+1} = w_n + k_n \overline{e_n}, \qquad P_{n+1} = \gamma^{-1} \left(P_n - k_n u_n^* P_n\right).$$

- Implementation symmetrizes $P_{n+1} \leftarrow (P_{n+1} + P_{n+1}^*)/2$. - Diagnostic records maximum Hermitian residual. - `AdaptiveFilterResult.certificate.theorem_id` is currently `KM-DSP-D12` for LMS, NLMS, and RLS. This is the field actually returned, although function provenance identifiers are respectively `KM-DSP-D12`, `KM-DSP-D13`, and `KM-DSP-D14`. Flag the latter two as a source metadata inconsistency rather than silently rewriting the certificate. - Failure cards: vanished gain denominator, invalid forgetting factor, nonpositive initialization, unequal input/desired length.

34.6 Chunk invariance matrix

The guide should cross-reference these state laws: - FIR: $K - 1$ input-history state. - IIR: direct-form state $s \in \mathbb{K}^q$. - STFT: overlap/unframed sample buffer. - Overlap-add: transform buffer plus convolution overlap. - Rational resampler: currently a finite batch plan, not a mutable streaming API. - Adaptive filters: currently finite batch recurrences with complete weight history, not a chunked state class. This distinction prevents examples from promising streaming APIs that are not implemented.

34.7 Example specifications

EX-34-A: coprime and reducible resampling

- Compare requests $(u, d) = (6, 4)$ and reduced $(3, 2)$. Verify identical plan ratio, output length, polyphase components, explicit reference, and DC gain. Inspect a tone only as a finite alias diagnostic.

EX-34-B: system identification

- Generate fixed-seed input and desired output from known w_*. Run LMS, NLMS, RLS from common zero weights. Report $\|w_N - w_*\|$, MSE, tail MSE, and certificate assumptions. Negative cases: no excitation, excessive step, and forgetting outside $(0, 1]$.

---

35. Filter banks, wavelets, and packet trees

35.0 Periodic analysis/synthesis matrices

For periodic length N divisible by decimation D, channel filters h_c, g_c:

$$A_c = \downarrow_D C_{h_c} \in \mathbb{K}^{(N/D)\times N}, \qquad S_c = C_{g_c} \uparrow_D \in \mathbb{K}^{N\times(N/D)}.$$

- Stacked analysis and synthesis:

$$A = \begin{bmatrix} A_0 \\ \vdots \\ A_{C-1} \end{bmatrix}, \qquad S = \begin{bmatrix} S_0 & \cdots & S_{C-1} \end{bmatrix}.$$

- Reconstruction:

$$\hat{x} = SAx.$$

- Perfect reconstruction certificate:

$$r_{\text{PR}} = \|SA - I_N\|_2 \le \tau.$$

- Frame bounds from singular values of A:

$$\alpha = \sigma_{\min}(A)^2, \qquad \beta = \sigma_{\max}(A)^2.$$

- The source reports the square of NumPy's smallest returned singular value. It is a genuine positive lower frame bound on $\mathbb{K}^N$ only when A has full column rank, hence its row count is at least N. For an undercomplete A, the mathematical lower frame bound is zero even when NumPy's smallest returned nonzero singular value is positive. - `PeriodicFilterBank.frame_bounds` and `FiniteFilterBank.report` do not append the missing zero singular values in the undercomplete case. - Canonical synthesis: $S_{\text{can}} = A^\dagger$. `PeriodicFilterBank.canonical_synthesis_matrix` returns the pseudoinverse without separately enforcing perfect reconstruction.

35.1 General finite filter banks

For analysis $E \in \mathbb{K}^{m\times n}$ and synthesis $R \in \mathbb{K}^{n\times m}$: - `analyze(x)=Ex`. `synthesize(c)=Rc`. Reconstruction RE. - Canonical dual requires $\operatorname{rank}(E) = n$, then $R = E^\dagger$. - Thus `FiniteFilterBank.canonical_dual` enforces full column rank, while the singular-value output in `FiniteFilterBank.report` is only the source's reported diagnostic until that rank condition is established. - Perturbation bound for $\widetilde{E} = E + \Delta E$, $\widetilde{R} = R + \Delta R$:

$$\|\widetilde{R}\widetilde{E} - I\| \le \|RE - I\| + \|\Delta R\|\|E\| + \|R\|\|\Delta E\| + \|\Delta R\|\|\Delta E\|.$$

- Failure cards: incompatible matrix shapes, rank-deficient canonical-dual request, mismatched perturbation shape.

35.2 Haar analysis and synthesis

For even/odd pair (x_{2j}, x_{2j+1}):

$$a_j = \frac{x_{2j} + x_{2j+1}}{c}, \qquad d_j = \frac{x_{2j} - x_{2j+1}}{c},$$

with $c = \sqrt{2}$ normalized and $c = 1$ unnormalized. - Synthesis uses denominator $\sqrt{2}$ normalized or 2 unnormalized. - Normalized energy identity:

$$\|x\|_2^2 = \|a\|_2^2 + \|d\|_2^2.$$

- Failure card: odd signal length or unequal channel shape.

35.3 Periodic lifting

With circular predict P and update U:

$$d = x_o - Px_e, \qquad s = x_e + Ud.$$

- Exact inverse algebra:

$$x_e = s - Ud, \qquad x_o = d + Px_e.$$

- Periodic 5/3 floating scheme uses predict $(1/2, 1/2)$ and update $(1/4, 1/4)$. - Certificate checks finite roundtrip under the periodic boundary convention.

35.4 Haar packet trees

- Path alphabet: $\{0, 1\}$, root ϵ, depth J.
- Node coefficient c_p splits into c_{p0}, c_{p1}.
- Signal length requirement: $2^J \mid N$.
- A pruning L is valid iff it is prefix-free and every full-depth path has exactly one selected ancestor.
- Reconstruction recursively merges selected leaves.
- Normalized pruning energy:

$$\|x\|_2^2 = \sum_{p \in L} \|c_p\|_2^2.$$

- Failure cards: invalid path character, ancestor and descendant both selected, incomplete cover, excessive depth.

35.5 Exact additive best basis

For node cost $C(p, c_p)$:

$$B(p) = \min\left(C(p, c_p), B(p0) + B(p1)\right).$$

- Tie policy: keep node when costs are equal. - Margin:

$$\Delta_p = |C(p, c_p) - B(p0) - B(p1)|.$$

- Entropy cost:

$$C_{\text{ent}}(c) = -\sum_{j : q_j > 0} q_j \log q_j, \qquad q_j = |c_j|^2 / \sum_{\ell} |c_\ell|^2.$$

- Positive-power cost:

$$C_p(c) = \sum_j |c_j|^p, \qquad p > 0.$$

- Optimization is **E** for the supplied finite costs. Floating cost evaluation remains numerical data.

35.6 Multilevel Haar denoising

- Decomposition depth J requires $2^J \mid N$.
- MAD and Gaussian scale estimate:

$$\mathrm{MAD}(d) = \mathrm{median}\,|d - \mathrm{center}(d)|, \qquad \hat{\sigma} = \mathrm{MAD}(d_1)/0.6744897501960817.$$

- Universal threshold:

$$\lambda = \hat{\sigma}\sqrt{2\log n}.$$

- SURE chooses among observed coefficient magnitudes using its finite risk array.
- Shrinkage maps:

$$T_{\mathrm{hard}}(z) = z\mathbf{1}_{|z|\geq\lambda},$$

$$T_{\mathrm{soft}}(z) = z\frac{\max(|z| - \lambda, 0)}{|z|},$$

$$T_{\mathrm{garrote}}(z) = z\frac{\max(|z|^2 - \lambda^2, 0)}{|z|^2},$$

  with zero-safe denominators.
- Finite certificate checks reconstruction finiteness and shrinkage magnitude monotonicity.
- Noise-model optimality remains unchecked.
- Observed risk certificate with known clean reference:

$$\mathrm{MSE}(\hat{x}, x) \leq \mathrm{MSE}(y, x) + \tau.$$

  This is a finite comparison, not a population risk theorem.

35.7 Example specifications

EX-35-A: redundant canonical dual

- Construct tall analysis $E \in \mathbb{R}^{m\times n}$, $m > n$. Compute frame bounds, canonical dual, PR residual, and perturbation bound. Negative case: remove rank and reject the canonical dual.

EX-35-B: packet best basis

- Build depth-J Haar packet tree. Compare full leaves, entropy best basis, and ℓ^p best basis. Verify pruning, reconstruction, energy, decisions, and margins.

EX-35-C: denoising claims ladder

- Fixed seed, clean piecewise-smooth signal, additive noise. Compare threshold rules and modes. Separate: decomposition certificate, shrinkage certificate, observed clean-reference risk, and unproved stochastic generalization.

---

36. Singular packets and recovery

36.0 Singular packet model

For finite components (ξ_j, a_j, r_j), $r_j \in \mathbb{Z}_{\geq 0}$:

$$j(x) = \sum_{j=1}^{J} a_j \frac{(x-\xi_j)_+^{r_j}}{r_j!}.$$

- `TruncatedPowerTerm(location, amplitude, order)` is one component. - `SingularPacket1D` is a finite sum. - At order zero, the implementation uses $\mathbf{1}_{x\geq\xi}$. - `trace_jumps` groups derivative-jump amplitudes by location and order. - `remove(f, x)=f-j(x). restore(g,x)=g+j(x).`

36.1 Location perturbation bounds

- Equal-amplitude steps:

$$\|a\mathbf{1}_{x\geq\xi} - a\mathbf{1}_{x\geq\hat{\xi}}\|_{L^p} = |a|\,|\xi-\hat{\xi}|^{1/p},$$

  and $|a|$ in L^∞ when displacement is nonzero.
- Positive-order mean-value bound on interval $[L, R]$:

$$\|a(\cdot-\xi)_+^r/r! - a(\cdot-\hat{\xi})_+^r/r!\|_{L^p} \leq \frac{|a|S^{r-1}}{(r-1)!}|\xi-\hat{\xi}|(R-L)^{1/p},$$

  with $S = \max(0, R - \min(\xi, \hat{\xi}))$.

36.2 Deterministic separated-jump recovery

Samples:

$$y_i = g(x_i) + j(x_i) + \eta_i, \qquad x_i = x_0 + ih.$$

Declared bounds:

$$\mathrm{Lip}(g) \leq M, \qquad |\eta_i| \leq \varepsilon, \qquad |a_j| \geq a_{\min}.$$

- Adjacent contrast background:

$$B = Mh + 2\varepsilon.$$

- Required separation:

$$a_{\min} > 2B.$$

- Valid threshold interval:

$$B < \theta < a_{\min} - B.$$

- Detect cell i when $|y_{i+1} - y_i| > \theta$. - Report midpoint location $x_i + h/2$, contrast amplitude, location error bound $h/2$, amplitude error bound B. - Scalar and vector forms use absolute value or Euclidean contrast norm. - Conditional assumptions remain unchecked because samples alone do not prove true smoothness, noise bounds, minimum jump, or one jump per cell.

36.2.1 Scalar and scalar/vector API split

- `signals.recovery.JumpRecoveryResult`, exported at package level as `JumpRecoveryResult`, stores `detections`, `threshold`, `background_bound`, `location_error_bound`, `amplitude_error_bound`, and `certificate`. `.cells`, `.locations`, and `.amplitudes` are derived properties.
- `recover_separated_jumps(samples, *, spacing, lipschitz_bound, noise_bound, minimum_jump, threshold=None, start=0.0, minimum_separation=None)` is the scalar API. It raises `AssumptionError` when the finite minimum-jump gap, threshold interval, or declared minimum-separation check fails.
- Its probabilistic wrapper is package-level `recover_jumps_subgaussian(samples, *, spacing, lipschitz_bound, sigma, delta, minimum_jump, threshold=None, start=0.0, minimum_separation=None)`.
- `signals.edge_recovery.JumpRecoveryResult`, exported at package level as `VectorJumpRecoveryResult`, stores `cells`, `locations`, `amplitudes`, `contrasts`, `threshold`, `background_bound`, `location_error_bound`, `amplitude_error_bound`, and `certificate` directly. `.packet()` is defined only when the amplitude array is one-dimensional. Vector amplitudes raise `ValidationError`.

- `signals.edge_recovery.recover_jumps`, exported as `recover_vector_jumps(samples, *, spacing, lipschitz_bound, noise_bound, minimum_jump, origin=0.0, threshold=None)`, accepts scalar or (N, D) sample arrays. A failed finite theorem gap returns a conditional certificate with `valid=False` rather than raising solely for that gap.
- Its probabilistic package alias is `recover_vector_jumps_subgaussian(samples, *, spacing, lipschitz_bound, sigma, minimum_jump, failure_probability, origin=0.0)` and applies to scalar or vector sample matrices.

36.3 Sub-Gaussian recovery

- Scalar simultaneous contrast scale:

$$B_\eta = 2\sigma\sqrt{\log(2N/\delta)}.$$

- Vector coordinate union-bound scale with D coordinates and $N-1$ cells:

$$b_{\text{coord}} = 2\sigma\sqrt{\log(2\max(N-1,1)D/\delta)},$$

$$B_\eta = \sqrt{D}\, b_{\text{coord}}.$$

- Claimed probability is at least $1-\delta$ only under independent centered sub-Gaussian coordinate assumptions.
- Certificate must display the probability model among unchecked assumptions.

36.4 Haar coefficient diagnostics

- Smooth Lipschitz contribution over support length L:

$$|\langle g, \psi_L\rangle| \le ML^{3/2}/4.$$

- Step of amplitude a at relative position $u \in [0,1]$:

$$|\langle a\mathbf{1}_{x\ge\xi}, \psi_L\rangle| = |a|\sqrt{L}\min(u, 1-u).$$

- Half-shift helper compares a point with grid and half-grid boundaries. Its exact implementation returns the larger of the two nearest-boundary distances.
- These formulas motivate localization but do not replace the recovery hypotheses.

36.5 Piecewise-polynomial breakpoint bands

- Forward difference with step s:

$$(\Delta_s x)_n = x_{n+s} - x_n, \qquad \Delta_s^q = \Delta_s \circ \cdots \circ \Delta_s.$$

- Degree-d segments vanish under Δ^{d+1} away from breakpoints.
- Uniform sample noise ε amplifies to

$$B_{d+1} = 2^{d+1}\varepsilon.$$

- Detection threshold must satisfy $\theta \ge B_{d+1}$.
- Output is a band of response indices, not automatically a unique breakpoint location.

36.6 Retained and estimated reconstruction

For exact retained packet j, smooth part $g = f - j$, and approximator Q:

$$\hat{f} = Q(f-j) + j = Qg + j,$$

$$f - \hat{f} = g - Qg.$$

For estimated packet $\hat{j}$ and linear matrix Q:

$$\hat{f} = Q(f-\hat{j}) + \hat{j}, \qquad f - \hat{f} = (I-Q)(f-\hat{j}).$$

If $f = g + j$:

$$f - \hat{f} = (I-Q)g + (I-Q)(j-\hat{j}).$$

- Certificates check these algebraic decompositions numerically. - Supplying only one of `true_smooth` and `true_packet` is invalid.

36.7 Exact region-error formulas

For true scalar value a, estimate b, overlap measure μ_I, true-only μ_T, estimate-only μ_E:

$$\|a\mathbf{1}_T - b\mathbf{1}_E\|_p^p = |a-b|^p\mu_I + |a|^p\mu_T + |b|^p\mu_E.$$

For labeled partitions with overlap matrix $M_{ij} = \mu(T_i \cap E_j)$:

$$\|f - \hat{f}\|_p = \left(\sum_{i,j} M_{ij}|a_i - b_j|^p\right)^{1/p}.$$

- $p = \infty$ takes the largest active mismatch. - Empirical mask/label wrappers compare formula against direct finite-array norm. - Failure cards: negative overlap, incompatible labels, value index outside table, invalid p.

36.8 Failure cases that must remain conditional

- Two jumps inside one cell can cancel an adjacent contrast.
- Adjacent active cells violate the separated-cell hypothesis.
- A wrong Lipschitz or noise bound invalidates theorem interpretation even if code executes.
- Low-amplitude jumps below the contrast gap are not recoverable by this theorem.
- A breakpoint band need not identify an exact physical breakpoint.
- Packet estimation error can dominate smooth approximation error when $(I-Q)(j-\hat{j})$ is large.

36.9 Example specifications

EX-36-A: scalar recovery with full claim ledger

- Construct g with known Lipschitz constant, separated steps, and bounded deterministic noise. Compute B, threshold interval, cells, midpoint locations, amplitudes, and bounds. Verify true locations/amplitudes only because synthetic truth is available. Negative cases: $a_{\min} = 2B$, adjacent steps, two cancelling steps in one cell.

EX-36-B: retained reconstruction identity

- Choose exact j, estimated $\hat{j}$, and projection Q. Display smooth error and packet error terms separately. Verify both reconstruction identities and an exact step-location L^p error.

36A. Approximation, nonlinear packet products, and Smith charts

36A.1 Fourier low-pass approximation

- One-dimensional integer mode mask:

$$\hat{x}_k^{(M)} = \hat{x}_k\mathbf{1}_{|k|\le M}, \qquad x^{(M)} = \mathcal{F}^{-1}(\hat{x}^{(M)}).$$

- Two-dimensional rectangular centered mask:

$$\widehat{X}_{k,\ell}^{(M)} = \widehat{X}_{k,\ell}\mathbf{1}_{|k-k_0|\le M}\mathbf{1}_{|\ell-\ell_0|\le M}.$$

- Status: deterministic finite approximation **N**.
- A discontinuous input example must show Gibbs ringing rather than imply universal edge preservation.

36A.2 Otsu and positive-packet estimation

For histogram class probability $\omega(t)$ and cumulative mean $\mu(t)$:

$$\sigma_B^2(t) = \frac{(\mu_T\omega(t) - \mu(t))^2}{\omega(t)(1-\omega(t))}.$$

- Otsu selects a finite bin center maximizing σ_B^2. - Positive packet mask: $M_i = \mathbf{1}_{x_i > t}$. - Amplitude heuristic: median selected minus median unselected. - Status: **H**. Model assumes one dominant positive contrast. No universal edge theorem. - Counterexamples: negative contrast, multiple regions, heavy gradient, and histogram-bin instability.

36A.3 Coefficient packets and cyclic products

- Residue-supported sequence packets:

$$a_n^{(r)} = a_n \mathbf{1}_{n \equiv r \pmod q}, \qquad a = \sum_{r=0}^{q-1} a^{(r)}.$$

- Product routing:

$$c^{(t)} = \sum_{r+s \equiv t \ (q)} a^{(r)} * b^{(s)}.$$

- Compact channels require carry

$$t = (r+s) \bmod q, \qquad \kappa = \lfloor (r+s)/q \rfloor,$$

  which shifts the coarse convolution by κ.
- Certificate reconstructs the direct Cauchy product.
- Mixed flat/compact representations are rejected.

36A.4 Nonlinear shift filters

- Typed implementation map:

$$F : \mathbb{R}^N \to \mathbb{R}^N.$$

- `nonlinear_shift_filter` coerces the signal with `dtype=float`. Generalized shift indices and coefficients are converted to Python numeric scalars, so this API is real-only rather than a generic $\mathbb{K}$-valued transform.
- Legacy map:

$$y = x + \alpha x \odot R_s x.$$

- Generalized map:

$$y = x + \alpha x \odot \left(\sum_j c_j R_{s_j} x \right),$$

  where R_s is cyclic `roll`.
- Status: finite numerical polynomial transform. No stability theorem is attached.
- `packet_product`, by contrast, supports complex coefficient arrays.
- Failure cards: mismatched or empty shift/coefficient lists, non-one-dimensional input.

36A.5 Smith/Cayley coordinates

- Normalized impedance to reflection coefficient:

$$\Gamma = \frac{Z-1}{Z+1}, \qquad Z \neq -1.$$

- Inverse:

$$Z = \frac{1+\Gamma}{1-\Gamma}, \qquad \Gamma \neq 1.$$

- Cyclic phase $\zeta = e^{2\pi ip/q}$ acts as disk rotation $\Gamma \mapsto \zeta\Gamma$, pulled back to

$$Z \mapsto \frac{(1+\zeta)Z + (1-\zeta)}{(1-\zeta)Z + (1+\zeta)}.$$

- Regularized sensitivity diagnostic:

$$S_\rho(\Gamma) = \frac{1}{|1-\Gamma|^2 + \rho} + \frac{1}{|1+\Gamma|^2 + \rho}, \qquad \rho \geq 0.$$

- The exact exclusions $Z = -1$, $\Gamma = 1$, and a vanishing phase-map denominator describe the rational formulas. The implemented practical domains are narrower because `gamma_from_impedance`, `impedance_from_gamma`, and `phase_mobius` reject denominators that NumPy `isclose` regards as zero.
- `smith_sensitivity` rejects negative regularization, but does not explicitly reject nonfinite regularization. Preserve this source behavior in the failure card rather than implying a stronger finite-value guard.
- Singular and near-singular numerical chart boundaries must be shown explicitly.

36A.6 Example specifications

EX-36A-A: approximation versus retained packets

- Apply Fourier low-pass directly to a step signal. Estimate or supply a singular packet, remove it, low-pass the remainder, and restore it. Compare direct approximation error, retained-packet error, and packet-estimation term without claiming universal superiority.

EX-36A-B: cyclic product and Smith action

- Verify compact packet carry routing against direct polynomial multiplication. Roundtrip several complex impedances through $Z \leftrightarrow \Gamma$. Apply all q cyclic phases and inspect sensitivity near $\Gamma = \pm 1$.

VI.R Exhaustive reference-card and example requirements

VI.R.1 Per-symbol card schema

Every public symbol covered by this expansion receives: 1. Canonical import and API tier. 2. Typed signature with scalar field and array shapes. 3. Definition or recurrence. 4. Preconditions and dimension constraints. 5. Boundary, axis, normalization, and dtype conventions. 6. Exact, numerical, conditional, heuristic, model, optional, or integrity label. 7. Tolerance scaling and certificate residuals. 8. Return record fields, properties, and mutable state where relevant. 9. Failure modes and exact exception family. 10. Backend behavior and optional-dependency isolation. 11. Storage, arithmetic, traffic, or state budget when defined. 12. Minimal success example, adversarial failure example, and related symbols.

VI.R.2 Algorithms module ledger

- `algorithms` package controls: `FEATURE_KEY`, `status()`, and `require()`.
- `algorithms.layout`: `PacketLayout` and every public constructor, property, and transform.
- `algorithms.ir`: `Address`, `PacketIR`, dense import, block access, execution, adjoint, composition, power, tensor, diagonal, certificate.
- `algorithms.structured`: protocol plus dense, identity, diagonal, block-diagonal, circulant, Toeplitz, Kronecker, Walsh-Hadamard, adapter.
- `algorithms.low_rank`: low-rank factors, recompression records/functions, BDLR algebra, Woodbury solve, product and accumulated error bounds.
- `algorithms.support`: relation product/power/polynomial, closure, acyclic inverse, Schur fill, levels, longest path, `SupportGraph`.
- `algorithms.krylov`: basis, CG, Lanczos, block-Jacobi certificate/preconditioner, condition and power bounds.
- `algorithms.precision`: continuous/clipped allocation, discrete options/assignment, quantization, error/certificate.

- `algorithms.compiler`: nodes/plans, two exact compilers, Pareto frontier, combined objectives, margins, immutable update.
- `algorithms.scheduling`: task records, unlimited schedule, shape grouping, launch count, break-even, verification.
- `algorithms.complexity`: every arithmetic, storage, traffic, intensity, roofline, and aggregate estimate function.
- `algorithms.discovery`: support and BDLR discovery result cards and the heuristic-versus-optimal distinction.
- `algorithms.gpu`: availability, execution results, CPU/CuPy executors, synchronization, backend factory.
- `algorithms.benchmarks`: timing scope, contract, result, comparison, measurement, matched comparison.

VI.R.3 Signals module ledger

- `signals` package controls: `FEATURE_KEY` and `status()`. Package aliases and duplicate-name routing follow §§VI.0.5 through VI.0.6.
- `signals.windows`: all window specifications, metrics, profiles, NOLA/COLA certificate, canonical dual.
- `signals.time_frequency`: boundary/detrend/scaling aliases, frame records, framing, overlap-add, STFT/inverse, spectrogram records/functions.
- `signals.streaming`: streaming STFT batch/state/wrapper and all public counters/properties.
- `signals.spectral`: power/cross records, periodogram, Welch, cross spectrum, Parseval.
- `signals.filtering`: FIR aliases, response, designs, application, streaming state/wrapper.
- `signals.recursive`: biquad alias, output/filter/state records, recursion, design, streaming wrapper.
- `signals.convolution`: modes, lengths, matrices, direct application, finite polyphase records/functions.
- `signals.fft_convolution`: FFT convolution, overlap-add state, batch and certified wrappers.
- `signals.resampling`: lengths, primitive samplers, design, plan/result records, rational/interpolation/decimation functions.
- `signals.adaptive`: method alias, result diagnostics, LMS, NLMS, RLS.
- `signals.filterbanks`: periodic/Haar/lifting/general banks, reports, matrices, convenience constructors, perturbation and reconstruction tools.
- `signals.wavelets`: path/cost aliases, complete/pruned tree records, best basis, costs, analysis/synthesis/energy.
- `signals.denoise`: threshold aliases, MAD/noise/threshold functions, decomposition/result records, denoiser, observed risk certificate.
- `signals.recovery`: scalar detections/results, separated/sub-Gaussian recovery, differences, breakpoint records, Haar formulas.
- `signals.edge_recovery`: scalar/vector result, recovery functions, Haar and half-shift helpers.
- `signals.singular_packets`: canonical classes and aliases, reconstruction records/functions, region/overlap errors, differences/noise bound.
- `signals.approximation`: 1-D/2-D Fourier truncation, Otsu, positive-packet record/estimator.
- `signals.nonlinear`: coefficient packets, cyclic product, nonlinear shift filter.
- `signals.smith`: Cayley maps, phase Möbius map, sensitivity.
- `signals.polyphase`: referenced finite coordinate, lattice, kernel, convolution, mixed-radix, and roundtrip cards required by Chapters 33 and 35.

VI.R.4 Required connected tutorials

- `T-VI-1`: dense matrix → layout → PacketIR → support graph → cost estimate.
- `T-VI-2`: structure discovery → BDLR approximation → recompression → Woodbury solve.
- `T-VI-3`: block-Jacobi certificate → CG → precision plan → task schedule.
- `T-VI-4`: window → frame → STFT → inverse → streaming equivalence.
- `T-VI-5`: FIR design → batch/stream/FFT/OLA/polyphase execution → spectral verification.
- `T-VI-6`: rational resampling → adaptive identification → finite diagnostic comparison.
- `T-VI-7`: filter bank → Haar packet tree → best basis → denoising.
- `T-VI-8`: jump recovery → singular packet → retained approximation → exact region-error decomposition.
- `T-VI-9`: negative-example atlas covering every assumption, shape, tolerance, boundary, singularity, unavailable backend, and resource-limit branch above.

VI.R.5 Editorial completion gates

- No timing claim without a benchmark contract and recorded environment.
- No GPU claim from module discovery alone.
- No exact label on FFT, SVD, eigensolve, pseudoinverse, or floating reconstruction.
- No theorem claim from a heuristic threshold or empirical risk comparison.
- No streaming claim for a batch-only API.
- No infinite convolution law substituted for a finite boundary convention.
- No conditional recovery guarantee without displaying unchecked hypotheses.
- Every worked example prints or explains its certificate rather than only asserting `.valid`.
- Every negative example identifies whether failure is a validation error, dimension error, assumption error, backend-unavailable error, zero division, or linear-algebra failure.
- Every prose chapter is cross-linked to the exhaustive API appendix and at least one executable example.

86. Nonlinear systems and dynamics

Specifications for nonlinear calculus and finite dynamics

> These specifications supplement Chapters 37 through 46. Every identity retains its exact, numerical, conditional, heuristic, optional, or integrity-only classification.

VII.0 Common notation and writing contract

Let

$$F : X \to Y, \qquad X \cong \mathbb{K}^{d_X}, \qquad Y \cong \mathbb{K}^{d_Y}, \qquad D^r F(x)[v_1, \dots, v_r] \in Y.$$

Let finite packet resolutions be

$$I_X = \sum_{a \in A} P_a, \qquad I_Y = \sum_{b \in B} Q_b.$$

Claim labels used throughout:

- **E**: exact finite algebra or combinatorics.
- **N**: numerical finite-dimensional identity with tolerance.
- **C**: conditional conclusion with visible unchecked assumptions.
- **H**: heuristic, estimator, or observational profile.
- **O**: optional framework or hardware path.
- **I**: integrity or reproducibility, not authenticity.

Every final API card must distinguish

`value`, `ComputationResult[value]`, `Certificate`, `ConditionalResult[value]`.

Every example has the record $\mathcal{E} = (I, H, A, O, C, F, R)$: input, hypotheses, algorithm, output, certificate, deliberate failure, and reproducibility metadata.

Source modules covered here are all modules under `komorebi_math.nonlinear` and `komorebi_math.dynamics`. Package control cards must also cover each namespace's `FEATURE_KEY` and `status()`.

---

37. Derivative providers and automatic differentiation

37.1 Provider protocol

For every provider $\mathfrak{D}_F$, document (d_X, d_Y, e_F, n_F), where e_F is exactness and n_F is the provider name.

$$\mathfrak{D}_F.\,\text{value}(x) = F(x), \qquad \mathfrak{D}_F.\,\text{derivative}(r, x, V) = D^r F(x)[V].$$

Public protocol symbols: `DirectionalDerivative`, `DerivativeProvider`.

Universal guards:

- $x, v_j \in \mathbb{K}^{d_X}$ and output in $\mathbb{K}^{d_Y}$.
- r is a positive supported integer and exactly r directions are supplied.
- A finite probe never establishes global derivative correctness.

37.2 Declared callable derivatives

Public symbol: `CallableDerivativeProvider`.

$$\mathcal{D} = \{r \mapsto \mathcal{D}_r\}, \qquad \mathcal{D}_r(x; v_1, \dots, v_r) \overset{\text{declared}}{=} D^r F(x)[v_1, \dots, v_r].$$

Finite symmetry probe:

$$\rho_{\text{sym}} = \max_{r, \sigma \in S_r} \|\mathcal{D}_r(x; v_{\sigma(1)}, \dots, v_{\sigma(r)}) - \mathcal{D}_r(x; v_1, \dots, v_r)\|.$$

Optional Taylor probe:

$$T_R(x; h) = F(x) + \sum_{r \in R} \mathcal{D}_r(x; h, \dots, h)/r!, \qquad \rho_T = \|F(x + h) - T_R(x; h)\|.$$

- `[CERT]` Validity is gated only by the selected finite permutation-symmetry residuals. - `[DIAG]` The Taylor residual is recorded when requested but does not change `certificate.valid`. - `[UNCHECKED]` Global validity and the omitted Taylor remainder. - `[FAIL]` Missing order, asymmetric declaration, bad dimensions.

37.3 Polynomial tensors

Public symbol: `PolynomialDerivativeProvider`.

Factorial convention:

$$F(x) = \sum_{m=0}^{M} \frac{1}{m!} T_m[x^m], \qquad T_m \in Y \otimes (X^*)^{\otimes m}.$$

Directional derivative:

$$D^r F(x)[v_1, \dots, v_r] = \sum_{m=r}^{M} \frac{1}{(m-r)!} T_m[v_1, \dots, v_r, x^{m-r}].$$

Symmetry residual:

$$\rho_m = \max_{1 \le j < m} \|T_m - \text{swap}_{j,j+1} T_m\|.$$

- `symmetry_certificate()` passes when exact object tensors have $\rho_m = 0$, or numerical tensors have $\rho_m \le \varepsilon$. Construction validates shapes but does not itself require symmetry. - `[FAIL]` Tensor rank not $m + 1$, unequal source axes, inconsistent target dimension.

37.4 Recursive central differences

Public symbol: `FiniteDifferenceDerivativeProvider`.

$$\eta(v) = h/\max(1, \|v\|), \qquad \Delta_v F(x) = \frac{F(x+\eta v) - F(x-\eta v)}{2\eta}.$$

$$\Delta_{v_1,\dots,v_r} F = \Delta_{v_r}(\Delta_{v_1,\dots,v_{r-1}} F).$$

- **N**: error depends on h, smoothness, scale, roundoff, and order. - `[FAIL]` Nonpositive step, nonfinite output, order above `max_order`. - `[EX]` Compare $h = 10^{-2}, \dots, 10^{-8}$ with an exact polynomial oracle.

37.5 SymPy derivatives

Public symbol: `SympyDerivativeProvider`.

$$\nabla_{v_r} \cdots \nabla_{v_1} F = \sum_{i_1,\dots,i_r} v_{1,i_1} \cdots v_{r,i_r} \frac{\partial^r F}{\partial z_{i_r} \cdots \partial z_{i_1}}.$$

- **E** when expressions, substitutions, and directions remain exact SymPy objects. - `[FAIL]` Empty expressions/variables, repeated variables, bad dimensions.

37.6 Automatic differentiation

Public symbols: `DirectionalJVP`, `AutomaticDifferentiationProvider`, `JaxDerivativeProvider`, `TorchDerivativeProvider`, `autodiff_provider`, `automatic_derivative_provider`, `available_ad_frameworks`, `available_autodiff_backends`, `ad_framework_diagnostics`.

JVP primitive:

$$\mathrm{jvp}(G, x, v) = (G(x), DG(x)[v]).$$

Nested construction:

$$G_0 = F, \qquad G_j(x) = DG_{j-1}(x)[v_j], \qquad G_r(x) = D^r F(x)[v_1, \dots, v_r].$$

Availability states must remain distinct:

$$\text{installed} \Rightarrow \text{?importable} \Rightarrow \text{?JVP-capable} \Rightarrow \text{?function traceable}.$$

- JAX and PyTorch load lazily. Probes run in isolated child interpreters. - No silent numerical replacement after an AD failure. - `[FAIL]` NumPy escape, mutation, unsupported traced control flow, bad device/dtype.

37.7 Comparison example

Use

$$F(x_1, x_2) = (x_1^3 + x_1 x_2,\ x_2^2)$$

through all providers and tabulate $\rho_r^{p,q} = \|D_p^r F(x)[V] - D_q^r F(x)[V]\|$ for $r = 1, 2, 3$. Use an asymmetric wrong second derivative to force an invalid symmetry certificate, and a symmetric wrong derivative to exhibit a large non-gating Taylor diagnostic. Include an optional-backend unavailable record.

---

38. Packet jets and Faà di Bruno composition

38.1 Jet addresses and blocks

Public symbols: `PacketLabel`, `PacketJetAddress`, `PacketJet`, `PacketJetFamily`.

$$\mathcal{A}_r = B \times A^r, \qquad |\mathcal{A}_r| = |B||A|^r, \qquad \alpha = (b; a_1, \dots, a_r).$$

$$J^{(r)}_{b;a_1,\dots,a_r}(x)[v_1, \dots, v_r] = Q_b D^r F(x)[P_{a_1} v_1, \dots, P_{a_r} v_r].$$

Norm bound:

$$\|J^{(r)}_{b;\mathbf{a}}\| \le \|Q_b\| \, \|D^r F(x)\| \prod_{j=1}^{r} \|P_{a_j}\|.$$

Paired permutation symmetry:

$$J_{b;a_{\sigma(1)},\dots,a_{\sigma(r)}}[v_{\sigma(1)}, \dots, v_{\sigma(r)}] = J_{b;a_1,\dots,a_r}[v_1, \dots, v_r].$$

38.2 Reconstruction theorem

$$D^r F(x)[V] = \sum_{b \in B} \sum_{\mathbf{a} \in A^r} J^{(r)}_{b;\mathbf{a}}(x)[V].$$

$$\rho_{\mathrm{rec}} = \left\| D^r F(x)[V] - \sum_{\alpha \in \mathcal{A}_r} J_\alpha(x)[V] \right\|.$$

- `[HYP]` Complete source and target packets and a multilinear derivative. - `[FAIL]` Provider dimensions disagree or packet backends differ.

38.3 Support discovery

Public symbols: `PacketJetSupport`, `packet_jet_support`.

For packet-range bases $\mathcal{B}_a$, classify a block by exhaustive tests

$$J_\alpha[e_1, \dots, e_r] = 0 \quad \forall (e_1, \dots, e_r) \in \mathcal{B}_{a_1} \times \cdots \times \mathcal{B}_{a_r}.$$

$$\mathcal{A}_r = \mathcal{A}_r^{\neq 0} \sqcup \mathcal{A}_r^{0} \sqcup \mathcal{A}_r^{?}.$$

- Exact exhaustive scan: **E**. Tolerance scan: **N**. - Exhausted `max_evaluations`: preserve explicit `untested` addresses and mark **C**. - Untested addresses never justify pruning.

38.4 Packet Taylor polynomial

Public symbols: `PacketTaylorResult`, `packet_taylor`.

$$T_n F(x; h) = F(x) + \sum_{r=1}^{n} \frac{1}{r!} \sum_{\alpha \in \mathcal{A}_r} J_\alpha(x)[h^r].$$

$$\rho_n(x, h) = \|F(x + h) - T_n F(x; h)\|.$$

- `[CERT]` Reconstruction of every retained derivative order. - `[DIAG]` `certificate.valid` does not depend on the observed truncation residual. - `[UNCHECKED]` No automatic omitted-remainder bound.

38.5 Faà di Bruno formula

Public symbols: `Partition`, `set_partitions`, `stirling_second`, `labeled_composition_term_count`, `FaaDiBrunoTerm`, `FaaDiBrunoResult`, `faa_di_bruno`, `packet_faa_di_bruno`, `ComposedDerivativeProvider`.

For $H = F \circ G$,

$$D^n H(x)[V] = \sum_{\pi \in \Pi_n} D^{|\pi|} F(G(x)) \left[D^{|B|} G(x)[v_i]_{i \in B} \right]_{B \in \pi}.$$

Counts:

$$|\Pi_n| = \sum_{k=0}^{n} S(n,k), \qquad N_{\text{labeled}}(n,m) = \sum_{k=1}^{n} S(n,k) m^k.$$

Packet decoration for output c, inputs a_i, and intermediate label map $\lambda : \pi \to M$:

$$Q_c D^n (F \circ G)(x)[P_{a_1} v_1, \dots, P_{a_n} v_n]$$

$$= \sum_{\pi \in \Pi_n} \sum_{\lambda : \pi \to M} J^F_{c;(\lambda(B))_{B \in \pi}} \left[J^G_{\lambda(B);(a_i)_{i \in B}} [v_i]_{i \in B} \right]_{B \in \pi}.$$

Pruning rules:

- Prune when the outer jet has certified-zero support.
- Prune when any required inner jet has certified-zero support.
- Incomplete support cannot prove a zero.
- Reject a raw term count above `max_terms` before support pruning. Support cannot rescue an already over-budget raw count.
- Without `direct_provider`, a valid classical Faà di Bruno certificate records finite partition assembly, not an independent derivative comparison.

38.6 Sparse symmetric tensors

Public symbols: `SparseTensorEntry`, `SparseSymmetricTensor`, `SparsePolynomialDerivativeProvider`.

Store one coefficient per nondecreasing orbit $i_1 \le \cdots \le i_r$. Contract via distinct permutations:

$$T[v_1, \dots, v_r]_o = \sum_{(o,\mathbf{i},c)} c \sum_{\sigma \in \mathrm{Orb}(\mathbf{i})} \prod_{j=1}^{r} (v_j)_{i_{\sigma(j)}}.$$

$$N_{\text{dense}} = d_Y d_X^r, \qquad \rho_{\text{storage}} = N_{\text{stored}} / N_{\text{dense}}.$$

- `[CERT]` Sparse/dense contraction and provider parity. - `[FAIL]` Decreasing orbit, duplicate orbit, asymmetric dense source.

38.7 Finite snapshots

Public symbols: `PacketJetCoefficient`, `PacketJetSnapshot`, `snapshot_packet_jet`.

$$c_{o;i_1,\dots,i_r} = (J[e_{i_1}, \dots, e_{i_r}])_o,$$

$$J[v_1, \dots, v_r]_o = \sum_{i_1,\dots,i_r} c_{o;i_1,\dots,i_r} \prod_{j=1}^{r} (v_j)_{i_j}.$$

- Exact zero omission is **E**. Tolerance omission is **N** and records the largest omitted norm. - Digest identity is **I**, not authorship.

38.8 Example ladder

- Reproduce `nonlinear_jets_composition.py`. Print order-one through order-four partitions.
- Force partial support and retain `untested` blocks.
- Compare exact dense/sparse `Fraction` tensors.
- Snapshot, portable roundtrip, digest, and tamper rejection.

---

39. Nonlinear trees and graded operations

39.1 Ordered rooted trees

Public symbols: `MultilinearOperation`, `OrderedRootedTree`, `ordered_tree_count`, `ordered_rooted_trees`, `ordered_trees_with_leaves`, `catalan_number`.

$$\tau ::= \bullet \mid B_r(\tau_1, \dots, \tau_r), \qquad r \in \mathcal{R} \subset \{2, 3, \dots\}.$$

Record $h(\tau), L(\tau), I(\tau), V(\tau)$, arity profile, prefix form, and serialization.

$$N_0 = 1, \qquad N_h = 1 + \sum_{r \in \mathcal{R}} N_{h-1}^r,$$

$$C_n = \frac{1}{n+1}\binom{2n}{n}.$$

- `[FAIL]` Arity below two, negative height, or family above `max_trees`.

39.2 Fixed-point tree expansion

Public symbols: `TreeTerm`, `TreeExpansionResult`, `PolynomialFixedPointProblem`.

$$u = s + \sum_{r \in \mathcal{R}} B_r(u^r) =: \Phi(u), \qquad u_0 = 0, \quad u_{m+1} = \Phi(u_m).$$

$$\operatorname{val}(\bullet) = s, \quad \operatorname{val}(B_r(\tau_1, \dots, \tau_r)) = B_r(\operatorname{val}\tau_1, \dots, \operatorname{val}\tau_r).$$

Finite identity:

$$u_m = \sum_{h(\tau) < m} \operatorname{val}(\tau).$$

- `[CERT]` Tree sum equals matching Picard iterate. - `[UNCHECKED]` Convergence as $m \to \infty$.

39.3 Majorant convergence

Public symbols: `MajorantConvergence`, `majorant_convergence`, `quadratic_catalan_majorant`.

Assume $\|B_r(x_1, \dots, x_r)\| \le b_r \prod_j \|x_j\|$, define

$$\phi(t) = a + \sum_r b_r t^r, \qquad a \ge \|s\|.$$

Certificate conditions and tail:

$$\phi(R) \le R, \qquad q = \sum_r r b_r R^{r-1} < 1, \qquad \|u - u_m\| \le \frac{q^m a}{1-q}.$$

Quadratic small root:

$$4ab < 1, \qquad R = \frac{1 - \sqrt{1 - 4ab}}{2b}.$$

- **C**: operation bounds and completeness are caller hypotheses. - `[FAIL]` $4ab \ge 1$, $\phi(R) > R$, or $q \ge 1$.

39.4 Packet-labeled trees

Public symbols: `PacketTreeResult`, `packet_tree_reconstruction`.

Insert $I = \sum_a P_a$ on every edge:

$$\mathrm{val}(\tau) = \sum_{\text{packet labelings } \ell} \mathrm{val}(\tau, \ell).$$

- Only certified-zero jet blocks prune labelings. - Record evaluated/pruned counts and direct reconstruction residual.

39.5 Finite abelian gradings

Public symbols: `FiniteAbelianGroup`, `GradingCertificate`, `GradedPacketOperation`, `GradedConvolutionTerm`, `GradedConvolutionResult`. Module-visible callable aliases: `GradedOperationCallable`, `LinearOperation`, `BracketOperation`.

$$X = \bigoplus_{g \in \Lambda} X_g, \qquad \ell_r(X_{g_1}, \dots, X_{g_r}) \subseteq X_{g_1 + \cdots + g_r}.$$

$$(\ell_r \star x)_g = \sum_{g_1 + \cdots + g_r = g} \ell_r(x_{g_1}, \dots, x_{g_r}).$$

39.6 Maurer-Cartan packets

Public symbols: `MaurerCartanResult`, `maurer_cartan_packets`, `HigherMaurerCartanResult`, `higher_maurer_cartan_packets`, `DividedSquareResult`, `divided_square_packets`.

$$\mathrm{MC}(\eta) = d\eta + \tfrac{1}{2}[\eta, \eta], \qquad \mathrm{MC}_g = d\eta_g + \tfrac{1}{2} \sum_{a+b=g} [\eta_a, \eta_b].$$

$$\mathrm{MC}^{(R)}(\eta) = \sum_{r=1}^{R} \ell_r(\eta^r)/r!.$$

Characteristic-sensitive alternative:

$$d\eta + q(\eta), \qquad q(x+y) = q(x) + q(y) + [x, y].$$

- `[CERT]` Finite packet reconstruction. - `[UNCHECKED]` Declared multilinearity, grading, and any infinite tail. - `[EX]` Reproduce `nonlinear_trees_elimination.py`. Add Catalan counts, majorant failure, packet pruning, cyclic grading, and characteristic two.

---

40. Defects, obstruction, lifting, and holonomy

40.1 Nonlinear coordinates and refinement defect

Public symbols: `NonlinearPacketMap`, `NonlinearRefinementDefect`.

Packet conjugation:

$$\widehat{F} = A_Y \circ F \circ S_X.$$

`NonlinearPacketMap.fixed_point_residual()` certifies that the residual was computed. `certificate.valid=True` does not assert that the residual vanishes or that the input is fixed.

Refinement defect:

$$\delta_{C_X, C_Y}(F)(x) = C_Y F_f(x) - F_c(C_X x).$$

For the implemented orbit and fixed-point bounds, declare endomaps and a common coarsening $C_X = C_Y =: C$, and abbreviate $\delta_C := \delta_{C,C}$.

If F_c is L-Lipschitz and $\varepsilon_j = \|\delta_C(F)(F_f^j(x))\|$,

$$\|CF_f^n(x) - F_c^n(Cx)\| \le \sum_{j=0}^{n-1} L^{n-1-j}\varepsilon_j.$$

If x_f is fine-fixed and F_c contracts by $q < 1$,

$$\|Cx_f - x_c\| \le \|\delta_C(F)(x_f)\|/(1-q).$$

- **C**: Lipschitz/contraction constants are declared. - `[FAIL]` $q \ge 1$ or supplied fine point is not fixed.

40.2 Linear obstruction

Public symbols: `ObstructionResult`, `LinearObstructionProblem`, `ObstructionSquare`.

$$Du = -\delta, \qquad \mathrm{ob}(\delta) = \pi_{\mathrm{coker}\, D}(\delta).$$

$$\mathrm{ob}(\delta) = 0 \iff \delta \in \mathrm{im}\, D, \qquad u = u_0 + \ker D.$$

For a commuting correction square,

$$C_Y D_X = D_Y C_X, \qquad [\delta] \mapsto [C_Y \delta], \qquad \rho_\square = \|C_Y D_X - D_Y C_X\|.$$

- Exact quotient arithmetic where supported. Numerical rank/residual otherwise. - `require_correction()` rejects a nonzero obstruction.

40.3 Exact linear lifting

Public symbols: `ModularLinearSolution`, `solve_mod_prime`, `LiftStepResult`, `LinearLiftProblem`.

$$Au = b \pmod p, \qquad u = u_0 + \sum_{j=1}^{\nu} c_j k_j, \qquad N_{\mathrm{sol}} = p^\nu.$$

For $Ax_k = b \pmod{p^k}$, let

$$x_{k+1} = x_k + p^k u, \qquad r_k = (Ax_k - b)/p^k \pmod p, \qquad Au = -r_k \pmod p.$$

40.4 Polynomial lifting and finite trees

Public symbols: `PolynomialLiftProblem`, `LiftTreeNode`, `FiniteLiftTree`, `build_lift_tree`.

$$F(x_k + p^k u) \equiv F(x_k) + p^k J_F(x_k) u \pmod{p^{k+1}},$$

$$J_F(x_k) u = -F(x_k)/p^k \pmod p.$$

- Exhaustively validate the Jacobian law over all p^{d_X} residual corrections: **E**. - Above `linearization_limit`, require explicit trust and mark **C**. - Verify every child directly modulo p^{k+1}. - `max_nodes` and enumeration limits bound branch explosion. - A finite nonempty tree does not prove an infinite p-adic branch.

40.5 Finite graph holonomy

Public symbols: `TransportEdge`, `FundamentalHolonomy`, `IntertwiningResult`, `TransportGraph`.

For edge $e : v \to w$, let $T_e : X_v \to X_w$ be invertible. Choose root r and tree transports $S_v : X_r \to X_v$. For each non-tree edge,

$$H_e = S_w^{-1} T_e S_v.$$

Gluing criterion and gauge action:

$$H_e = I \ \forall e \notin T, \qquad T_e \mapsto G_w T_e G_v^{-1}, \qquad \beta_1 = |E| - |V| + 1.$$

For two systems and root intertwiner R,

$$R_v = S_v' R S_v^{-1}, \qquad R_w T_e = T_e' R_v, \qquad R H_e = H_e' R.$$

40.6 Example ladder

- Reproduce `obstruction_lifting.py`: solvable, obstructed, unique, branching, and terminating cases.
- Force the conditional trusted-Jacobian path.
- Reproduce `holonomy.py`. Show gauge invariance and a broken cycle.

---

41. Correction and elimination

41.1 Hilbert obstruction projector

Public symbols: `HilbertObstructionResult`, `HilbertObstructionProjector`.

For SVD-resolved $D : X \to Y$,

$$\Pi_{\text{im}} = U_r U_r^*, \qquad \Pi_{\text{coker}} = I - \Pi_{\text{im}}, \qquad o = \Pi_{\text{coker}}\delta.$$

$$\|o\| = \operatorname{dist}(-\delta, \operatorname{im} D), \qquad u_* = -D^+\delta \quad (\|o\| \le \varepsilon).$$

- `[CERT]` Orthogonal decomposition, distance identity, least-norm correction residual. - `certificate.valid` can be true while `vanishes=False`. Solvability is represented by `vanishes`, not certificate validity alone. - `[UNCHECKED]` Rank stability below the singular-value threshold.

41.2 Right-inverse correction

Public symbols: `RightInverseCorrectionResult`, `RightInverseCorrectionProblem`.

Solve $Dx + N(x) = y$ by

$$\Phi(x) = R(y - N(x)), \qquad x_{m+1} = \Phi(x_m), \qquad x_0 = 0.$$

Hypotheses:

$$DR = I, \qquad q = \|R\| L_N < 1, \qquad \|R(y - N(0))\| \le (1 - q) R_0.$$

Stability:

$$\|x(y) - x(\tilde{y})\| \le \frac{\|R\|}{1 - q} \|y - \tilde{y}\|.$$

- **C**: declared Lipschitz bound throughout the ball. - `[FAIL]` $q \ge 1$, failed ball invariance, iterate exits ball, iteration cap.

41.3 Lyapunov-Schmidt reduction

Public symbols: `LyapunovSchmidtDecomposition`, `LyapunovSchmidtPoint`, `LyapunovSchmidtReduction`.

At $F(x_0) = 0$, $L = DF(x_0)$, resolve

$$X = \ker L \oplus X_1, \qquad Y = \operatorname{im} L \oplus C.$$

For $x = x_0 + K\kappa + X_1\xi$, solve

$$\Pi_{\text{im}} F(x_0 + K\kappa + X_1\xi) = 0$$

for $\xi = \psi(\kappa)$, then

$$\kappa_{\text{red}}(\kappa) = \Pi_C F(x_0 + K\kappa + X_1\psi(\kappa)).$$

$$D\psi(0) = 0, \qquad D\kappa_{\text{red}}(0) = 0.$$

- SVD resolves spaces. Damped Newton solves the range equation. - **C**: local rank constancy and branch uniqueness. - `[FAIL]` Base is not a root or range Jacobian becomes singular.

41.4 Nonlinear Schur elimination

Public symbols: `SchurDerivativeResult`, `SchurSecondDerivativeResult`, `HiddenSolveResult`, `NonlinearSchurElimination`.

Split $F = (F_P, F_Q)$ on retained u and hidden v. Assume

$$F_Q(u_0, v_0) = 0, \qquad D_v F_Q(u_0, v_0) \text{ invertible.}$$

$$Dv = -(D_v F_Q)^{-1} D_u F_Q, \qquad F_{\mathrm{red}}(u) = F_P(u, v(u)).$$

$$DF_{\mathrm{red}} = D_u F_P + D_v F_P Dv.$$

For directions h, k,

$$D^2 v[h,k] = -(D_v F_Q)^{-1} D^2 F_Q[(h, Dv[h]), (k, Dv[k])],$$

$$D^2 F_{\mathrm{red}}[h,k] = D^2 F_P[(h, Dv[h]), (k, Dv[k])] + D_v F_P D^2 v[h,k].$$

- `[CERT]` Hidden residual and first/second implicit derivatives. - **C**: local invertibility and convergence. - `[EX]` Extend `nonlinear_trees_elimination.py` with contraction failures and finite-difference derivative checks.

---

42. Filtered lifting and finite spectral sequences

42.1 Finite decreasing filtration

Public symbol: `FilteredVectorSpace`.

$$V = F^0 V \supseteq F^1 V \supseteq \cdots \supseteq F^N V = 0, \qquad \mathrm{gr}^k V = F^k V / F^{k+1} V.$$

For coordinate weights $w_i \geq 0$,

$$F^k V = \mathrm{span}\{e_i : w_i \geq k\}.$$

Document $\dim F^k V$, $\dim \mathrm{gr}^k V$, graded coordinates, lifts, and certificate.

- **E**: RREF, subspaces, quotients, and coordinates over $\mathbf{F}_p$.
- `[FAIL]` Nonprime modulus, noncontiguous/nonnested levels, nonzero terminal level.

42.2 One-depth correction

Public symbols: `DepthObstructionResult`, `FilteredCorrectionProblem`.

For filtration-preserving $D : V \to W$ and $\delta \in F^k W$, solve

$$\mathrm{gr}^k D([u]) = -[\delta], \qquad \delta + Du \in F^{k+1} W.$$

- `[CERT]` Preservation at $k, k+1$, graded equation, and every lifted child. - `[FAIL]` Defect at wrong depth or nonpreserving map.

42.3 Finite compatible branches

Public symbols: `FiniteFilteredBranchResult`, `verify_finite_filtered_branch`.

$$F(x_k) \in F^k W, \qquad x_{k+1} - x_k \in F^k V.$$

If terminal depth N is reached, $F^N W = 0$ forces $F(x_N) = 0$.

- Prefix ending before N: continuation remains unchecked.
- Terminal branch with nonzero defect fails.

42.4 Conditional inverse limit

Public symbols: `ProjectiveLimitRecord`, `conditional_projective_limit_completion`.

Require external declarations

$$\bigcap_k F^k V = 0, \qquad V \cong \varprojlim V/F^k V, \qquad F \text{ continuous}, \qquad (x_k)_k \text{ compatible and infinite.}$$

Only then conditionally conclude

$$x = \lim_k x_k, \qquad F(x) = 0.$$

- **C**: runtime records but does not establish infinite/topological assumptions. - Never promote a finite prefix to infinite existence.

42.5 Filtered cochain complex

Public symbols: `SpectralSequenceEntry`, `SpectralSequencePage`, `FilteredSpectralSequenceResult`, `FiniteFilteredCochainComplex`.

$$\cdots \xrightarrow{d^{n-1}} C^n \xrightarrow{d^n} C^{n+1} \to \cdots, \qquad d^{n+1}d^n = 0, \qquad d(F^pC^n) \subseteq F^pC^{n+1}.$$

$$Z_r^{p,n} = \{x \in F^pC^n : dx \in F^{p+r}C^{n+1}\}, \qquad B_r^{p,n} = F^pC^n \cap d(F^{p-r}C^{n-1}).$$

$$E_0^{p,q} = F^pC^{p+q}/F^{p+1}C^{p+q}.$$

For $r \geq 1$, use the implemented finite subquotient

$$E_r^{p,q} = Z_r^{p,p+q}/(Z_{r-1}^{p+1,p+q} + B_{r-1}^{p,p+q}).$$

$$d_r : E_r^{p,q} \to E_r^{p+r,q-r+1}.$$

Page relation:

$$\dim E_{r+1}^{p,q} = \dim E_r^{p,q} - \operatorname{rank} d_r^{p,q} - \operatorname{rank} d_r^{p-r,q+r-1}.$$

Finite terminal convergence:

$$\sum_{p+q=n} \dim E_\infty^{p,q} = \dim H^n(C), \qquad \operatorname{rank} d_\infty = 0.$$

- **E** over $\mathbf{F}_p$. - `[FAIL]` $d^2 \neq 0$, inconsistent dimensions, or failed filtration preservation. - `[EX]` Extend `filtered_transport.py` with a failed depth obstruction and inverse-limit truth table.

---

43. Nonlinear execution, streaming, profiling, and GPU paths

43.1 Projection-cached plan

Public symbols: `PacketJetInputGroup`, `PacketJetExecutionPlan`, `compile_packet_jet_plan`, `PacketJetEvaluation`, `PacketJetBatchResult`, `execute_packet_jet_plan`, `execute_packet_jets`.

$$N_{\text{addr}} = |B||A|^r.$$

Group active addresses by ordered input tuple $\mathbf{a} = (a_1, \dots, a_r)$, evaluate once

$$w_{\mathbf{a}} = D^r F(x)[P_{a_1} v_1, \dots, P_{a_r} v_r],$$

and reuse $J_{b;\mathbf{a}} = Q_b w_{\mathbf{a}}$. Hence

$$N_{\text{calls}} = |\{\mathbf{a} : \exists b \ (b; \mathbf{a}) \text{ active}\}|.$$

Conservative pruning:

$$\mathcal{A}_{\text{pruned}} \subseteq \mathcal{A}_r^0$$

only for certified zeros.

- `[CERT]` Reconstructed batch equals direct derivative.
- `plan.matches(family)` compares only derivative order plus source and target packet names.
- `[FAIL]` Order/name mismatch or address count above `max_addresses`.
- `[UNCHECKED]` Provider identity, base point, projector matrices, tolerances, and the support proof behind pruned addresses are not plan fingerprints.

43.2 Complexity records

Public symbols: `PacketJetComplexityEstimate`, `estimate_packet_jet_complexity`.

Record

$$(N_{\text{full}}, N_{\text{active}}, N_{\text{pruned}}, N_{\text{groups}}, N_{\text{calls}}^{\text{planned}}, N_{\text{calls}}^{\text{naive}}, d_X^r).$$

- Counts are **E** for a finite plan, not asymptotic speed guarantees.

43.3 Snapshot boundary

$$\text{live provider} \xrightarrow{\text{basis capture}} \text{sparse coefficient record}, \qquad N_{\text{basis}} = d_X^r, \quad N_{\text{scalars}} = d_Y d_X^r.$$

- Snapshot stores coefficients, not executable provider semantics. - `[FAIL]` Capture above `max_evaluations` or dense conversion above `max_elements`. - `[CERT]` Snapshot/live parity on selected probes.

43.4 Resumable stream

Public symbols: `PACKET_JET_STREAM_SCHEMA`, `PACKET_JET_STREAM_SCHEMA_VERSION`, `PACKET_JET_CHUNK_SCHEMA`, `PACKET_JET_CHUNK_SCHEMA_VERSION`, `StreamState`, `CaptureMode`, `PacketJetStreamChunkRecord`, `PacketJetStreamManifest`, `PacketJetStreamWriteResult`, `PacketJetStreamSelection`, `StreamedPacketJetEvaluation`, `capture_packet_jet_stream`, `save_packet_jet_snapshot_stream`, `PacketJetSnapshotStreamReader`, `open_packet_jet_snapshot_stream`, `load_packet_jet_snapshot_stream`. Module-visible layout constants: `STREAM_MANIFEST_NAME`, `STREAM_CHUNK_DIRECTORY`, `STREAM_PARTIAL_SUFFIX`.

State machine:

$$\text{absent} \to \texttt{destination.partial} \to \text{verified staging} \to \texttt{destination}.$$

Manifest/chunk records:

$$M = (\text{metadata}, \text{progress}, (h_j)_j, \text{capture certificate}, h_M),$$

$$C_j = (\text{schema}, \text{version}, \text{payload}, \text{SHA256}(\text{payload})).$$

Direct resume matches

$$(\alpha, d_X, d_Y, n_F, e_F, x, \varepsilon, \text{chunk size}).$$

- A live callable has no portable semantic hash. Direct resume assumes unchanged behavior. - Snapshot resume also matches a complete coefficient fingerprint. - Iterators retain at most one decoded chunk at a time. - A selected range $[a, b)$ is $J_{[a,b)}[V] = \sum_{k=a}^{b-1} c_k m_k(V)$, a partial sum unless full. - `[FAIL]` Incomplete-as-complete, corrupt chunk, prefix mismatch, selection/materialization guard.

Integrity boundary:

$$\text{SHA256 consistency} \not\Rightarrow \text{signature, authorship, or trusted provenance.}$$

43.5 Profiling

Public symbols: `RuntimeProfileSample`, `RuntimeStageProfile`, `PacketJetProfileReport`, `profile_operation`, `profile_packet_jet_runtime`, `packet_jet_benchmark_contract`.

`T` is a module-level typing `TypeVar`, not a package-namespace runtime operation.

For each named stage record timings (t_i), minimum, median, maximum, Python allocation peaks, warmups, repetitions, scope, and synchronization policy.

- Timings and allocations are **H** and environment-dependent.
- `tracemalloc` does not measure total process/device memory.
- A benchmark contract does not itself execute or certify speedup.

43.6 Optional CuPy provider execution

Public symbols: `nonlinear_cupy_available`, `CupyDeviceDerivativeProvider`, `CupyPolynomialDerivativeProvider`, `CupyPacketJetExecutor`, plus aliases `CuPyDeviceDerivativeProvider`, `CuPyPolynomialDerivativeProvider`, `CuPyPacketJetExecutor`.

$$\text{host directions} \xrightarrow{\text{optional transfer}} \text{device derivative/projections} \xrightarrow{\text{optional return}} \text{host result}.$$

- `nonlinear_cupy_available()` checks only whether Python can discover a `cupy` module. It does not establish import, runtime, or device availability. - No implicit CPU fallback for a class promising CuPy execution. - Hardware certificate records the actual device/runtime boundary. - `[FAIL]` Installed package but unusable CUDA runtime. Host/device flag mismatch.

43.7 Optional CuPy snapshot execution

Public symbols: `CuPyRuntimeStatus`, `CuPyValidationResult`, `cupy_runtime_status`, `CuPySnapshotExecutor`, `CuPyPacketJetSnapshotExecutor`, `validate_cupy_snapshot`.

$$s_{\mathrm{GPU}} = (\text{installed}, \text{runtime available}, N_{\text{devices}}, \text{runtime version}, \text{error}).$$

$$\rho_{\mathrm{GPU}} = \max_j \|J_{\mathrm{GPU}}[V_j] - J_{\mathrm{CPU}}[V_j]\|.$$

- **O/N**: sampled parity only. - CPU-only systems emit unavailable/skip, never a false hardware pass.

43.8 Example ladder

- Reproduce `scalable_nonlinear.py` and `scalable_nonlinear_runtime.py`. Compare naive/planned calls, reject an order/name mismatch, and demonstrate that same-name semantic staleness is not fingerprinted by `matches`.
- Reproduce `portable_nonlinear_state.py` and `resumable_packet_jet_stream.py`.
- Interrupt, resume, select a partial range, corrupt a chunk, and test the guards.
- Emit CPU/CuPy parity or an explicit no-runtime record.

---

44. Smooth packet transport

44.1 Moving orthogonal packets

Public symbols: `PacketDerivativeResult`, `MovingPacketSystem`.

$$P_a^* = P_a, \qquad P_a^2 = P_a, \qquad P_a P_b = 0 \ (a \neq b), \qquad \sum_a P_a = I.$$

Differentiated identities:

$$\dot{P}_a = \dot{P}_a P_a + P_a \dot{P}_a, \qquad \sum_a \dot{P}_a = 0.$$

Derivative residuals:

$$\rho_{\mathrm{FD}} = \max_a \left\| \dot{P}_a(t) - \frac{P_a(t+h) - P_a(t-h)}{2h} \right\|,$$

$$\rho_{\tan} = \max_a \|\dot{P}_a - \dot{P}_a P_a - P_a \dot{P}_a\|, \qquad \rho_{\mathrm{sum}} = \|\sum_a \dot{P}_a\|.$$

- **N**: sampled evidence, not global differentiability.

44.2 Direct polar rotation

Public symbols: `DirectRotationResult`, `direct_packet_rotation`.

$$S = \sum_a Q_a P_a, \qquad U = S(S^*S)^{-1/2}, \qquad Q_a U = U P_a.$$

Record $\sigma_{\min}(S)$, $\|U^*U - I\|$, and $\max_a \|Q_a U - U P_a\|$.

- `[FAIL]` Singular or unresolved overlap sum.

44.3 Kato generator and transport

Public symbols: `KatoTransport`, `TransportRefinementResult`.

For a complete orthogonal family,

$$K(t) = \sum_a \dot{P}_a P_a = \frac{1}{2} \sum_a [\dot{P}_a, P_a], \qquad K^* = -K, \qquad \dot{P}_a = [K, P_a].$$

$$\dot{U}(t) = K(t)U(t), \qquad U(t_0) = I.$$

Midpoint step:

$$U_{j+1} = \exp(\Delta K(t_j + \Delta/2))U_j.$$

Endpoint checks:

$$\rho_U = \|U_N^* U_N - I\|, \qquad \rho_{\text{int}} = \max_a \|P_a(t_1)U_N - U_N P_a(t_0)\|.$$

Direct-rotation product on $t_0 < \cdots < t_N$:

$$U_{\text{rot}} = U(P_{N-1}, P_N) \cdots U(P_0, P_1).$$

Mesh comparison for refinement factor $q \geq 2$:

$$\rho_{\text{mesh}} = \|U_{qN} - U_N\|.$$

- **N**: a posteriori two-mesh agreement. Asymptotic convergence remains unchecked. - `[EX]` Extend `filtered_transport.py` and `kato_feshbach.py` with mesh sweep, direct rotations, and singular-overlap failure.

---

45. Matrix dynamics, Markov systems, and Bayesian flow

45.1 Matrix and packet semigroups

Public symbols: `matrix_exponential`, `MatrixSemigroup`, `PacketSemigroup`. Implementation appendix symbols: `as_square_matrix`, `hermitian_fractional_power`, `block_partition`. State their validation role and SciPy-or-Taylor exponential boundary. The semigroup identities below are exact finite mathematics. Matrix exponentials, resolvents, and certificates are **N** at runtime.

$$T(t) = e^{tA}, \qquad T(s+t) = T(s)T(t), \qquad R(z; A) = (zI - A)^{-1}.$$

$$T_{ba}(t) = Q_b T(t) P_a, \qquad T_{ca}(s+t) = \sum_b T_{cb}(s) T_{ba}(t).$$

Transfer-graph paths give minimum generator-block transfer order.

45.2 Semigroup refinement

Public symbols: `SemigroupRefinement`, `FiniteSemigroupTower`, `ProjectiveSemigroupTower`, `semigroup_refinement_defect`.

$$E = CA_f - A_cC, \qquad \Delta(t) = Ce^{tA_f} - e^{tA_c}C.$$

$$\Delta(t) = \int_0^t e^{(t-s)A_c} E e^{sA_f}\, ds.$$

$$\|\Delta(t)\| \le te^{t\max(\|A_f\|,\|A_c\|)}\|E\|.$$

$$CR_f(z) - R_c(z)C = R_c(z)ER_f(z).$$

- Duhamel uses Gauss-Legendre quadrature and checks against the direct defect. - `[FAIL]` Negative time or parameter outside a resolvent set.

45.3 Markov convention and lumping

Public symbols: `MarkovKind`, `normalize_partition`, `AggregationMap`, `aggregation_matrix`, `FiniteMarkovChain`, `ContinuousTimeMarkovChain`, `coordinate_lumpability_residual`, `MarkovLumping`.

Column conventions:

$$Q_{ij} \ge 0\ (i \ne j), \quad \mathbf{1}^T Q = 0; \qquad P_{ij} \ge 0, \quad \mathbf{1}^T P = \mathbf{1}^T.$$

$$p(t) = e^{tQ}p_0, \qquad p_n = P^n p_0.$$

Let C aggregate a partition, S be its uniform section, and N_C be the implemented basis matrix for $\ker C$. Kernel obstruction and approximate coarse operator:

$$\mathcal{O} = CAN_C, \qquad \widetilde{A}_c = CAS.$$

Exact lumpability requires $CA = A_cC$ and equal coarse rates within each source block.

$$\Delta(t) = Ce^{tA} - e^{t\widetilde{A}_c}C,$$

$$\|\Delta(t)\| \le te^{t\max(\|A\|,\|\widetilde{A}_c\|)}\|CA - \widetilde{A}_cC\|.$$

- Exact coarse construction rejects a nonlumpable partition. - Structural lumpability is exact mathematics. Source certificates and stationary/evolution calculations are **N** tolerance-based computations. - `[FAIL]` Invalid column sums, negative entries, noninteger discrete step.

45.4 Conditional expectations and martingales

Public symbols: `ConditionalExpectation`, `partition_refines`, `blocks_from_labels`, `MartingaleTower`, `ConditionalExpectationTower`.

$$(E_{\mathcal{P}} f)_i = \frac{\sum_{j\in B(i)} w_j f_j}{\sum_{j\in B(i)} w_j}, \qquad \langle f, g\rangle_w = \sum_i w_i \overline{f}_i g_i.$$

For nested partitions,

$$E_iE_j = E_{\min(i,j)}, \qquad d_0 = E_0 f, \qquad d_j = E_j f - E_{j-1} f.$$

$$\|E_m f\|_w^2 = \sum_{j=0}^{m} \|d_j\|_w^2.$$

- `[FAIL]` Nonpositive weights or nonnested partitions. - Runtime projector, tower, and energy certificates are **N** even though the finite identities are exact.

45.5 Bayesian update and sufficiency

Public symbols: `BayesianUpdate`, `BayesianPartition`, `coarsest_sufficient_partition`, `approximate_likelihood_partitio n`.

$$Z = L^T p, \qquad p'_i = L_i p_i / Z.$$

$$\|p'_L - p'_{\widetilde{L}}\|_1 \le \frac{2\sum_i p_i |L_i - \widetilde{L}_i|}{\max(Z_L, Z_{\widetilde{L}})}.$$

For block B, use the source's zero-mass convention:

$$\bar{p}_B = \sum_{i \in B} p_i, \qquad L_B^{\text{eff}} = \begin{cases} \dfrac{\sum_{i \in B} L_i p_i}{\bar{p}_B}, & \bar{p}_B > 0, \\ 0, & \bar{p}_B = 0. \end{cases}$$

$$\text{agg}(p') = \text{Bayes}(\text{agg}(p), L^{\text{eff}}).$$

Fixed sufficiency requires $L_i = L_j$ within every block for every supplied likelihood.

- `coarsest_sufficient_partition` requires exact profile equality and rejects positive tolerance.
- `approximate_likelihood_partition` uses tolerance-graph components and is **H**, not exact sufficiency.
- Normalization and posterior/coarse-posterior certificates are **N**.
- `[FAIL]` Zero evidence.

45.6 Relative entropy

Public symbols: `relative_entropy`, `relative_entropy_decomposition`.

$$D(p\|q) = \sum_{i : p_i > 0} p_i \log(p_i / q_i).$$

$$D(p\|q) = D(\bar{p}\|\bar{q}) + \sum_B \bar{p}_B D(p(\cdot \mid B)\|q(\cdot \mid B)).$$

Preserve $+\infty$ when $p_i > 0, q_i = 0$.

45.7 Bayesian flow and HMM filtering

Public symbols: `BayesianFlow`, `HiddenMarkovFilter`.

$$p_i(t) = \frac{p_i(0) e^{t s_i}}{\sum_j p_j(0) e^{t s_j}}, \qquad \dot{p}_i = p_i(s_i - \mathbb{E}_p s).$$

$$\frac{d}{dt} \mathbb{E}_{p(t)} s = \text{Var}_{p(t)}\, s.$$

$$\hat{p} = Pp, \qquad p^+ = \text{Bayes}(\hat{p}, L).$$

Exact coarse HMM filtering requires both exact transition lumpability and block-constant likelihood. Otherwise return the directly aggregated fine value with a conditional failed certificate.

45.8 Fractional dynamics

Public symbols: `fractional_power`, `fractional_semigroup`, `fractional_naturality_certificate`, `FractionalDefectResult`, `fractional_defect`.

For Hermitian $A = U\,\text{diag}(\lambda_i) U^* \succeq 0$,

$$A^\alpha = U\,\text{diag}(\lambda_i^\alpha) U^*, \qquad e^{-tA^\alpha} = U\,\text{diag}(e^{-t\lambda_i^\alpha}) U^*.$$

$$CA_f = A_c C \Longrightarrow CA_f^\alpha = A_c^\alpha C.$$

For $0 < \alpha < 1$ and common gap $\gamma > 0$,

$$\|CA_f^\alpha - A_c^\alpha C\| \le \alpha \gamma^{\alpha - 1} \|CA_f - A_c C\|.$$

- The finite spectral identities are exact theorems. Eigendecomposition and residual/bound certificates are **N**. - `[FAIL]` Non-Hermitian, negative spectrum, nonpositive exponent, or missing positive gap.

45.9 Dirichlet Green operator

Public symbol: `DirichletGreen1D`.

$$h = (N+1)^{-1}, \qquad A_h = h^{-2}\,\mathrm{tridiag}(-1,2,-1), \qquad G_h = A_h^{-1}.$$

$$G(x,y) = \min(x,y)(1-\max(x,y)), \qquad G_h = h\,[G(x_i,x_j)]_{i,j}.$$

Compare inverse identity, sampled continuum kernel, discrete eigenvalues, and implemented $O(h^2)$ mode bound. The uniform-grid formula is exact. The floating inverse certificate is **N**.

45.10 Finite Feynman-Kac

Public symbols: `FeynmanKacKind`, `FiniteFeynmanKac`.

$$L_V = Q^T - \mathrm{diag}(V), \qquad K_V(t) = e^{tL_V}.$$

Discrete step:

$$K_V = \mathrm{diag}(e^{-V})P^T.$$

$$\|K_V(t) - K_{\widetilde{V}}(t)\| \le te^{t(\|Q^T\|+\max(\|V\|_\infty,\|\widetilde{V}\|_\infty))}\|V-\widetilde{V}\|_\infty.$$

Exact coarsening requires a lumpable Markov operator and block-constant V. Propagation and perturbation certificates are **N**. A failed coarse model is returned with conditional exactness **C**.

45.11 Example ladder

- Extend `markov_bayes.py` with nonlumpable perturbation, martingale energy, exact/approximate likelihood partitions, KL chain, replicator flow, and HMM.
- Extend `fractional_survival.py` with naturality, defect bounds, and invalid PSD/gap cases.
- Add Green grid convergence and continuous/discrete Feynman-Kac coarsening pass/fail.

---

46. Feshbach reduction, memory, and survival

46.1 Block decomposition and resolvent

Public symbol: `FeshbachReduction`.

$$A = \begin{bmatrix} A_{PP} & A_{PQ} \\ A_{QP} & A_{QQ} \end{bmatrix}.$$

At least one retained and one hidden coordinate are required. `retained_to_hidden` is the historical name for top-right A_{PQ}. `hidden_to_retained` is A_{QP}.

Using the code convention $(zI-A)^{-1}$,

$$\Sigma(z) = A_{PQ}(zI_Q - A_{QQ})^{-1}A_{QP}, \qquad A_{\mathrm{eff}}(z) = A_{PP} + \Sigma(z).$$

$$P(zI-A)^{-1}P = (zI_P - A_{\mathrm{eff}}(z))^{-1}.$$

$$\rho_{\mathrm{Fesh}} = \|(zI_P - A_{\mathrm{eff}})^{-1} - P(zI-A)^{-1}P\|.$$

- `[HYP]` Full and hidden resolvents exist.
- The Schur identity is exact finite algebra. The source certificate is **N**.
- `[FAIL]` Singular hidden or full resolvent.

46.2 Hidden-state memory

Eliminate y from

$$\dot{x} = A_{PP}x + A_{PQ}y, \qquad \dot{y} = A_{QP}x + A_{QQ}y.$$

$$\dot{x}(t) = A_{PP}x(t) + A_{PQ}e^{tA_{QQ}}y(0) + \int_0^t K(t-s)x(s)\,ds,$$

$$K(t) = A_{PQ}e^{tA_{QQ}}A_{QP}, \qquad f_Q(t) = A_{PQ}e^{tA_{QQ}}y(0).$$

46.3 Rational memory realization

Public symbols: `MemoryKernel`, `RationalMemoryKernel`, `RationalMemoryRealization`.

$$K(t) = Be^{tD}C, \qquad \widehat{K}(z) = B(zI - D)^{-1}C.$$

$$\widehat{K}_T(z) = B(zI - D)^{-1}(I - e^{(D-zI)T})C.$$

$$\widehat{K}(z) - \widehat{K}_T(z) = B(zI - D)^{-1}e^{(D-zI)T}C.$$

`MemoryKernel.certificate(..., points=...)` records the requested point count but performs no quadrature and does not use `points` to determine its value or validity.

Auxiliary system:

$$\frac{d}{dt}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix}.$$

Its retained component realizes the Volterra memory equation.

46.4 Finite local closure

Cayley-Hamilton reduces closure to

$$M_j = A_{PQ}A_{QQ}^j A_{QP}, \qquad j = 0, \dots, d_Q - 1.$$

$$M_j = 0\ \forall j < d_Q \iff \text{hidden feedback closes locally;}$$

otherwise it produces memory. The equivalence is exact. `local_closure_certificate` is **N** and accepts when $\max_j \|M_j\|_2 \le \varepsilon$.

46.5 Kernel and trajectory bounds

Public symbols: `kernel_l1_error`, `memory_kernel_error_bound`, `volterra_trajectory_bound`.

$$\delta_K = \int_0^T \|K_1(t) - K_2(t)\|\,dt.$$

Rational kernels combine exponential norm bounds with sampled quadrature plus derivative allowance. Arbitrary callables receive only a conditional trapezoidal estimate.

$$\|x_1 - x_2\|_{[0,T]} \le MT\delta_K \exp((a+\kappa)T).$$

- **C**: M, a, κ are declared trajectory/local/kernel bounds.
- `[FAIL]` Negative/nonfinite data or missing declared bounds.

46.6 Phase-type survival

Public symbol: `PhaseTypeSurvival`.

For stable transient column subgenerator Q, the constructor normalizes its supplied initial vector. Write $p_0 = p_{\text{supplied}}/(\mathbf{1}^T p_{\text{supplied}})$. Then

$$p(t) = e^{tQ}p_0, \qquad S(t) = \mathbf{1}^T p(t), \qquad a = -\mathbf{1}^T Q.$$
$$f(t) = a\,p(t), \qquad h(t) = f(t)/S(t).$$

Model conditions:

$$Q_{ij} \geq 0\ (i \neq j), \qquad a_j = -\sum_i Q_{ij} \geq 0, \qquad \max \operatorname{Re}\sigma(Q) < 0.$$

For cause rates $a^{(c)}$, require $\sum_c a_j^{(c)} = a_j$.

Transform and moments:

$$\mathbb{E}[e^{-sT}] = a(sI - Q)^{-1}p_0,$$
$$\mathbb{E}[T^m] = m!\,\mathbf{1}^T(-Q)^{-m}p_0.$$
$$f_c(t) = a^{(c)}p(t), \qquad \sum_c f_c(t) = f(t), \qquad p_t^{\text{res}} = p(t)/S(t).$$

Identity certificate checks $-S'(t) = f(t)$ by centered difference and the cause sum.

- Model admissibility, transforms, moments, and identity checks are **N**. Stability is required below `-tolerance`, and the centered-difference identity certificate uses a fixed 10^{-5} threshold.
- `[FAIL]` Unstable generator, negative rate, inconsistent causes, or restart at zero survival.

46.7 Example ladder

- Extend `feshbach_memory.py` with safe resolvent sweep, local-closure/nonclosure pair, rational realization, and finite-horizon bounds.
- Extend `kato_feshbach.py` with explicit sign-convention comparison.
- Extend `fractional_survival.py` with competing risks, residual lifetime, transform/moment checks, and invalid models.
- Do not identify a generic memory kernel with survival unless Markov subgenerator hypotheses are independently certified.

VII.A Cross-chapter case studies

VII.A.1 Nonlinear coarse-model pipeline

$$\text{provider} \to \text{packet jets} \to \text{support} \to \text{plan} \to \text{snapshot/stream} \to \delta_C(F) \to \text{obstruction/correction}.$$

Record

$$(\rho_{\text{derivative}}, \rho_{\text{packet}}, N_{\text{active}}, h_{\text{stream}}, \|\delta_C(F)\|, \text{ob}(\delta), \rho_{\text{corrected}}).$$

VII.A.2 Finite-to-infinite boundary

Keep separate

$$F(x_k) = 0 \pmod{p^k} \quad \forall k \leq N \quad \text{(E)},$$

from

$$\exists x \in \varprojlim X/p^k X :\ F(x) = 0 \quad \text{(C; external infinite hypotheses)}.$$

VII.A.3 Dynamic memory pipeline

$$e^{tA} \to \text{packet blocks} \to \text{coarse defect} \to \text{Feshbach split} \to K(t) \to \text{rational realization}.$$

Do not let a small finite residual become an unqualified infinite-dimensional claim.

VII.B Certificate and failure schema

Every final table must include: object, claim class, residual formula, tolerance, checked hypotheses, unchecked hypotheses, failure behavior, and theorem identifier.

Failure families:

- Shape: dimension, tensor rank, packet count, retained/hidden block mismatch.
- Algebra: nonprime modulus, singular Jacobian/resolvent, noncommuting square, nontrivial holonomy, $d^2 \neq 0$.
- Hypothesis: failed contraction, filtration, lumpability, sufficiency, positivity, gap, or survival stability.
- Resource: `max_terms`, `max_trees`, `max_evaluations`, `max_nodes`, dense/stream materialization guards.
- Optional backend: not installed, import/JVP failure, no CUDA runtime/device, CPU/GPU mismatch.
- Integrity: payload/chunk digest mismatch, incomplete stream, tampered portable envelope, digest without authentication.

VII.C Source example crosswalk

Guide locus	Existing executable seed	Symbolic extension
37 through 38	`nonlinear_jets_composition.py`	All providers, orders 1 through 4, partial support, failure probes
38, 43	`scalable_nonlinear.py`	Exact sparse parity, plan counts, snapshot integrity
43	`scalable_nonlinear_runtime.py`	Stage profiles, order/name mismatch, same-name staleness caveat, optional GPU parity
38, 43	`portable_nonlinear_state.py`	Dense guard, multiple probes, tamper taxonomy
43	`resumable_packet_jet_stream.py`	Interrupted resume, partial range, corrupt chunk
39, 41	`nonlinear_trees_elimination.py`	Majorant failure, second derivatives, Newton failures
40	`obstruction_lifting.py`	Solvable/obstructed cases and all lift branch types
40	`holonomy.py`	Intertwiners, exact backend, nontrivial cycle
42, 44	`filtered_transport.py`	Depth obstruction, inverse-limit flags, mesh sweep
44, 46	`kato_feshbach.py`	Rotation product, refinement, resolvent relation
45	`markov_bayes.py`	Nonlumpable case, KL, HMM, martingale tower
45 through 46	`fractional_survival.py`	Defect bound, competing risks, invalid models
46	`feshbach_memory.py`	Closure pair, realization, callable comparison

VII.D Documentation requirements

- Every public class receives a constructor card.
- Every public method/property receives a symbolic contract.
- Compatibility aliases point to canonical symbols.
- Sign, packet, and Markov column conventions are explicit.
- Conditional conclusions list unchecked assumptions.
- Optional backends have deterministic unavailable paths.
- Integrity statements distinguish digest from signature.
- Combinatorial routines expose resource guards.
- Every chapter contains an invalid-certificate case and an exception case.
- Examples print expected values, residuals, and metadata.
- Theorem identifiers are reconciled with the final source manifest.
- PDF rendering preserves matrices, long symbols, links, and cross-references.

87. Integration, expressions, quantum, deformation, and Langlands

Source clarifications for the Part VIII specifications. The reader chapters supply four implementation details: `Exact Polynomial.evaluate` is exact only at exact coordinates. `max_terms` is enforced while sparse expansions grow rather than wholly before expansion. The displayed `ErrorGuarantee` chain is a conceptual evidence hierarchy, not Python enum ordering, and the integration-coordinate FTC uses a square degree-`n` derivative operator, while the tight degree-lowering derivative belongs to the Chapter 51 expression primitive.

Specifications for integration, expressions, quantum, deformation, and Langlands models

These specifications supplement Chapters 47 through 58. Every displayed relation retains its intended evidence class:

- **E**: finite exact arithmetic under checked hypotheses.
- **N**: finite numerical computation with a stated residual and tolerance.
- **C**: conditional result retaining named unchecked hypotheses.
- **H**: heuristic or estimated diagnostic.
- **P**: planned exposition or reserved extension, not a shipped theorem.

The final guide must not remove these tags until the accompanying certificate, hypotheses, and failure behavior have been written beside the formula.

Shared symbolic grammar for Chapters 47 through 58

Typed objects

Use this object-level notation consistently:

$$\begin{aligned}
\mathsf{Poly}_d(\mathbb{Q}) &= \{p : \mathbb{Q}^d \to \mathbb{Q} \text{ with finite support}\},\\
\mathsf{Meas}_d^{+} &= \{\text{implemented finite positive measures of dimension } d\},\\
\mathsf{Quad}_d &= \{\text{finite signed quadrature functionals of dimension } d\},\\
\mathsf{P}_n^B &= \operatorname{span}_{\mathbb{Q}}\{b_0, \dots, b_n\},\\
\mathsf{Lin}(X, Y) &= \operatorname{Hom}_{\mathbb{Q}}(X, Y),\\
\mathsf{M}_d(\mathbb{C}) &= \text{finite complex } d \times d \text{ matrices},\\
\mathsf{F}_p^n &= \text{finite } n\text{-dimensional vector space over } \mathbb{F}_p.
\end{aligned}$$

Certificate record used in the prose

For an operation $F : X \to Y$, display its evidence as

$$\mathrm{Cert}(F, x) = (\tau, \mathrm{id}, H_{\checkmark}, H_{?}, r, \varepsilon, D),$$

where:

- $\tau \in \{\mathrm{E}, \mathrm{N}, \mathrm{C}, \mathrm{H}, \mathrm{P}\}$.
- id is the theorem or operation identifier.
- $H_{\checkmark}$ is the finite list of replayed hypotheses.
- $H_{?}$ is the list of assumptions not established internally.
- r is an exact discrepancy or numerical residual.
- ε is the comparison tolerance when numerical.
- D is deterministic diagnostic data.

Certificate composition uses the public strongest-to-weakest order

$$\mathrm{E} \prec \mathrm{N} \prec \mathrm{C} \prec \mathrm{H} \prec \mathrm{P},$$

and, for $m \geq 1$, obeys

$$H_{?}^{\mathrm{out}} = \bigcup_{i=1}^{m} H_{?}(C_i),$$

$$S_H = \begin{cases} \{\mathrm{C}\}, & H_{?}^{\mathrm{out}} \neq \emptyset, \\ \emptyset, & H_{?}^{\mathrm{out}} = \emptyset, \end{cases} \qquad \tau_{\mathrm{out}} = \max_{\prec}(\{\tau(C_i) : 1 \leq i \leq m\} \cup S_H)\,.$$

The empty composition has status **E**. Thus newly introduced unchecked assumptions impose a conditional floor even when every child is exact. No downstream operation may silently strengthen a child certificate.

Standard symbolic example frame

Every worked example in these chapters should be outlined as

$$\mathcal{E} = (I, H, A, O, C, F, R),$$

with input I, hypotheses H, algorithm A, output O, certificate C, deliberate failure F, and related symbols R.

Part VIII. Exact finite integration and typed expressions

47. Measures and exact polynomials

47.0 Scope boundary

Implemented scope:

$$\text{finite sparse rational polynomials} \quad + \quad \text{explicit finite-dimensional measures.}$$

Excluded from the chapter's claims:

$$\text{general Lebesgue theory}, \quad \text{improper integrals}, \quad \text{distributions},$$
$$\text{infinite product measures}, \quad \text{stochastic integration}.$$

47.1 `ExactPolynomial` as a typed sparse object

Define

$$p(x) = \sum_{\alpha \in S} c_\alpha x^\alpha, \qquad S \subset \mathbb{N}^d \text{ finite}, \qquad c_\alpha \in \mathbb{Q}.$$

Type its public constructors as

$$\begin{aligned} \text{zero}_d &: 1 \to \mathsf{Poly}_d(\mathbb{Q}), \\ \text{constant}_d &: \mathbb{Q} \to \mathsf{Poly}_d(\mathbb{Q}), \\ \text{monomial}_d &: \mathbb{Q} \times \mathbb{N}^d \to \mathsf{Poly}_d(\mathbb{Q}), \\ \text{univariate} &: \mathbb{Q}^{n+1} \to \mathsf{Poly}_1(\mathbb{Q}). \end{aligned}$$

The public monomial argument order is `(coefficient, exponents)`. Record the invariants

$$\dim p = d, \qquad \operatorname{supp}(p) = \{\alpha : c_\alpha \neq 0\}, \qquad \deg p = \max_{\alpha \in \operatorname{supp}(p)} |\alpha|.$$

Public inspection slots:

- `degree` and componentwise `degrees`.
- `term_count`.
- `coefficient(exponent)`.
- Exact `evaluate(point)`.
- `to_univariate_coefficients()`.
- `certificate()` and `to_dict()`.

47.2 Exact polynomial algebra

Type the algebra maps:

$$\begin{aligned} +, - &: \mathsf{Poly}_d \times \mathsf{Poly}_d \to \mathsf{Poly}_d, \\ \text{scale} &: \mathbb{Q} \times \mathsf{Poly}_d \to \mathsf{Poly}_d, \\ \cdot &: \mathsf{Poly}_d \times \mathsf{Poly}_d \to \mathsf{Poly}_d, \\ (\cdot)^k &: \mathsf{Poly}_d \times \mathbb{N} \to \mathsf{Poly}_d, \\ \partial_i &: \mathsf{Poly}_d \to \mathsf{Poly}_d, \\ J_i &: \mathsf{Poly}_d \to \mathsf{Poly}_d. \end{aligned}$$

Specify

$$\partial_i x^\alpha = \alpha_i x^{\alpha - e_i}, \qquad J_i x^\alpha = \frac{x^{\alpha + e_i}}{\alpha_i + 1}.$$

For `integrate_out(i,a,b,density=rho)`, reserve the exact rule

$$\int_a^b c_\alpha x^\alpha \rho \, dx_i = \rho c_\alpha \frac{b^{\alpha_i + 1} - a^{\alpha_i + 1}}{\alpha_i + 1} x^{\alpha - \alpha_i e_i}.$$

The result is a `Fraction` for a one-dimensional source and an `ExactPolynomial` of dimension $d - 1$ otherwise. The prose must show that multiplication, powers, and affine pullback enforce `max_terms` while sparse expansions grow.

47.3 Exact affine pullback

For

$$T : \mathbb{Q}^m \to \mathbb{Q}^d, \qquad T(y) = Ay + b,$$

type

$$T^* : \mathsf{Poly}_d(\mathbb{Q}) \to \mathsf{Poly}_m(\mathbb{Q}), \qquad T^*p = p \circ T.$$

Certificate schema:

$$C_{T^*p} = (\mathrm{E}, \texttt{exact-affine-pullback}, \{A, b \text{ rational}, \text{ shape valid}, \text{ budget met}\}, \emptyset, 0, 0, D).$$

Failure slots:

- incompatible source dimension.
- Negative exponent.
- Nonrational coefficient.
- Expansion beyond `max_terms`.
- Malformed point passed to `evaluate`.

47.4 Positive measure protocol

Type the protocol

$$\mu \in \mathsf{Meas}_d^+ \quad \Longrightarrow \quad \begin{cases} \mathrm{mass}(\mu) \in \mathbb{R}_{\geq 0}, \\ m_\alpha(\mu) = \int x^\alpha \, d\mu, \\ \mathrm{Cert}(\mu). \end{cases}$$

The guide must separate structural positivity from signed numerical functionals.

47.5 Atomic measures

Define

$$\mu = \sum_{j=1}^{N} w_j \delta_{x_j}, \qquad w_j \geq 0, \qquad x_j \in \mathbb{Q}^d \text{ or } \mathbb{R}^d.$$

Then

$$\mu(1) = \sum_j w_j, \qquad m_\alpha(\mu) = \sum_j w_j x_j^\alpha, \qquad \int f \, d\mu = \sum_j w_j f(x_j).$$

Method outline:

- `atom_count`.
- `mass()` and `moment(alpha)`.
- `normalized()` when mass is positive.
- `coalesced()` for equal atoms.
- `certificate()`.

Failure slots: negative weight, inconsistent point dimension, zero-mass normalization, nonfinite numerical data.

47.6 Interval, product, and pushforward measures

For an interval measure,

$$d\mu(x) = \rho \, dx\big|_{[a,b]}, \qquad \rho \geq 0, \qquad a \leq b,$$

derive

$$m_k(\mu) = \rho \frac{b^{k+1} - a^{k+1}}{k+1}.$$

Document `structurally_zero`, `normalized`, and `pushforward_affine`.

For products, let $d_j = \dim \mu_j$ and split $\alpha = (\alpha^{(1)}, \dots, \alpha^{(r)})$ with $\alpha^{(j)} \in \mathbb{N}^{d_j}$. Then

$$\mu = \bigotimes_{j=1}^{r} \mu_j, \qquad m_\alpha(\mu) = \prod_{j=1}^{r} m_{\alpha^{(j)}}(\mu_j).$$

For `ExactAffineMap`, expose

$$T(x) = Ax + b, \qquad S \circ T(x) = B(Ax + b) + c, \qquad \det T = \det A \text{ when square.}$$

For pushforward,

$$T_{\#} : \mathsf{Meas}_d^+ \to \mathsf{Meas}_m^+, \qquad \int f \, d(T_{\#}\mu) = \int f \circ T \, d\mu.$$

Distinguish exact affine maps from arbitrary callables. Only the former can support exact symbolic moment replay in general.

47.7 Symbolic example ladder

1. **E0:** $p(x) = 1 - 2x + x^4$, compute support, degree, derivative, and primitive.
2. **E1:** $\mu = \frac{1}{3}\delta_0 + \frac{2}{3}\delta_1$, compute mass and moments.
3. **E1:** $d\mu = dx$ on $[0, 1]$, derive $m_k = 1/(k + 1)$.
4. **E2:** $(dx|_{[0,1]})^{\otimes 2}$, integrate $x^2 y + 3y$.
5. **E2:** $T(x) = 2x + 1$, materialize the atomic pushforward.
6. **F:** attempt to treat weights $(1, -1)$ as an `AtomicMeasure`.

48. Integration providers and quadrature

48.0 Integration dispatcher as a typed case split

Outline `integrate(integrand, measure, provider=None)` as

$$\text{integrate} : (\mathsf{ExactPolynomial}_d \cup \mathsf{Callable}_d) \times \mathsf{Measure}_d \times (\mathsf{CompositeSimpson} \cup \{\emptyset\}) \to \mathsf{IntegralResult}.$$

The `provider` argument is keyword-only. Derivative-provider objects use the separate public function `integrate_derivative_provider(...)`. They are not an `integrand` branch of `integrate(...)`. The final prose must display which branch is exact, which is numerical, and which requires an explicit quadrature rule.

48.1 Signed quadrature functionals

Define

$$Q[f] = \sum_{i=1}^{N} w_i f(x_i), \qquad w_i \in \mathbb{Q} \text{ or } \mathbb{R}.$$

Public maps:

$$Q : f \mapsto Q[f],$$
$$Q^{(1)} \otimes Q^{(2)} : f(x, y) \mapsto \sum_{i,j} w_i^{(1)} w_j^{(2)} f(x_i, y_j),$$
$$Q[x^\alpha] : \alpha \mapsto \text{quadrature moment.}$$

Cover `node_count`, `exact_data`, `positive`, `apply`, `moment`, `integrate_polynomial`, `tensor_product`, `as_atomic_measure`, `degree_of_exactness`, `certify_polynomial_integral`, and `certificate`.

The conversion

$$Q \mapsto \sum_i w_i \delta_{x_i}$$

is allowed only when every $w_i \geq 0$.

48.2 Exactness through moments

The shipped certification methods are one-dimensional. Define degree r exactness by

$$Q[x^k] = \int x^k \, d\mu \quad (0 \le k \le r), \qquad \dim Q = \dim \mu = 1.$$

Type the result

$$\text{degree_of_exactness}(Q, \mu, R) \to \mathsf{QuadratureExactness}(r, R, e, C).$$

An exact certificate for $Q[p] = \int p \, d\mu$ requires

$$r \ge \deg p.$$

Do not infer exactness above the maximum tested degree. Multivariate tensor moments may be compared manually, but the public method does not issue a multivariate degree certificate.

48.3 `IntegralResult` and `IntegrationError`

Outline

$$\mathsf{IntegralResult} = (\text{value}, \text{certificate}, \text{error}, \text{method}, \text{evaluations}).$$

The separate `ErrorGuarantee` enum has strongest-to-weakest order

$$\texttt{exact} > \texttt{rigorous} > \texttt{conditional} > \texttt{estimated} > \texttt{unknown}.$$

This is not the `Exactness` order. Explain `valid`, `exact`, and `require()` separately.

48.4 Composite Simpson branches

For $N \ge 4$ with $N \equiv 0 \pmod 4$, $h = (b-a)/N$, write

$$S_N(f) = \frac{h}{3}\left[f(a) + f(b) + 4\sum_{j \text{ odd}} f(a+jh) + 2\sum_{j \text{ even},\ 0<j<N} f(a+jh)\right].$$

If $M_4 \ge \sup_{[a,b]} |f^{(4)}|$, then

$$|I(f) - S_N(f)| \le \frac{b-a}{180} h^4 M_4.$$

Write five principal integration/error paths:

1. exact polynomial with no explicit Simpson provider: `Exactness.EXACT / ErrorGuarantee.EXACT` moment contraction.
2. Explicit polynomial Simpson with a provenance-matched derivative bound: `Exactness.EXACT / ErrorGuarantee.RIGOROUS`, meaning exact rational arithmetic computes an approximation with a generally nonzero rigorous truncation bound.
3. Explicit polynomial Simpson without that bound: `Exactness.HEURISTIC / ErrorGuarantee.ESTIMATED` from the exact rational fine/coarse difference.
4. Callable Simpson with an assumed bound: `Exactness.CONDITIONAL / ErrorGuarantee.CONDITIONAL`.
5. Callable Simpson without a bound: `Exactness.HEURISTIC / ErrorGuarantee.ESTIMATED`, because the fine/coarse Richardson difference is always computed.

`ErrorGuarantee.UNKNOWN` belongs to a bare `QuadratureRule.apply()` or `integrate_polynomial()` without a target-integral theorem, not to a Simpson branch that omitted its fine/coarse comparison.

48.5 Derivative providers

For fixed atoms and weights, define

$$F(x) = \sum_j w_j F_j(x), \qquad D^r F(x) = \sum_j w_j D^r F_j(x).$$

Type `AtomicIntegratedDerivativeProvider` as

$$(F_j, w_j)_{j=1}^N \mapsto F, \qquad \mathsf{Provider}(d_s, d_t, r) \to \mathsf{Provider}(d_s, d_t, r).$$

Reject parameter-dependent $w_j(x)$ because

$$D \sum_j w_j(x) F_j(x) = \sum_j Dw_j(x) F_j(x) + \sum_j w_j(x) DF_j(x).$$

The unimplemented first term must not be dropped.

48.6 Symbolic example ladder

1. certify a two-node exact rule against moments through degree one.
2. Tensor two exact rules and verify bivariate moments.
3. Integrate $x^4 - 2x + 1$ exactly and by Simpson.
4. Show a matched `DerivativeBound` and an assumed one side by side.
5. Fail on any Simpson count not divisible by four, including 2, 6, and odd counts.
6. Fail `as_atomic_measure()` for a negative quadrature weight.

49. Integral identities and coordinate covectors

49.1 Fundamental theorem and integration by parts

For $p \in \mathsf{Poly}_1(\mathbb{Q})$ and $d\mu = \rho\, dx|_{[a,b]}$, define $P' = p$ and certify

$$\int_a^b p(x)\rho\, dx = \rho(P(b) - P(a)).$$

For $u, v \in \mathsf{Poly}_1(\mathbb{Q})$, certify

$$\int_a^b uv'\rho\, dx = \rho[uv]_a^b - \int_a^b u'v\rho\, dx.$$

Both are finite polynomial identities, not claims about weak derivatives or general function spaces.

49.2 Finite Fubini

For $p \in \mathsf{Poly}_d$ and $\mu = \mu_1 \otimes \cdots \otimes \mu_d$, outline

$$I_\sigma(p) = \int \cdots \int p(x_1, \ldots, x_d)\, d\mu_{\sigma(1)} \cdots d\mu_{\sigma(d)}.$$

The exact finite claim is

$$I_\sigma(p) = I_\tau(p) \quad \forall \sigma, \tau \in S_d.$$

`all_fubini_orders` must document the factorial enumeration budget and `max_dimensions=7` guard.

49.3 Pushforward and oriented change of variables

For exact affine T, certify

$$\int_Y f(y)\, d(T_{\#}\mu)(y) = \int_X f(Tx)\, d\mu(x).$$

For $T(x) = sx + t$, $s \neq 0$, distinguish:

$$T_{\#}(\rho\, dx|_{[a,b]}) = \frac{\rho}{|s|}\, dy|_{[\min T(a,b), \max T(a,b)]}$$

from the oriented substitution identity, where the sign of s remains in the directed endpoints.

49.4 Coordinate integration covectors

Let

$$B_n = (b_0, \dots, b_n), \qquad p = \sum_{k=0}^{n} c_k b_k.$$

Define

$$\ell_{B,\mu} = \left(\int b_0\, d\mu, \dots, \int b_n\, d\mu \right), \qquad \int p\, d\mu = \ell_{B,\mu} c.$$

Type

$$\ell_{B,\mu} : \mathsf{P}_n^B \to \mathbb{Q}.$$

For a basis change $C_{S\to T}$, require

$$\ell_T C_{S\to T} = \ell_S.$$

For the derivative matrix $D_n : \mathsf{P}_n \to \mathsf{P}_{n-1}$, require

$$\ell_{n-1} D_n = \rho(e_b - e_a).$$

A bare weight vector is only a finite functional until its triangular basis witness is replayed.

49.5 Analysis-synthesis commutation

For atomic samples $f = (f(x_1), \dots, f(x_N))$, weights w, analysis A, and synthesis S, outline the diagram

$$f@ > A >> c$$

$$@Vw^T VV@VVw^T SV$$

$$\mathbb{K}@ = \mathbb{K}$$

with the finite check

$$w^T f = w^T S A f.$$

The certificate must incorporate the frame-system certificate. Zero-valued samples must not allow an invalid SA to pass vacuously.

49.6 Canonical worked identity

Reserve the full derivation

$$f(y) = y^4 - 2y + 1, \qquad y = 2x + 1, \qquad x \in [0, 1],$$

so that

$$\int_0^1 f(2x+1)\, dx = \frac{106}{5}.$$

Show the same scalar via direct pullback, pushforward measure, monomial covector, and one nonmonomial coordinate family.

50. Typed finite expression model

50.0 Semantic universe

Restrict the model to

$$\mathbb{Q}, \qquad \mathsf{P}_n^B, \qquad \mathsf{Lin}(X, Y).$$

Explicitly exclude arbitrary CAS terms, higher-order functions, analytic identities, nonlinear maps, and infinite-dimensional operators.

50.1 Type witnesses

Type records:

$$\begin{aligned} \mathsf{RationalSpace} &: \dim = 1, \\ \mathsf{PolynomialCoordinateSpace}(x, n, B) &: \dim = n + 1, \\ \mathsf{LinearMapType}(X, Y) &: X \to Y. \end{aligned}$$

Semantic identity is

$$\mathrm{key}(\mathsf{P}_n^B) = (x, n, B),$$

not a mutable display label.

50.2 Expression grammar

Give the formation rules:

$$\frac{v \in X}{\mathrm{Value}(v) : X}, \qquad \frac{A \in \mathsf{Lin}(X, Y)}{\mathrm{Map}(A) : X \to Y},$$

$$\frac{A : X \to Y \quad B : Y \to Z}{B \circ A : X \to Z}, \qquad \frac{A, B : X \to Y}{A + B : X \to Y},$$

$$\frac{q : \mathbb{Q} \quad A : X \to Y}{qA : X \to Y}, \qquad \frac{A : X \to Y \quad x : X}{A(x) : Y}.$$

Cover nodes `ExactValueLiteral`, `ExactMapLiteral`, `Symbol`, `Let`, `IdentityMap`, `ZeroMap`, `Compose`, `Sum`, `Scale`, and `Apply`.

Clarify ordering:

$$\mathrm{compose}(B, A) = B \circ A, \qquad \mathrm{then}(A, B) = B \circ A.$$

50.3 Lexical binding

For

$$\text{let } x = e_1 \text{ in } e_2,$$

record

$$\mathrm{type}(e_1) = \mathrm{declared}(x), \qquad \mathrm{FV}(e_2) \setminus \{x\}.$$

Binder identity is object identity, not merely string equality. Plan paired examples for shadowing, same-name free symbols, and alpha-equivalent binders.

50.4 Budgets and structural safety

Outline `ExpressionStats` as

$$(N_{nodes}, D, N_{steps}, N_{entries}, n_{max}, b_{max}, B_{json}).$$

Outline `ExpressionBudget` inequalities

$$N_{nodes} \le N_*, \quad D \le D_*, \quad n_{max} \le n_*, \quad b_{max} \le b_*, \quad B_{json} \le B_*.$$

Cycle rejection and maximum symbol length belong in the construction chapter, not only the persistence chapter.

50.5 Failure matrix

Include one symbolic failure for each:

- vector length mismatch.
- Matrix shape mismatch.
- Composition endpoint mismatch.
- Sum type mismatch.
- Application source mismatch.
- Let declaration mismatch.
- Cyclic object graph.
- Oversized coefficient or serialized payload.

51. Expression evaluation and certification

51.1 Basis-aware primitive maps

For source basis S and target basis T, write

$$C^{(n)}_{S\to T} = B^{-1}_{T,n} B_{S,n}.$$

The primitive ledger must include:

$$\begin{aligned}
C_{S\to T} &: \mathsf{P}^S_n \to \mathsf{P}^T_n,\\
D_B &: \mathsf{P}^B_n \to \mathsf{P}^B_{n-1} \quad (n>0),\\
D_B &: \mathsf{P}^B_0 \to \mathsf{P}^B_0 \quad (n=0),\\
J_{a,B} &: \mathsf{P}^B_{n-1} \to \mathsf{P}^B_n,\\
e_{a,B} &: \mathsf{P}^B_n \to \mathbb{Q},\\
\ell_{B,[a,b],\rho} &: \mathsf{P}^B_n \to \mathbb{Q},\\
S_{s,t} &: \mathsf{P}^B_n \to \mathsf{P}^B_n,\\
\Delta_h &: \mathsf{P}^B_n \to \mathsf{P}^B_n,\\
\partial_{a,b} &: \mathsf{P}^B_n \to \mathbb{Q},\\
\iota &: \mathbb{Q} \to \mathsf{P}^B_n.
\end{aligned}$$

The finite-difference image has degree at most $n-1$, but the shipped primitive re-encodes it in the original P^B_n coordinate space. The degree-zero derivative is the zero endomorphism. Match these with `PrimitiveKind`: coordinate change, derivative, antiderivative, evaluation, interval integration, affine substitution, finite difference, boundary functional, and constant injection.

51.2 Replay identities

Reserve exact derivations of

$$\begin{gathered}
C_{T\to U}C_{S\to T} = C_{S\to U}, \qquad C_{T\to S}C_{S\to T} = I,\\
D_T C^{(n)}_{S\to T} = C^{(n-1)}_{S\to T} D_S,\\
J_{a,T} C^{(n-1)}_{S\to T} = C^{(n)}_{S\to T} J_{a,S},\\
D_B J_{a,B} = I, \qquad J_{a,B} D_B = I - u_B e_{a,B},\\
e_{a,T}C_{S\to T} = e_{a,S}, \qquad \ell_T C_{S\to T} = \ell_S,\\
\ell_{n-1} D_n = \rho(e_b - e_a).
\end{gathered}$$

`replay_matrix` must recompute the matrix from its witness. A caller-provided label or certificate text is never sufficient.

51.3 Checking, normalization, and equality

Type the checking phase

$$\text{check} : e \mapsto (\text{type}(e), \text{stats}(e), \text{FV}(e), C_e).$$

For a closed term, define

$$\text{NF}(e) \in \mathbb{Q} \cup \mathbb{Q}^n \cup \mathbb{Q}^{m\times n}.$$

Decidable equality is

$$e_1 \equiv e_2 \iff \text{type}(e_1) = \text{type}(e_2) \ \wedge \ \text{NF}(e_1) = \text{NF}(e_2).$$

This is entrywise exact rational equality. For open terms, distinguish structural equality from a universally quantified identity.

51.4 Conservative simplification

For each `RewriteStep`, display

$$(r, \text{id}, d_{before}, d_{after}, H_{side}, C_r).$$

Candidate rules to explain symbolically:

$$I \circ A \to A, \quad A \circ I \to A, \quad A + 0 \to A, \quad 1A \to A, \quad 0A \to 0,$$

only when the type witnesses and side conditions replay.

51.5 Certificate propagation adversaries

Construct three paired examples:

1. exact parent plus invalid child ⇒ invalid result.
2. Exact parent plus numerical child ⇒ no exact upgrade.
3. Exact matrices plus unchecked side condition ⇒ conditional.

52. Expression planning and persistence

52.1 Matrix-chain dynamic program

For dimensions $(p_0, \dots, p_n)$, let $A_i \in \mathbb{Q}^{p_{i-1}\times p_i}$. Define

$$m[i,i] = 0,$$

$$m[i,j] = \min_{i\le k<j} \{m[i,k] + m[k+1,j] + p_{i-1}p_k p_j\}.$$

Record split $s[i,j]$ and reconstruct a `MatrixChainTree`.

The theorem is narrow:

optimal among binary parenthesizations under dense scalar cost.

Do not claim optimization of sparsity, rank, memory, transfer, kernel launch, or numerical stability.

52.2 Expression plan IR

Outline each instruction as

$$I_k = (\text{opcode}, \text{inputs}, \text{type}, \text{payload}, c_k, C_k).$$

Then

$$P = (d_e, \text{type}(e), (I_k), k_{out}, \sum c_k, d_P, C_P).$$

`compile_expression` must emit and replay the plan. `execute_plan` must validate d_P before execution. `evaluate_expression` compares

$$\text{NF}_{direct}(e) = \text{NF}_{plan}(e).$$

52.3 Strict portable schema

Record constants:

- `EXPRESSION_SCHEMA = "komorebi_math.expression.v1".`
- `EXPRESSION_SCHEMA_VERSION = 1.`
- `EXPRESSION_NODE_VERSION = 1.`
- `EXPRESSION_TYPE_VERSION = 1.`

Canonical digest:

$$d(e) = \mathrm{SHA256}(\mathrm{CanonicalUTF8NFCJSON}(\mathrm{record}(e))).$$

The record must include the complete type witness. Rationals are reduced integer pairs, never binary floats.

52.4 Decoder threat model

Explicitly reject:

- duplicate JSON keys.
- Floats and noncanonical rational tokens.
- Unknown schema, node, or type versions.
- Digest mismatch.
- Unknown node tags.
- Excessive depth, nodes, entries, coefficient bits, or bytes.
- Cycles in reconstructed objects.
- Arbitrary class imports or function execution.

Because serialized JSON expands DAG sharing, the encoder must replay the expanded record against the same budget.

52.5 Canonical typed example

Reserve an end-to-end expression

$$e = \ell_T \, C_{S\to T} \, c_S$$

and a map identity pipeline with

$$\mathrm{NF}(e) = \frac{5}{4}, \qquad \mathrm{NF}(P) = I_4.$$

Show construction, checking, simplification, compilation, direct/plan replay, JSON roundtrip, digest equality, and one-byte tamper rejection.

Part IX. Quantum, deformation, and finite Langlands models

53. Finite quantum foundations

53.0 Scope and feature status

Domain:

finite-dimensional complex matrices and finite packet families.

Certificates are ordinarily **N**, with residual and tolerance. Exclude continuum QFT, infinite volume, Lorentzian reconstruction, anomaly cancellation, and quantum gravity conclusions.

53.1 Seed-orbit systems

For observables $A_1, \dots, A_r \in \mathsf{M}_d(\mathbb{C})$ and seeds $\psi_1, \dots, \psi_s$, define

$$\mathcal{H}_{seed} = \operatorname{span}\{A_{i_k} \cdots A_{i_1} \psi_j : k \geq 0\}.$$

`QuantumSeedSystem` exposes `dimension`, `orbit_basis`, `orbit_dimension`, `is_generating`, and `certificate`.

Rank diagnostics:

$$\operatorname{SchmidtRank}(\psi) = \operatorname{rank}(\operatorname{reshape}_{d_L \times d_R} \psi),$$

$$\text{local_orbit_dimension} = d_L \operatorname{SchmidtRank}(\psi).$$

State the singular-value threshold in every numerical rank example.

53.2 Finite symmetry projectors

For a finite representation U_g and character χ, define

$$P_\chi = \frac{d_\chi}{|G|} \sum_{g \in G} \overline{\chi(g)} U_g.$$

For $U^n = I$, define cyclic packets

$$P_q = \frac{1}{n} \sum_{r=0}^{n-1} \omega^{-qr} U^r.$$

Certificate residuals must include

$$\max_q \|P_q^2 - P_q\|, \quad \max_{q \neq r} \|P_q P_r\|, \quad \left\| \sum_q P_q - I \right\|.$$

For charge a, check

$$UAU^* = \omega^a A, \qquad P_b A P_c = 0 \text{ unless } b = c + a \pmod{n}.$$

53.3 Euclidean and spectral diagnostics

For Hermitian H, spacing $a > 0$, and reference energy E_0, define

$$T = e^{-a(H - E_0 I)}.$$

For test vectors v_i and times t_i, form

$$M_{ij} = \langle v_i, T^{t_i + t_j} v_j \rangle.$$

`reflection_certificate` checks finite positive semidefiniteness of M.

Spectral functions:

$$K(t) = \operatorname{Tr}(e^{-tL}), \qquad d_s(t) = 2t \frac{\operatorname{Tr}(L e^{-tL})}{\operatorname{Tr}(e^{-tL})}.$$

For a periodic lattice,

$$\lambda_k = \frac{4}{h^2} \sum_j \sin^2\left(\frac{\pi k_j}{N_j}\right).$$

`spectral_dimension` is a finite diagnostic, not a continuum-dimension theorem.

53.4 Constraints and anomaly residuals

Fit

$$[C_i, C_j] \approx \sum_k f_{ij}^{\ k} C_k$$

and record the quotient residual. For a coarsening map R, compute

$$\Delta_i = RC_i^{fine} - C_i^{coarse} R.$$

Call Δ_i a transported constraint defect, not proof of a continuum anomaly.

53.5 Symbolic examples and failures

1. two-qubit computational-basis generation.
2. Non-generating seed with deficient orbit rank.
3. C_n projectors and charged Pauli-style operator.
4. Periodic Laplacian and low-mode dispersion bound.
5. Nearly dependent constraints with tolerance-sensitive rank.

54. Circuits, channels, and open dynamics

54.1 Packet-expanded circuits

For gates $U_1, \dots, U_m$ and packet systems $P_a^{(j)}$, define a path block

$$B_{a_m \leftarrow a_0}^{a_1,\dots,a_{m-1}} = P_{a_m}^{(m)} U_m P_{a_{m-1}}^{(m-1)} \cdots U_1 P_{a_0}^{(0)}.$$

The reconstruction certificate checks

$$\left\| U_m \cdots U_1 - \sum_{a_0,\dots,a_m} B_a \right\| \le \varepsilon.$$

For path vectors v_γ, decompose

$$\left\| \sum_\gamma v_\gamma \right\|^2 = \sum_\gamma \|v_\gamma\|^2 + 2\,\mathrm{Re} \sum_{\gamma<\eta} \langle v_\gamma, v_\eta \rangle.$$

The constructor's path guard is

$$\prod_{j=1}^{m-1} |P^{(j)}| \le \texttt{max_paths}.$$

It bounds internal paths for one fixed source/target packet pair. The outer source and target loops used by complete reconstruction are not included.

54.2 Quantum channels

Define

$$\Phi(X) = \sum_j K_j X K_j^*, \qquad \sum_j K_j^* K_j = I \quad \text{for TP.}$$

Method map:

- `apply` and `apply_density`.
- `adjoint`.
- `is_trace_preserving` and `is_unital`.
- `superoperator` and `choi_matrix`.
- `compose` and `tensor`.
- `packet_blocks` and `covariance_certificate`.

Certificate residuals:

$$r_{TP} = \left\| \sum_j K_j^* K_j - I \right\|, \qquad r_{CP} = \max(0, -\lambda_{min}(J_\Phi)).$$

For amplitude damping,

$$K_0 = \begin{pmatrix} 1 & 0 \\ 0 & \sqrt{1-\gamma} \end{pmatrix}, \qquad K_1 = \begin{pmatrix} 0 & \sqrt{\gamma} \\ 0 & 0 \end{pmatrix}, \qquad 0 \le \gamma \le 1.$$

54.3 Lindblad generators

Define

$$\mathcal{L}(\rho) = -i[H, \rho] + \sum_j \left(L_j \rho L_j^* - \frac{1}{2}\{L_j^* L_j, \rho\} \right).$$

Expose `apply`, `superoperator`, `evolve`, `trace_preservation_certificate`, and `coherence_preservation_certificate`.

The trace certificate checks

$$\operatorname{Tr} \mathcal{L}(X) = 0$$

on the finite matrix representation. It does not establish properties of an unbounded infinite-dimensional generator.

54.4 Kato transport

For differentiable packets $P_a(t)$, define

$$K(t) = \sum_a \dot{P}_a(t) P_a(t), \qquad \dot{P}_a = [K, P_a], \qquad K^* = -K.$$

Transport solves

$$\dot{U}(t) = K(t) U(t), \qquad P_a(t) U(t) = U(t) P_a(0).$$

Document `direct_packet_rotation`, `MovingPacketSystem`, `KatoTransport`, derivative certificates, refinement certificates, and endpoint intertwining.

Finite-difference derivative checks are **N**, not proofs of differentiability.

54.5 Leakage

For fixed P, $Q = I - P$, certify

$$\|Q e^{-itH} P\| \le |t| \, \|QHP\|.$$

For moving packets, define

$$G(t) = Q(t)(H(t) - iK(t))P(t), \qquad B = \int_{t_0}^{t_1} \|G(t)\| \, dt.$$

The shipped result is **N** (`Exactness.NUMERICAL`) and carries the explicit unchecked assumption `quadrature error between samples`. It does not issue a stronger continuum error bound.

55. Error correction and effective dynamics

55.1 Quantum codes

For code projector P and errors E_a, define

$$R_{ab} = PE_a^* E_b P - \alpha_{ab} P, \qquad \alpha_{ab} = \frac{\operatorname{Tr}(PE_a^* E_b P)}{\operatorname{rank} P}.$$

Knill-Laflamme is the finite criterion

$$\max_{a,b} \|R_{ab}\| \le \varepsilon.$$

Separate three claims:

1. criterion satisfied for supplied P, E_a.
2. Recovery map constructed.
3. Chosen error mixture is trace preserving.

One does not imply the other two without their checks.

55.2 Feshbach reduction

For

$$H = \begin{pmatrix} H_{PP} & H_{PQ} \\ H_{QP} & H_{QQ} \end{pmatrix},$$

define

$$\Sigma(z) = H_{PQ}(z - H_{QQ})^{-1} H_{QP}, \qquad H_{eff}(z) = H_{PP} + \Sigma(z).$$

Reserve derivations of

$$P(z - H)^{-1} P = (z - H_{eff}(z))^{-1},$$

and, for $\operatorname{Im} z > 0$,

$$\operatorname{Im} \Sigma(z) \preceq 0.$$

The memory kernel is finite hidden-sector dynamics. Bare Markovian closure is certified only when

$$\|H_{PQ}\| \le \varepsilon.$$

55.3 Hamiltonian towers

For finite $H_0, \dots, H_N$, compute

$$\delta_n = \|H_{n+1} - H_n\|, \qquad V_N = \sum_{n=0}^{N-1} \delta_n,$$

and bound

$$\|e^{-itH_{n+1}} - e^{-itH_n}\| \le |t| \delta_n.$$

The report is finite in scope and **N**: it numerically checks the supplied adjacent norms and Duhamel bounds. Infinite-tail summability remains unchecked.

55.4 Example and failure sequence

1. exact code projector plus Pauli error set.
2. Near-miss error set with visible residual matrix.
3. Recovery-channel check independent of KL check.
4. Two-block Feshbach Hamiltonian and projected resolvent.
5. Coupled hidden sector showing nonzero memory.
6. Finite tower whose observed differences decrease but whose infinite tail is not claimed summable.

56. Finite deformation systems

56.0 Scope boundary

The implemented objects are finite lift levels, finite-field complexes, finite support computations, finite trace tables, and finite occupancy diagnostics. No finite report proves existence of an infinite deformation or inverse-limit branch.

56.1 Lift forests and visibility

For levels $X_0, \dots, X_N$ and reductions $r_m : X_m \to X_{m-1}$, define

$$\mathrm{Core}_m = X_m \cap \bigcap_{n=m+1}^{N} \mathrm{im}(r_{n\to m}).$$

`FiniteLiftForest` exposes levels, children, images, stable cores, finite branches, and report.

For rational x_i, define

$$d_{ij} = v_p(x_i - x_j) + 1,$$

and verify nesting through

$$d_{ik} \geq \min(d_{ij}, d_{jk}).$$

`VisibilityTree` exposes separation depths, partitions, refinement chains, and `ultrametric_certificate()`, which is a plain boolean exhaustive finite check rather than a `Certificate` object.

56.2 Exact chart counts

List and derive

$$N_{smooth}(q, d, m) = q^{d(m-1)},$$
$$N_{weighted}(q, w, m) = q^{\sum_i \max(m-w_i,0)},$$
$$N_{x^e=0}(q, e, m) = q^{m-\lceil m/e \rceil},$$
$$N_{xy=0}(q, m) = q^m + m(q-1)q^{m-1}.$$

For

$$R(T) = \frac{A(T)}{B(T)} = \sum_{m\geq 0} a_m T^m,$$

show how `RationalCountingSeries.coefficient` uses the exact denominator recurrence. Compare the first coefficients against direct count functions.

56.3 Finite cochain complexes

For

$$C^0 \xrightarrow{d^0} C^1 \xrightarrow{d^1} \cdots, \qquad d^{k+1}d^k = 0 \pmod{p},$$

compute

$$\dim H^k = \dim C^k - \operatorname{rank} d^k - \operatorname{rank} d^{k-1}.$$

For packetwise cohomology require

$$P_a^{k+1} d^k = d^k P_a^k, \qquad \sum_a P_a^k = I, \qquad P_a^k P_b^k = \delta_{ab} P_a^k.$$

All ranks here are exact over $\mathbb{F}_p$.

56.4 Fitting support and occupancy

For a presentation $M = \operatorname{coker} A$, define the fiber dimension

$$\dim M_x = (\#\text{generators}) - \operatorname{rank} A(x).$$

Outline `PresentedModule.fitting_generators`, `evaluate`, `fiber`, and `finite_support`. Distinguish characteristic zero from $\mathbb{F}_p$, and require denominators to remain units after reduction.

For numerical subspaces $V_1, \dots, V_r$, record

$$d_j = \dim(V_1 \cap \cdots \cap V_j), \qquad d_{j+1} \le d_j.$$

`nested_subspace_occupancy` must report principal-angle tolerance and a near-threshold failure example.

56.5 Frobenius companion systems

For a finite trace table $T = (t_{v,i})$, seek a row set S such that

$$\operatorname{rank}(t_{v,i})_{v \in S} = r.$$

Then recover multiplicities from

$$T_S m = y.$$

`finite_frobenius_separator` is exact for the supplied table, but diagnostic validity and actual separation are distinct: its certificate remains valid for a rank-deficient table, `.separating` records full column rank, and `.recover(...)` raises unless `.separating` is true. Chebotarev density or separation at unlisted places remains outside the certificate.

56.6 Deformation example ladder

1. three-level residue forest and finite complete branches.
2. Branch that terminates at the deepest supplied level.
3. p-adic visibility partition chain.
4. Direct versus rational-series chart counts.
5. Packetwise cohomology over $\mathbb{F}_p$.
6. Fitting fibers with and without optional SymPy.
7. Exact finite Frobenius multiplicity recovery.

57. Local finite Langlands packets

57.0 Status boundary

The chapter covers explicit finite fields, tame packets, Gauss sums, Heisenberg models, symplectic diagnostics, and finite bridges. These do not constitute an unrestricted local Langlands correspondence.

57.1 Explicit finite fields

Represent

$$\mathbb{F}_{p^n} = \mathbb{F}_p[t]/(f(t)), \qquad f \text{ monic irreducible of degree } n.$$

Type operations

$$+, -, \cdot : \mathbb{F}_{p^n}^2 \to \mathbb{F}_{p^n}, \qquad (\cdot)^{-1} : \mathbb{F}_{p^n}^\times \to \mathbb{F}_{p^n}^\times.$$

Define

$$\operatorname{Tr}(x) = \sum_{j=0}^{n-1} x^{p^j}, \qquad \operatorname{Nm}(x) = \prod_{j=0}^{n-1} x^{p^j}.$$

Cover encoding, decoding, coercion, enumeration, primitive generator, logarithm table, and discrete logarithm. Fail on reducible modulus, cross-field arithmetic, and inversion of zero.

57.2 Tame Frobenius orbits and packets

For $a \in \mathbb{Z}/(q^n - 1)$, define

$$\mathcal{O}(a) = \{a, qa, q^2a, \ldots\}.$$

Record orbit length, regularity, dual exponent, and self-duality. The implementation checks only that q is an integer at least two. Its interpretation as a residue cardinality is a declared hypothesis. No prime-power test is performed.

For `TameWeilPacket`, require

$$FTF^{-1} = T^q.$$

Tensor refinement uses

$$g = \gcd(n, m), \qquad \ell = \operatorname{lcm}(n, m), \qquad g\ell = nm.$$

For a special monodromy block,

$$FNF^{-1} = qN, \qquad N^\ell = 0.$$

Here `SpecialMonodromyBlock.q` accepts any positive finite float, and the relation and nilpotence certificate is **N**, not exact finite-field evidence.

57.3 Finite character sums

Define additive and multiplicative characters by

$$\psi_b(x) = \exp\left(\frac{2\pi i}{p}\operatorname{Tr}(bx)\right),$$

$$\chi_k(g^j) = \exp\left(\frac{2\pi i k j}{q-1}\right).$$

Then

$$G(\chi, \psi) = \sum_{x \in \mathbb{F}_q^\times} \chi(x)\psi(x).$$

The magnitude check is numerical even though the finite enumeration is exact at the combinatorial level.

57.4 Heisenberg models

For $x, \xi, z \in \mathbb{F}_p$, define the chosen finite cocycle and

$$\rho(x, \xi, z) = \omega^z M_\xi T_x.$$

Outline exact modular coordinate multiplication separately from the numerical complex-matrix check returned by `group_law_certificate()`. Also cover trace support on the center and the rank-one isotropic translation selector.

57.5 Symplectic and quadratic data

For an alternating matrix B, require

$$B^T = -B \pmod p, \qquad v^T B v = 0.$$

Compute rank, radical, and nondegeneracy exactly over $\mathbb{F}_p$.

At $p = 2$, a quadratic refinement satisfies

$$q(x + y) - q(x) - q(y) = B(x, y).$$

Document exhaustive enumeration limit `max_dimension=20`, and state the nondegenerate even-dimensional hypotheses for Arf and normalized Gauss sign.

57.6 Projective envelopes and bridges

Recover a form from projective commutators

$$U_i U_j U_i^{-1} U_j^{-1} \approx \omega^{B_{ij}} I.$$

Report both scalar residual and nearest prime-phase residual.

A symplectic bridge M must satisfy

$$M^T B_{target} M = B_{source} \pmod{p}, \qquad \det M \neq 0 \pmod{p}.$$

For a graph of packet bridges, certify finite cycle holonomy. Do not infer a global arithmetic correspondence from graph consistency.

58. Finite-image, ramification, and completion models

58.0 Three-layer status matrix

Keep the implementation statuses visible:

Layer	Runtime status	Mathematical status
finite image	implemented	explicit finite groups and representations
ramification	partial	finite tower diagnostics, phases may be external
global support	partial	finite Hecke/support checks only
completion gates	implemented reporter	conclusion always conditional

58.1 Finite groups and induced characters

For `FiniteGroup`, outline checks of closure, identity, inverse, and associativity. They run only when `validate=True`, and associativity is exhaustive only when `order <= associativity_limit`. Above that limit it is not checked. `FiniteGroup.certificate()` does not replay the axioms and currently returns an exact valid record even for `validate=False`. It must not be presented alone as an exhaustive group-law proof.

For $H \leq G$ and a linear character $\chi : H \to \mathbb{C}^\times$, define

$$\rho = \operatorname{Ind}_H^G \chi, \qquad \dim \rho = [G : H].$$

The induced representation certificate checks

$$\rho(g)\rho(h) = \rho(gh)$$

on the finite table within tolerance.

58.2 Orbit packets and Mackey decomposition

For a monomial action, require orbit-stabilizer

$$|\operatorname{Orb}(v)|\,|\operatorname{Stab}(v)| = |G|.$$

Dimension checks:

$$\dim \operatorname{Sym}^m V = \binom{d+m-1}{m}, \qquad \dim \bigwedge^r V = \binom{d}{r}.$$

For double cosets $H\backslash G/K$, define Mackey intersections

$$H \cap gKg^{-1}$$

and verify total induced dimension conservation.

58.3 Clifford towers and virtual boundaries

For a prime quotient $r = [G : H]$, encode steps

$$\mathrm{I} : d_G = r d_H, \qquad \mathrm{E} : d_G = d_H.$$

`CliffordTowerReport` records the I/E word, depth, and unresolved extension steps. It does not establish existence of every restriction or extension.

For a virtual character

$$\Theta = \sum_i c_i \Theta_i,$$

the symbolic L-expression is

$$L(\Theta, s) = \prod_i L(\Theta_i, s)^{c_i}.$$

Negative c_i mark a virtual boundary, not a positive automorphic realization.

58.4 Ramification towers

For an alternating quotient form B, define

$$d_{Heis} = p^{\mathrm{rank}(B)/2}.$$

The public `.heisenberg_dimension` property first requires the form rank to be even and raises otherwise. A stage must satisfy

$$\text{orbit_size} = \frac{\text{parent_order}}{\text{child_order}},$$

with strictly increasing breaks and a valid order chain.

At $p = 2$, `phase_diagnostic()` exposes Arf and Gauss-sign data only when a nondegenerate quadratic refinement was supplied. The current tower reporter has a narrower implementation check: it marks a dyadic stage as not unresolved whenever any quadratic-refinement object is present, without independently rechecking nondegeneracy. Preserve this distinction unless the reporter is repaired.

58.5 Finite Hecke and support diagnostics

For projectors e_i and commuting operators T_j, check

$$e_i^2 = e_i, \quad e_i e_k = 0 \ (i \neq k), \quad \sum_i e_i = I, \quad [e_i, T_j] = 0.$$

`SupportComparison` requires each declared source component to occur in the declared image. This is a finite support statement only.

The dyadic diagnostic records

$$X = g - 1 \in \mathbb{F}_2[C_2], \qquad X^2 = 0,$$

so rational sign projectors merge after residual reduction. Treat this as a finite algebra calculation, not a global modularity theorem.

58.6 Patching and completion gates

Define the five mandatory gates

$$G = \{R_{res}, R_{patch}, R_{comp}, R_{fiber}, R_{real}\}.$$

The conceptual exposition order is

$$R_{res} \to R_{patch} \to R_{comp} \to R_{fiber} \to R_{real}.$$

The runtime report does not enforce this dependency graph: it requires an unordered mandatory-key map and computes the conjunction of all five values. For statuses $s_g \in \{0, 1\}$, define

$$\text{complete} = \bigwedge_{g \in G} s_g, \qquad \text{unmet} = \{g : s_g = 0\}.$$

`AutomorphicCompletionReport.result()` remains a `ConditionalResult` even if all $s_g = 1$. It records that external inputs were supplied, not that the package independently proved them.

For compatible propagation, require

$$S_{common} \wedge S_{ss} \wedge S_{aut} \wedge S_{lg}.$$

No missing conjunct may be inferred from the others.

58.7 Patching plans

`AutomorphicInductionPlan` produces a sequence of formal operations from a base field, inducing field, inducing character, and optional cyclic tower.

Its shipped certificate records

$$H_? = \left\{ \begin{array}{l} \text{inducing character algebraic when required,} \\ \text{field tower satisfies external automorphic-induction hypotheses} \end{array} \right\}.$$

"Class field theory for …" is an operation string, not a separate current `assumptions_unchecked` entry. The prose may still flag it as a guide-level mathematical warning. This object is a plan, not an execution engine for those theorems.

58.8 Symbolic example ladder

1. cyclic group, subgroup, cosets, and induced character.
2. Symmetric/exterior orbit packet dimension checks.
3. Mackey packets over explicit double cosets.
4. Clifford word with one unresolved extension.
5. Ramification stage with and without dyadic phase data.
6. Finite Hecke packets and a support-losing comparison.
7. Completion report failing `REALIZATION`.
8. All five gates supplied, with result still explicitly conditional.
9. Compatible propagation with one intentionally false conjunct.

Cross-chapter symbolic capstones

A. Exact-to-conditional status preservation

Construct

$$c_S \xrightarrow{C_{S\to T}} c_T \xrightarrow{\ell_T} q \in \mathbb{Q} \xrightarrow{\text{declared input}} \mathcal{D}_{finite} \xrightarrow{G} \mathsf{ConditionalResult}.$$

Even if the first three arrows are **E**, the last output is **C** whenever $H_?(G) \neq \emptyset$.

B. Finite versus asymptotic boundary table

Finite shipped statement	Forbidden silent promotion
all supplied Fubini orders agree	general infinite product Fubini theorem
exact finite expression normal form	general theorem proving or CAS equality
finite channel Choi matrix is positive	arbitrary infinite-dimensional complete positivity
finite Hamiltonian differences are bounded	convergence of an infinite tower
finite lift branch reaches level N	existence of an inverse-limit point
supplied Frobenius rows separate constituents	Chebotarev separation theorem
finite tame packet relation holds	unrestricted local Langlands correspondence
all completion booleans were supplied true	independent proof of automorphy

C. Required certificate displays

The finished prose must print, not merely mention:

1. exact theorem identifier and empty unchecked-assumption set.
2. Numerical residual, tolerance, norm, and scale.
3. Conditional unchecked-assumption list.
4. Resource limit that bounded the finite search.
5. Deliberate invalid example and its exception or failed certificate.
6. Deterministic serialization digest where persistence is involved.

D. Source and verification anchors

Integration chapters must absorb:

- `examples/block19_measure_integration_worked_example.py`.
- Integration portion of `examples/block21_public_capability_tour.py`.
- `docs/FINITE_MEASURE_INTEGRATION.md`.
- `run_integration_verification` and `run_block19_verification`.

Expression chapters must absorb:

- `examples/block20_typed_expression_worked_example.py`.
- Expression portion of `examples/block21_public_capability_tour.py`.
- `docs/TYPED_FINITE_EXPRESSION_CALCULUS.md`.
- `run_expression_verification` and `run_block20_verification`.

Quantum chapters must absorb:

- `examples/quantum_symmetry_circuit.py`.
- `examples/quantum_channel_qec.py`.
- `examples/kato_feshbach.py`.
- `examples/euclidean_spectral.py`.
- `run_quantum_verification` and `run_block5_verification`.

Deformation and Langlands chapters must absorb:

- `examples/deformation_support.py`.
- `examples/frobenius_companions.py`.
- `examples/tame_heisenberg.py`.
- `examples/finite_image_clifford.py`.
- `examples/ramification_completion.py`.
- `run_deformation_verification`.
- All `run_langlands_*_verification` entry points.
- `run_block7_verification`.

E. Documentation requirements for these chapters

- Every public class has a typed constructor and method/property ledger.
- Every function has explicit domain, codomain, and shape constraints.
- Every exact identity states finite rational or finite-field hypotheses.
- Every numerical check states norm, tolerance, and scale.
- Every conditional result exposes all unchecked assumptions.
- Every optional SymPy path has an installation and fallback note.
- Every factorial, path, term, group-order, dimension, and sampling guard is visible.
- Every example includes a deliberate failure or adversarial variant.
- No finite diagnostic is narrated as an asymptotic or global theorem.
- No completion gate reporter is narrated as proving its external inputs.

- All code snippets are regenerated against package version `1.0.0b4`.
- All example outputs are captured from the final qualified environment.

88. Export, persistence, CLI, recipes, verification, and publication

Specifications for interfaces, verification, and publication

Scope: Chapters 59 through 81 and Appendices A through O.

Source basis:

- Komorebi Math $1.0.0b4$, archived source handoff
- reference package source, CLI parser, manifests, schemas, examples, and release scripts
- `outline_parts/interfaces.md`

These specifications state the schemas, workflow requirements, symbol contracts, example obligations, and publication checks for Parts X through XIV. They supplement the reader explanations.

Interface notation

$$\begin{aligned} \mathbb{S} &= \text{finite Unicode strings}, & \mathbb{B} &= \{\bot, \top\}, \\ \mathbb{N}_0 &= \{0, 1, 2, ...\}, & \mathbb{P} &= \text{normalized paths}, \\ \mathbb{J} &= \text{finite JSON values}, & \mathbb{H} &= \{0, \dots, 9, a, \dots, f\}^{64}, \\ \mathbb{V} &= \text{supported in-memory values}, & \mathbb{A} &= \text{finite byte strings}. \end{aligned}$$

$$\begin{aligned} \text{Exists}(p) &\iff p \text{ names a regular file}, \\ \text{Nonempty}(p) &\iff \text{size}(p) > 0, \\ \text{SafePath}(p) &\iff p \text{ is relative, normalized, and traversal-free}, \\ \text{SHA}(b) &= \text{SHA256}(b), \\ \text{Canon}(j) &= \text{canonical finite JSON encoding of } j, \\ \text{ExactBytes}(p, q) &\iff \text{bytes}(p) = \text{bytes}(q). \end{aligned}$$

Guide cross-reference identifiers use

$$\text{Anchor}(k, n) = \text{ug-}k\text{-}n.$$

Part X. Export, persistence, extension, and command-line use

59. Mathematical document model

59.0 Chapter contract

$$\mathcal{D} = \mathcal{M} \times \mathcal{B}^*,$$

where $\mathcal{M}$ is metadata and $\mathcal{B}^*$ is a finite ordered block sequence.

Required outputs:

- one type grammar for every public document block
- one constructor invariant per block
- one fluent-construction trace
- one data-to-document trace
- one invalid-document counterexample
- one renderer-neutrality statement

59.1 Metadata schema

$$M = (t, a, d, u, k)$$

with

$$t \in \mathbb{S} \setminus \{\epsilon\}, \quad a, d, u \in \mathbb{S} \cup \{\emptyset\}, \quad k \in \mathbb{S}^*.$$

Symbol	Field	Constraint
t	`title`	$\mathrm{strip}(t) \neq \epsilon$
a	`author`	optional
d	`date`	optional presentation string
u	`abstract`	optional
k	`keywords`	finite tuple

$$M_0 = (\text{Komorebi Math Export}, \emptyset, \emptyset, \emptyset, ()).$$

59.2 Block sum type

$$\mathcal{B} = \mathsf{Heading} \sqcup \mathsf{Paragraph} \sqcup \mathsf{Equation} \sqcup \mathsf{Table} \sqcup \mathsf{Code} \sqcup \mathsf{List} \sqcup \mathsf{Figure} \sqcup \mathsf{RawLatex}.$$

$$\begin{aligned}
\mathsf{Heading} &= (x, \ell, \lambda), && x \neq \epsilon,\ 1 \leq \ell \leq 6,\\
\mathsf{Paragraph} &= (x), && x \in \mathbb{S},\\
\mathsf{Equation} &= (q, \lambda, n, e), && q \neq \epsilon,\\
\mathsf{Table} &= (h, r, c, \lambda, \alpha), && |h| > 0,\ \forall row \in r:\ |row| = |h|,\\
\mathsf{Code} &= (x, g, c), && x, g \in \mathbb{S},\\
\mathsf{List} &= (x, o), && |x| > 0,\ o \in \mathbb{B},\\
\mathsf{Figure} &= (p, c, \lambda, w), && p \in \mathbb{P},\ w \neq \epsilon,\\
\mathsf{RawLatex} &= (x), && x \in \mathbb{S}.
\end{aligned}$$

$$\alpha = \emptyset \quad \vee \quad \alpha \in \{l, c, r\}^{|h|}.$$

59.3 `MathDocument` state machine

$$D_i = (M, (b_1, \dots, b_i)), \qquad D_i \xrightarrow{\text{add}(b_{i+1})} D_{i+1}.$$

$$\begin{aligned}
\text{section} &: \mathbb{S} \times \{1, \dots, 6\} \to \textsf{Heading},\\
\text{paragraph} &: \mathbb{S} \to \textsf{Paragraph},\\
\text{equation} &: \mathbb{S} \to \textsf{Equation},\\
\text{table} &: \mathbb{S}^m \times \mathbb{V}^{n\times m} \to \textsf{Table},\\
\text{code} &: \mathbb{S} \times \mathbb{S} \to \textsf{Code},\\
\text{bullet_list} &: \mathbb{S}^n \to \textsf{List},\\
\text{figure} &: \mathbb{P} \to \textsf{Figure}.
\end{aligned}$$

Mutation boundary:

- metadata and block records are frozen
- `MathDocument.blocks` is an ordered construction buffer
- rendering must not mutate D

59.4 Report-builder morphisms

$$\begin{aligned}
\text{document_from_data} &: \mathbb{V} \to \mathcal{D},\\
\text{sequence_document} &: \mathbb{V}^* \to \mathcal{D},\\
\text{certificate_document} &: \textsf{Certificate} \to \mathcal{D}.
\end{aligned}$$

Conceptual commutation:

$$v \to D(v) \to R_{\text{markdown}}(D) \quad \sim_{\text{presentation}} \quad v \to S_{\text{presentation}}(v) \to \text{tabulate}(v).$$

This is semantic presentation equivalence, not byte identity.

59.5 Document validity

$$\text{ValidDocument}(D) \iff \text{ValidMetadata}(M) \wedge \bigwedge_{b \in B} \text{ValidBlock}(b).$$

$$\text{PortableMeaning}(\textsf{RawLatex}) = \bot.$$

`RawLatex` is trusted renderer-specific material.

60. Renderers and writers

60.0 Rendering algebra

$$R_f : \mathcal{D} \times O_f \to \mathbb{S}, \quad f \in \{\text{text}, \text{markdown}, \text{html}, \text{latex}\}.$$

$$D = D' \implies R_f(D, O) = R_f(D', O).$$

Every block/renderer pair receives one explicit coverage row.

60.1 Renderer options and escaping

$$O_H = (\text{include_mathjax}, \text{title}),$$

$$O_T = (\text{document_class}, \text{class_options}, \text{packages}, \text{include_table_of_contents}, \text{number_sections}, \text{geometry}).$$

Standalone HTML structure and CSS are fixed renderer behavior, not `HtmlRenderOptions` fields.

$$\text{latex_escape} : \mathbb{S} \to \mathbb{S}, \qquad \text{latex_label} : \mathbb{S} \to \mathbb{S}.$$

Document exact option fields from source in symbol cards.

60.2 Export format universe

$$\mathcal{F} = \{\text{json}, \text{yaml}, \text{csv}, \text{tsv}, \text{text}, \text{markdown}, \text{html}, \text{latex}, \text{pdf}, \text{npy}, \text{npz}\}.$$

$$\iota : \text{Suffix} \rightharpoonup \mathcal{F}.$$

$$\text{md} \mapsto \text{markdown}, \quad \text{tex} \mapsto \text{latex}, \quad \text{txt} \mapsto \text{text}, \quad \text{yml} \mapsto \text{yaml}.$$

Undefined suffixes raise `ValidationError`.

60.3 Export option tuple

$$O_E = (t, a, d, u, w, c, p, i, z, k, h, \ell).$$

- t, a, d, u: document metadata
- w: overwrite permission
- c: create-parent permission
- p: preserve presentation type metadata
- i: JSON indentation
- z: include certificate
- k: retain generated TeX
- h: HTML options
- ℓ: LaTeX render/compiler options

$$\text{Writable}(p, O_E) \iff (\neg \text{Exists}(p) \vee w) \wedge (\text{Exists}(\text{parent}(p)) \vee c).$$

60.4 Writer morphisms

$$\begin{aligned}
\text{export_data} &: \mathbb{V} \times \mathbb{P} \times \mathcal{F} \times O_E \to \mathsf{ExportResult}, \\
\text{export_document} &: \mathcal{D} \times \mathbb{P} \times \mathcal{F} \times O_E \to \mathsf{ExportResult}, \\
\text{export_many} &: \mathbb{V} \times \mathbb{P}_{\text{directory}} \times \mathbb{S}_{\text{base}} \times \mathcal{F}^* \times O_E \to \mathsf{ExportResult}^*, \\
\text{export_bundle} &: \mathbb{V} \times \mathbb{P}_{\text{zip}} \times \mathbb{S}_{\text{base}} \times \mathcal{F}^* \times O_E \to \mathsf{ExportBundleResult}.
\end{aligned}$$

$$E = (p, f, n, C, \gamma).$$

$$\text{ValidExport}(E) \iff \gamma.\text{valid} \wedge \text{Exists}(p) \wedge \text{size}(p) = n > 0.$$

60.5 Format-specific contracts

JSON :	$v \to S_{\text{presentation}}(v)$	sorted keys, finite JSON,
YAML :	$v \to \text{safe_dump}(v)$	requires PyYAML,
CSV/TSV :	$v \to (h, r)$	rectangular table,
TEXT :	$v \to D \to R_{text}(D)$	human presentation,
MD/HTML/TEX :	$v \to D \to R_f(D)$	localized figures,
PDF :	$v \to D \to \text{TEX} \to \text{PDF}$	external compiler,
NPY :	$v \to \text{asarray}(v)$	pickle disabled,
NPZ :	$v \to \{name \mapsto array\}$	compressed, pickle-free.

60.6 Figure localization

$$a_i = \text{stem}(t) + \texttt{_asset_} + \text{pad}_3(i) + \text{suffix}(p_i).$$

$$\text{LocalizeSafe}(p_i, a_i, w) \iff \text{Exists}(p_i) \wedge (\neg\,\text{Exists}(a_i) \vee \text{ExactBytes}(p_i, a_i) \vee w).$$

60.7 LaTeX compilation state machine

$$\mathcal{L} = \{\text{auto}, \text{pdflatex}, \text{xelatex}, \text{lualatex}, \text{latexmk}\}.$$

$$\text{source.tex} \xrightarrow{\text{resolve_latex_engine}} e \xrightarrow{\text{compile_latex}} (p_{pdf}, p_{log}, r, \gamma).$$

$$\text{ValidCompilation} \iff r = 0 \wedge \text{Exists}(p_{pdf}) \wedge \text{Nonempty}(p_{pdf}) \wedge \gamma.\text{valid}.$$

Required guards:

- shell escape disabled by default
- finite positive timeout
- return code checked
- requested engine available
- auxiliary retention explicit
- compiler log retained
- `latexmk` must not re-enable shell escape

60.8 Manifested bundle

$$B = (p, M, F, p_m, \gamma).$$

$$\mathcal{M}_B = \{(m, \text{size}(m), \text{SHA}(\text{bytes}(m))) : m \in M\}.$$

$$\text{ValidBundle}(B) \iff \gamma.\text{valid} \wedge \forall m \in M : \text{SafePath}(m) \wedge \text{ManifestMatches}(B).$$

`ExportBundleResult.valid` itself is only γ.valid. The stronger predicate above is a guide/release replay requirement, not a guarantee currently established by that result certificate. The ZIP contains `MANIFEST.sha256`, while p_m names the external `<zip>.manifest` companion.

60.9 Export adversaries

- unknown suffix
- existing output without overwrite
- absent parent with creation disabled
- nonrectangular table input
- missing PyYAML
- missing LaTeX engine
- compiler timeout
- missing figure asset
- conflicting localized asset
- unsafe or colliding bundle member

61. Portable persistence

61.0 Separation of serialization layers

$$S_{\text{presentation}} : \mathbb{V} \to \mathbb{J}, \qquad S_{\text{portable}} : \mathbb{V}_{\text{registered}} \to \mathbb{J}_{\text{versioned}}.$$

$$S_{\text{presentation}} \not\equiv S_{\text{portable}}.$$

The first optimizes export. The second promises strict versioned reconstruction.

61.1 Portable value grammar

$$\begin{aligned} v ::= {} & \text{null} \mid \text{bool} \mid \text{int} \mid \text{finite float} \mid \text{string} \\ & \mid [v_1, \dots, v_n] \\ & \mid \{\text{type} : t, \text{version} : n, \text{data} : v\}. \end{aligned}$$

Built-in structural tags:

$$\begin{aligned} &\{\text{python.fraction}, \text{python.complex}, \text{python.path}, \text{python.bytes}, \text{python.tuple}, \\ &\ \text{python.set}, \text{python.frozenset}, \text{python.mapping}, \text{numpy.ndarray}\}. \end{aligned}$$

$$\text{keys}(v) = \{\text{type}, \text{version}, \text{data}\}.$$

61.2 Codec and migration schemas

$$K = (T, t, n, e, d),$$

where T is represented type, t immutable tag, n current version, $e : T \to \mathbb{V}$, and $d : \mathbb{V} \to T$.

$$\mu = (t, n, n+1, m), \qquad m : \mathbb{V}_n \to \mathbb{V}_{n+1}.$$

$$\text{UniqueTag}(t) \land \text{UniqueType}(T), \qquad \text{Adjacent}(\mu) \iff \mu.to = \mu.from + 1.$$

61.3 Canonical encoding and digest

$$E(v) = \text{to_portable_data}(v), \qquad C(v) = \text{Canon}(E(v)),$$

$$d(v) = \text{SHA}(\text{UTF8}(C(v))).$$

$$v_1 = v_2 \implies d(v_1) = d(v_2)$$

for deterministically encoded values.

61.4 Envelope schema

$$P(v) = \begin{cases} \texttt{schema}: & \texttt{komorebi-math.portable}, \\ \texttt{schema_version}: & 1, \\ \texttt{producer_version}: & \texttt{1.0.0b4}, \\ \texttt{payload_sha256}: & d(v), \\ \texttt{payload}: & E(v). \end{cases}$$

No additional or missing envelope field is accepted.

61.5 Decode relation

$$\text{loads_portable}(P) = D(\text{VerifyDigest}(P)).$$

$$\begin{aligned} \text{UTF8} &\to \text{JSON} \to \text{UniqueKeys} \to \text{ExactEnvelopeSchema} \\ &\to \text{FinitePayload} \to \text{DigestMatch} \to \text{KnownTag} \\ &\to \text{MigrationPath} \to \text{Decoder}. \end{aligned}$$

$$\text{DecodeAuthority} = \text{RegisteredCodecTable}\,.$$

No arbitrary class import or instantiation is permitted.

61.6 Resource guards

$$\delta(v) \le d_{\max}, \qquad d_{\max} = 128 \text{ by default.}$$

Reject excessive depth, duplicate keys, nonfinite numbers, invalid base64, unhashable or duplicate mapping keys, negative ndarray dimensions, shape mismatch, unknown tags, unsupported versions, missing migrations, and decoder failures.

61.7 Atomic file persistence

$$v \xrightarrow{\text{dumps_portable}} s \xrightarrow{\text{write+flush+fsync}} p_{tmp} \xrightarrow{\text{replace}} p.$$

$$\text{load_portable}(\text{save_portable}(v, p)) \cong v.$$

$$\text{FailureBeforeReplace} \implies \text{OriginalDestinationUnchanged}\,.$$

61.8 Frozen codec contract

$$K_c = (s, n, p, (k_1, \dots, k_{51}))$$

with schema `komorebi-math.portable-codec-contract`, version 1.

$$\begin{aligned} K_{old} \preceq K_{new} \iff\ & \forall k \in K_{old} : \text{tag}(k) \in K_{new} \\ & \wedge \text{type}_{new}(k) = \text{type}_{old}(k) \\ & \wedge \text{version}_{new}(k) \ge \text{version}_{old}(k) \\ & \wedge \forall i \in [n_{old}, n_{new} - 1] : (k, i, i+1) \in \mathcal{M}. \end{aligned}$$

$$|K| = 51, \qquad |\mathcal{M}| = 1.$$

`nonlinear.packet_jet_snapshot` is version 2 with migration $1 \to 2$.

61.9 Persistence example ladder

- E_0: `Fraction` roundtrip
- E_1: ndarray shape/dtype roundtrip
- E_2: registered Komorebi object
- E_3: nested heterogeneous state
- E_4: packet-jet snapshot migration
- E_A: payload tamper rejection
- E_B: unknown-tag rejection
- E_C: depth-limit rejection
- E_D: atomic overwrite policy

62. Provenance, registries, and extensions

62.1 Claim-status alphabet

$$\mathcal{Q} = \{\text{definition}, \text{proved}, \text{classical input}, \text{conditional theorem}, \text{finite certificate}, \text{heuristic}, \text{conjecture}, \text{planned}\}.$$

This is the public `ClaimStatus` alphabet, not `Exactness`. Do not impose a false total order: `ClaimStatus` identifies claim kind, not scalar confidence.

62.2 Provenance record

$$R_p = (i, t, q, s, A, L, V).$$

- i: immutable identifier
- t: title
- $q \in \mathcal{Q}$: status
- s: source
- A: assumptions
- L: limitations
- V: verification suite

$$\text{describe} : \text{Object} \rightharpoonup R_p.$$

$$\mathsf{ClaimBox} = (i, q, A, L, V, \text{ObservedEvidence}).$$

$$q = \text{finite certificate} \not\Rightarrow q = \text{proved global theorem}.$$

62.3 Feature registry

$$F = (\text{key}, \text{module}, \text{title}, \text{status}, \text{summary}, \text{papers}, \text{dependencies}, \text{public_objects}), \qquad \text{key}_i = \text{key}_j \implies i = j.$$

$$\text{status} \in \{\text{implemented}, \text{partial}, \text{experimental}, \text{planned}, \text{external theorem required}\}.$$

unless explicit replacement authority is supplied.

$$\text{register_feature}, \quad \text{feature}, \quad \text{features}.$$

62.4 Extension schema

$$X = (n, v, a, M, D, d, r).$$

- n: name
- v: extension version
- a: extension API version
- M: contributed modules
- D: optional dependencies
- d: description
- r: registration callback

$$X.\,\text{activate}() : r();\ \text{return}\ \emptyset.$$

$$\mathcal{E}_P = \text{entry_points}(\texttt{komorebi_math.extensions}).$$

$$L = (\text{entry_point}, \text{loaded}, \text{extension}, \text{error}).$$

With `discover_extensions(activate=True)`, successful activation is implicit in `loaded=True`. An activation exception is captured as `loaded=False` plus `error`.

62.5 Extension isolation

$$\begin{aligned}
\text{FailureIsolated}(L_i) &\iff \neg L_i.\mathit{loaded} \implies \forall j \neq i : \text{DiscoveryContinues}(L_j),\\
\text{CoreStableUnchanged}(X) &\iff \mathcal{S}^{\mathit{after}}_{\mathit{stable}} = \mathcal{S}^{\mathit{before}}_{\mathit{stable}},\\
\text{CodecNotImplicitlyStable}(X) &= \top.
\end{aligned}$$

Required examples:

- installable miniature distribution
- discovery without activation
- explicit activation
- failing import isolated into a diagnostic
- explicit warning for extension codec contract scope

63. Complete CLI reference

63.0 Invocation equivalence

$$\text{exec}(\texttt{komorebi}\ a) = \text{exec}(\texttt{python}\ {-}\texttt{m}\ \texttt{komorebi_math}\ a).$$

Equality means the same parser and semantics under one interpreter/environment.

63.1 Command contract schema

$$C_c = (P_c, O_c, D_c, I_c, J_c, X_c, W_c, E_c).$$

- P_c: positional grammar
- O_c: option grammar
- D_c: defaults
- I_c: input decoder
- J_c: stdout/stderr or JSON schema
- X_c: exit-code map
- W_c: filesystem writes and overwrite policy
- E_c: executable examples

$$\forall c \in \mathcal{C}_{CLI} : \exists!\ \text{Anchor}(c).$$

63.2 Exit semantics

$$\text{exit}(c) = \begin{cases} 0, & \text{RequestedPredicate}(c) = \top, \\ 1, & \text{ValidationOrRequiredCapability}(c) = \bot, \\ 2, & \text{UsageOrChoiceError}(c). \end{cases}$$

63.3 Output and write discipline

$$\text{stdout}(c) = \text{JSON}(R_c) \oplus \backslash\text{n}$$

when JSON is promised.

$$\text{MayWrite}(c, p) \iff p \in W_c \wedge (\neg\,\text{Exists}(p) \vee \text{–force}).$$

63.4 Identity, API, and verification grammar

$$\begin{aligned} \text{info} &: () \to R_{identity}, \\ \text{doctor} &: () \to R_{environment}, \\ \text{features} &: () \to F^*, \\ \text{describe OBJECT} &: \mathbb{S} \to R_p \cup \{\emptyset\}, \\ \text{api check} &: (m, s, t) \to R_{api}, \\ \text{api snapshot} &: (p, w, t) \to p, \\ \text{golden} &: () \to R_{golden}, \\ \text{verify SUITE} &: \mathcal{V}_{51} \to R_{suite}. \end{aligned}$$

$$t \in \{\text{research}, \text{beta}, \text{stable}\}.$$

63.5 Release grammar

$$\begin{aligned} \text{release contract} &: () \to R_{contract}, \\ \text{release environment} &: () \to R_{env}, \\ \text{release qualify} &: (g, r, p, w) \to R_{qual}, \\ \text{release upgrade} &: () \to R_{upgrade}, \\ \text{release evidence} &: (current, p, w) \to R_{evidence}, \\ \text{release documentation} &: () \to R_{docs}, \\ \text{release readiness} &: (final, g, r, p, w) \to R_{ready}. \end{aligned}$$

$$\text{–gpu} = \text{execute optional probes}, \qquad \text{–require-gpu} = \text{make GPU success release-blocking}.$$

63.6 Domain-command grammar

$$\begin{aligned} \text{stream inspect PATH} &: (p, a, v) \to R_{stream}, \\ \text{stream verify PATH} &: (p, a) \to R_{verify}, \\ \text{sequence NAME} &: (n, t, i, m, c) \to R_{sequence}. \end{aligned}$$

$$\mathcal{C}_{coord} = \{\text{catalog}, \text{euler}-\text{fibonacci}, \text{recurrence}, \text{basis}, \text{model}, \text{polynomial}, \text{combinatorial}, \text{spectral}, \text{packet}, \text{formal}\}.$$

$$\mathcal{C}_{gen} = \{\text{mask}, \text{cartier}, \text{kernel}, \text{bell}\}, \quad \mathcal{C}_{arith} = \{\text{standard}-\text{window}, \text{euler}\}.$$

$$\mathcal{C}_{finite} = \{\text{deformation count}, \text{langlands tame}-\text{orbit}, \text{langlands heisenberg}, \text{langlands completion}\}.$$

Each subcommand receives input shape, accepted values, decoder, output schema, and malformed input.

63.7 Export and LaTeX CLI

$$\mathcal{C}_{export} = \{\text{formats}, \text{sequence}, \text{standard}-\text{window}, \text{euler}, \text{json}, \text{bundle}\}.$$

$$O_{cli-export} = (p, f, t, a, d, u, c, m, e, n, x, k, q, w).$$

$$\begin{aligned} \text{latex engines} &: () \to \{\text{pdflatex}, \text{xelatex}, \text{lualatex}, \text{latexmk}\} \to \mathbb{B}, \\ \text{latex compile SOURCE} &: (s, p, e, n, t, k) \to R_{compile}. \end{aligned}$$

63.8 Legacy-alias warning

$$\text{komorebi verify all} = \text{historical Block 17 aggregate}.$$

$$\text{verify all} \neq \text{verify block20} \neq \text{full pytest} \neq \text{Block 21 gate}.$$

Part XI. Connected recipes

Recipe calculus

Every recipe is

$$\mathcal{E} = (I, H, A, O, C, F, R),$$

where I is input, H hypotheses, $A = (a_1, \dots, a_n)$ actions, O expected output, C certificate predicates, F adversarial variants, and R the reproducibility record.

$$\text{ValidRecipe}(\mathcal{E}) \iff H(I) \wedge A(I) \Downarrow O \wedge \bigwedge_{c \in C} c(O) \wedge \text{Replay}(R) = O.$$

Example depth:

$$E_0 \subset E_1 \subset E_2 \subset E_3 \subset E_4,$$

representing signature, minimal value, certificate inspection, connected workflow, and persistence/export replay.

64. Exact algebra and coordinate arrows

$$\text{grammar} \to \text{operator word} \to \text{realization} \to \text{seed hull} \to \gamma_{closure}.$$

$$x \xrightarrow{A} (x_r)_r \xrightarrow{T} (y_s)_s \xrightarrow{S} \hat{x}, \qquad \gamma : \hat{x} = x.$$

$$B_s \xrightarrow{B_t^{-1} B_s} C_{s \to t} \xrightarrow{c_t = C_{s \to t} c_s} B_t c_t = B_s c_s.$$

$$(E_n)_{n<N} \to c_F \to \widehat{E} \to \gamma_{rec}.$$

$$x \xrightarrow{A} c \xrightarrow{S^\dagger} x, \qquad c \sim c + z,\ z \in \ker S.$$

65. Arithmetic and sequence arrows

$$\text{name} \to \text{SequenceSpec} \to \text{strongest model} \to (a_n)_{n<N} \to \gamma.$$

$$f(x) \to \text{Mahler mask} \to \text{Cartier sections} \to \text{finite automaton}.$$

$$(n, p, k) \to B_n \bmod p^k \to v_p(\Delta) \to \gamma_{cong}.$$

$$(i, j, p, e, w) \to K_{i,j}^{(p^e)}(w) \to \text{valuation record}.$$

$$a \to (a_{qn+r})_{r=0}^{q-1} \to \hat{a} \to \gamma_{roundtrip}.$$

66. Signal-processing arrows

$$x \to \mathrm{STFT}_{w,h}(x) \to \mathrm{ISTFT}_{w,h}(X) \to \hat{x}, \quad \|x - \hat{x}\| \le \varepsilon.$$

$$\text{filter spec} \to h \to \text{stateful filter} \to (y_b)_b \to y.$$

$$x \xrightarrow{\uparrow L} x_L \xrightarrow{h} z \xrightarrow{\downarrow M} y \to \gamma_{rate}.$$

$$x \to \text{packet tree} \to \text{costs} \to \text{best leaves} \to \hat{x}.$$

$$y = x + \epsilon \to c \to \eta_\lambda(c) \to \hat{x} \to \gamma_{risk}.$$

$$y \to \text{candidate packets} \to \widehat{J} \to \hat{x} \to (H, \gamma_{recovery}).$$

67. Nonlinear and dynamics arrows

$$F, G \to J^m F, J^m G \to J^m(F \circ G) \to \gamma_{\text{Faà di Bruno}}.$$

$$F(x) = x \to \text{rooted trees} \to \text{majorant} \to \text{radius bound}.$$

$$x_k \to \text{defect} \to \mathrm{coker}(D) \to \mathrm{branches}_{k+1} \to \text{lift tree}.$$

$$(C, F^\bullet, d) \to E_r \to d_r \to E_{r+1} \to E_\infty.$$

$$P \to \text{partition} \to \bar{P} \to \text{Bayes update} \to \gamma_{sufficiency}.$$

$$H = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \to A - B(D - zI)^{-1}C \to \text{memory realization}.$$

68. Integration and expression arrows

$$p(x), [a,b] \to \mu_{[a,b]} \to \int p \, d\mu \in \mathbb{Q} \to \gamma_{exact}.$$

$$f, [a,b], H_4 \to Q_S(f) \pm B(H_4) \to \gamma_{bound}.$$

$$T(x) = Ax + b, \ \mu \to T_\# \mu, \qquad \int f \, d(T_\# \mu) = \int f \circ T \, d\mu.$$

$$e : \tau \to \mathrm{NF}(e) : \tau \to [e_1 = e_2].$$

$$(A_1, \dots, A_n) \to m[i,j] \to \text{plan} \to A_1 \cdots A_n.$$

$$e \to P(e) \to d(e) \to \text{loads}(P(e)) \to e' \to [e' \equiv e].$$

69. Quantum, deformation, and Langlands arrows

$$G \curvearrowright \mathcal{H} \to (P_\rho)_\rho \to \text{packet circuit} \to \gamma_{decomposition}.$$

$$\Phi, \mathcal{C}, \{E_a\} \to (P E_a^* E_b P)_{a,b} \to \gamma_{KL}.$$

$$\text{residual forest} \to \text{visible branches} \to \text{support packet}.$$

$$\text{Frobenius orbit} \to \text{tame packet} \to \text{Heisenberg model} \to \text{Clifford tower} \to \text{completion report}.$$

70. Export and reproducibility arrows

$$v \to D(v) \to \{R_f(D)\}_{f \in F} \to \text{bundle} \to \text{manifest check}.$$

$$\text{source} \to \text{gate} \to \{\text{wheel}, \text{sdist}, \text{zip}\} \to \text{clean extraction} \to \text{gate}.$$

Part XII. Verification, release, and reproducibility

71. Verification suites

Suite record:

$$V = (n, S, H, C, O, r), \qquad \mathrm{Pass}(V) \iff r = 0 \wedge \bigwedge_{c \in C} c = \top.$$

$$|\mathcal{V}| = 51.$$

Domain suite family:

$$\begin{aligned}\mathcal{V}_D = \{&\mathrm{core}, \mathrm{refinement}, \mathrm{nonlinear}, \mathrm{algorithms}, \mathrm{signals},\\ &\mathrm{dynamics}, \mathrm{analytic}, \mathrm{quantum}, \mathrm{arithmetic}, \mathrm{sequences},\\ &\mathrm{deformation}, \mathrm{langlands}-\mathrm{local}, \mathrm{langlands}-\mathrm{finite}-\mathrm{image},\\ &\mathrm{langlands}-\mathrm{completion}, \mathrm{langlands}, \mathrm{export}, \mathrm{generating},\\ &\mathrm{coordinates}, \mathrm{frame}-\mathrm{algebra}, \mathrm{integration}, \mathrm{expression},\\ &\mathrm{dsp}, \mathrm{hardening}, \mathrm{streaming}-\mathrm{beta}\}.\end{aligned}$$

Contract suite family:

$$\mathcal{V}_R = \{\mathrm{stable}, \mathrm{release}, \mathrm{gpu}, \mathrm{upgrade}, \mathrm{evidence}, \mathrm{documentation}, \mathrm{beta}\}.$$

Cumulative suites are the accepted `block2` through `block20` names plus `all`, enumerated exactly from `cli.contracts` in Appendix O.

Normalize checks and reports:

$$o = (n, p, d), \quad R = (s, v, (o_i)_i, p, d_R), \quad \lambda(R) = \{(o_i.n, o_i.d) : o_i.p = \bot\}.$$

Failure classes: assertion, validation exception, optional backend absence, required capability absence, resource refusal, crash, timeout, stale digest, and environment mismatch.

72. API, semantic, persistence, and upgrade contracts

72.1 API manifest

$$M_t = \{(q, k, s, o) : q \in \mathbb{S}\}, \quad t \in \{research, beta, stable\}.$$

$$\begin{aligned}\mathrm{NameExact}(M_t, S_t) &\iff \mathrm{names}(M_t) = S_t,\\ \mathrm{SignatureExact}(M_t, S_t) &\iff \forall q : \ s_M(q) = s_R(q),\\ \mathrm{OwnerResolvable}(M_t) &\iff \forall q : \mathrm{import}(o(q)) \Downarrow .\end{aligned}$$

72.2 Stable alias identity

$$\forall q \in \mathcal{S}_{stable} : \mathrm{id}(stable.q) = \mathrm{id}(v1.q) = \mathrm{id}(api.v1.q).$$

72.3 Closed semantic fixture

$$G = (v, s, \{(i, x_i, y_i, d_i)\}_{i=1}^{m}).$$

$$\mathrm{SemanticPass}(G) \iff \forall i : \mathrm{Canon}(f_i(x_i)) = y_i \wedge \mathrm{SHA}(y_i) = d_i.$$

72.4 Aggregate stable contract

$$\text{StablePass} = \text{ApiPass} \wedge \text{SemanticPass} \wedge \text{PersistencePass}\,.$$

72.5 Release and upgrade contracts

Artifact rows have the exact live shape

$$A_c = (\text{filename}, \text{sha256}, \text{count}).$$

The release contract is

$$\begin{aligned} R_c = (&\text{package_version}, \text{predecessor_version}, \text{release_line}, \text{stage}, \text{python_requires},\\ &\text{declared_python}, \text{required_platforms}, \text{stable_api}, \text{beta_api}, \text{research_api},\\ &\text{semantics}, \text{persistence}, \text{upgrade}, \text{evidence}, \text{documentation},\\ &\text{stable_aliases}, \text{required_cli_suites}, \text{schema}, \text{schema_version}). \end{aligned}$$

Its verifier binds artifact filenames, digests, and counts to the live package:

$$\begin{aligned} \text{ReleaseContractPass} \iff\ &\text{ArtifactIdentity} \wedge \text{LiveApi} \wedge \text{LiveSemantics} \wedge \text{LivePersistence}\\ &\wedge \text{Upgrade} \wedge \text{Evidence} \wedge \text{Documentation} \wedge \text{AliasIdentity}\\ &\wedge \text{CLIRoutes} \wedge \text{SupportPolicy}\,. \end{aligned}$$

The accepted predecessor set and exact upgrade-record shape are

$$P = \{0.15.0a2, 0.16.0a2, 1.0.0b1, 1.0.0b2, 1.0.0b3\},$$

$$U = (\text{target_version}, P, \text{stable_api}^*, \text{stable_semantics}, \text{portable_codecs}, \text{fixtures}^*, \text{schema}, \text{schema_version}).$$

The committed contract contains five stable-API baselines, one `0.16.0a2` semantic baseline, one `0.16.0a2` 51-codec baseline, and seven digest-bound portable fixtures. It does not assign a separate semantic or codec baseline to every predecessor.

$$\text{UpgradePass}(U) \iff \text{ArtifactIntegrity} \wedge \text{ApiRelations} \wedge \text{FixtureLoadable} \wedge \text{SemanticReplay} \wedge K_{0.16.0a2} \preceq K_{current}.$$

73. Platform and release qualification

Environment and evidence:

$$E = (python, implementation, executable, platform, machine, packages, backends, hardware, time),$$

$$\begin{aligned} E_v = (&\text{identifier}, \text{platform_key}, \text{platform}, \text{package_version}, \text{python}, \text{numpy},\\ &\text{source}, \text{source_sha256}, \text{inherited_via_upgrade_contract}, \text{results}, \text{optional}). \end{aligned}$$

$$\text{DeclaredSupported}(E) \not\equiv \text{ExecutedSuccessfully}(E, R) \not\equiv \text{HardwareQualified}(E, H).$$

Implemented currentness is package-version based, while source integrity is checked separately:

$$\text{CurrentPlatform}(E_v) \iff E_v.\text{package_version} = __version__,$$

$$\text{SHA256}(\text{data}/E_v.\text{source}) = E_v.\text{source_sha256}.$$

For the archived reference handoff,

$$\text{current} = \{\text{linux–!x86_64}\}, \qquad \text{missing_current} = \{\text{windows–!x86_64}\}.$$

Thus `check_validation_evidence()` passes the beta policy, while `check_validation_evidence(require_current_all_platforms=True)` fails.

Qualification:

$$Q = Q_{alias} \wedge Q_{api} \wedge Q_{semantic} \wedge Q_{analysis/synthesis} \wedge Q_{transfer} \wedge Q_{polyphase} \wedge Q_{arithmetic} \wedge Q_{persistence} \wedge Q_{settings} \wedge Q_{release} \wedge Q_{upgrade} \wedge Q_{evidence} \wedge Q_{support} \wedge Q_{python} \wedge Q_{version}.$$

$$Q(g, r) = Q \wedge (g \Rightarrow Q_{gpu_observed}) \wedge (r \Rightarrow Q_{gpu_passed}).$$

$$B_{ready} = Q \wedge Q_{documentation} \wedge Q_{beta_version} \wedge Q_{contracts}.$$

Windows qualification transcript recorded in the archived source:

$$N_{pass} = 1148, \qquad N_{skip} = 4, \qquad N_{fail} = 0,$$

$$\text{StrictMkDocs} = \top, \quad d_R = \text{4aed4f725e7592d0783ede586b7940dc80374fbe67123bf1acd507520c26e2e3}.$$

The four skips are optional JAX/PyTorch cases. This transcript was supplied from an external Windows replay. Its JSON record was not committed in the archived handoff. The cited `BLOCK21_WINDOWS_HOTFIX1_PROVENANCE.json` was also absent from that tree. Its committed evidence contract therefore inherited Windows evidence from `0.16.0a2`. Current-platform evidence requires importing and digest-binding the actual Windows JSON, then regenerating the evidence contract, release-contract artifact, and dependent handoff records. The separate committed Linux gate has report digest `9ece0eef69115b4519cfcc266eacb16d0881bfb3d3bc4b3b4d5c36e900ef46d5`.

74. Source publication handoff

74.1 Publication gate

The checks always appended form

$$G_{base} = G_{identity} \wedge G_{layout} \wedge G_{paths} \wedge G_{research\ api} \wedge G_{beta\ api} \wedge G_{stable\ api} \wedge G_{stable\ verify} \wedge G_{block20} \wedge G_{release} \wedge G_{upgrade} \wedge G_{evidence} \wedge G_{readiness} \wedge G_{tour} \wedge G_{links}.$$

For `full_tests` flag f and MkDocs mode $m \in \{\text{required}, \text{auto}, \text{skipped}\}$,

$$G_{21}(f, m) = G_{base} \wedge (f \Rightarrow G_{tests}) \wedge (m = \text{required} \Rightarrow G_{mkdocs}).$$

In auto mode, MkDocs becomes a check only when importable. Otherwise the report records a warning. The strict handoff prerequisite is distinct:

$$G_{21}^{strict} = G_{base} \wedge G_{tests} \wedge G_{mkdocs}.$$

74.2 Capability record

$$T = (schema, version, package, capabilities, passed, digest),$$

with polyphase refinement, analysis/synthesis, Euler/Fibonacci coordinates, finite integration, typed expression, and stable contract keys.

$$\text{SHA}(\text{Canon}(T \setminus \{digest\})) = T.digest.$$

74.3 Reproducible distributions and handoff

$$\text{Build}(S, N)_1 = (W_1, D_1), \quad \text{Build}(S, N)_2 = (W_2, D_2),$$

$$G_{repro-dist} = \text{ExactBytes}(W_1, W_2) \wedge \text{ExactBytes}(D_1, D_2).$$

Payload ledger:

$$L_S = \{(p, m, n, d) : p \in \text{Payload}(S)\}.$$

$$G_{archive} = G_{relative} \wedge G_{no-traversal} \wedge G_{no-symlink} \wedge G_{regular-only} \wedge G_{NFC} \wedge G_{casefold-unique} \wedge G_{excluded-local-state}.$$

$$G_{repro-zip} = \text{ExactBytes}(Z_1, Z_2).$$

74.4 Clean replay and wrapper arrows

$$Z \xrightarrow{\text{extract_safe}} S' \xrightarrow{G_{21}^{strict}} R'.$$

$$\begin{aligned} G_{replay} = G_{archive} &\wedge \text{Full}(R') \wedge \text{NamedChecks}(R') \wedge \text{SelfDigest}(R') \\ &\wedge \text{VersionMatch}(R') \wedge \text{InventoryMatch}(S', L_S) \wedge \text{PayloadHashes}(S', L_S) \\ &\wedge \text{EncodedModes}(S', L_S) \wedge \text{EmbeddedManifestEqual}(S', L_S). \end{aligned}$$

$$Z \to \text{venv} \to \text{wheel[publication]} \to \text{pip check} \to \text{preflight} \to \text{MkDocs} \to G_{21}^{strict}.$$

$$S \to G_{21}^{strict} \to G_{repro-dist} \to G_{repro-zip} \to G_{replay}.$$

74.5 Publication boundary

Qualified artifacts do not imply

$$\text{PyPIPublished} \vee \text{GitHubReleaseCreated} \vee \text{AuthenticatedTagCreated}\,.$$

74A. Source reconciliation

Forbidden in current instructions:

- predecessor wheel `0.16.0a2`
- a superseded wrapper as the canonical publication gate
- stale `support_matrix_0_16.json`
- `coordinates packet --size`
- `verify all` described as complete
- MkDocs described as PDF compilation
- historical evidence labeled current
- a license description inconsistent with the declared release license

$$G_{reconcile} = \forall f \in F_{stale} : f \notin \text{CurrentInstructions}\,.$$

Historical reproduction requires

$$\text{HistoricalLabel} = (version, date, purpose, replacement).$$

Part XIII. Exhaustive reference appendices

Appendices A through C. Stable, beta, and research symbol ledgers

Canonical symbol row:

$$S = (id, q, a, t, k, s, D, C, H, R, X, E, P, B, K, V, L).$$

Field	Required content
id	stable guide anchor
q	fully qualified public name
a	exported aliases
t	API tiers
k	class, function, data, enum, or protocol
s	exact normalized signature
D, C	mathematical domain and codomain
H	hypotheses and validation constraints

Field	Required content
R	return/result schema
X	exceptions and failure set
E	exactness and certificate semantics
P	persistence/export support
B	backend/dependency profile
K	complexity/resource notes
V	verifying tests and suites
L	related symbols and recipes

$$|S_{stable}| = 131, \qquad |S_{beta}| = 83, \qquad |S_{research}| = 1312.$$

$$\mathrm{Cov}(T) = \frac{|\{q \in T : \exists\, \mathrm{CompleteSymbolRow}(q)\}|}{|T|}.$$

$$\mathrm{Cov}_{Block14}(stable) = 1, \qquad \mathrm{Cov}_{Block14}(beta), \mathrm{Cov}_{Block14}(research) \text{ are not yet closed.}$$

The all-three equality is a normative coverage requirement, not evidence that a particular execution supplied every record.

Alias quotient:

$$q_1 \sim q_2 \iff \mathrm{id}(\mathrm{resolve}(q_1)) = \mathrm{id}(\mathrm{resolve}(q_2)).$$

$$\pi : S_{exports} \to S_{exports}/\sim .$$

Alias row:

$$A = (alias, canonical, identity_equal, tiers, deprecated, replacement).$$

Appendix D. Module reference ledger

$$M = (module, public, owner, domain, exports, tiers, optional_deps, examples, tests, docs, status).$$

$$|M_{implementation}| = 201, \qquad \forall m \in M_{implementation} : \exists!\, \mathrm{ModuleAnchor}(m).$$

Internal modules receive maintainer rows but no public cards.

Appendix E. Executable-example crosswalk

$$E = (path, language, anchor, symbols, imports, H, I, A, O, C, F, R, D, T).$$

Add dependency profile, platform, runtime class, deterministic seed, working directory, artifact hashes, cleanup behavior, tests, and historical/current status.

$$|E_{python}| = 57, \qquad |E_{powershell}| = 8.$$

$$\begin{aligned} G_{example-anchor} &= \forall e : \exists! a(e), \\ G_{example-symbol} &= \forall e : \mathrm{symbols}(e) \neq \emptyset, \\ G_{example-test} &= \forall e : \exists t(e) \text{ or documented manual gate}, \\ G_{example-replay} &= \forall e : \mathrm{Replay}(e) = \mathrm{Expected}(e). \end{aligned}$$

Source of truth:

$$\mathrm{paths}(E) = \mathrm{Files}(\text{examples/*.py}) \cup \mathrm{Files}(\text{examples/*.ps1}).$$

Appendix F. Complete CLI option matrix

$$C = (path, positionals, options, defaults, choices, decoder, output, exit, writes, force, ps, posix, tests).$$

$$\mathcal{C}_{CLI} = \text{WalkSubparsers}(\text{build_parser}()), \qquad \text{paths}(C) = \mathcal{C}_{CLI}.$$

Every row includes one successful invocation and one invalid-input invocation.

Appendix G. Portable schemas and migrations

Codec row:

$$K = (tag, version, type, encoder_shape, decoder_shape, migrations, digest, limits, examples, tests).$$

Migration row:

$$M = (tag, from, to, input_schema, output_schema, total, lossless, fixture, test).$$

$$|K| = 51, \quad |M| = 1, \quad \text{tags}(K) = \text{portable_codecs}().tags.$$

Appendix H. Certificate and theorem-ID index

$$T = (theorem_id, symbol, status, H, checked, unchecked, residuals, diagnostics, example, suite).$$

$$\forall id : \exists! T(id), \qquad \forall \gamma.theorem_id \neq \emptyset : \exists T(\gamma.theorem_id).$$

Appendix I. Exceptions and diagnostics

$$X = (exception, base, predicate, meaning, recovery, example, cli_exit, tests).$$

Required families:

- mathematical validation
- dimension/relation mismatch
- unavailable backend
- exactness loss
- failed assumptions
- resource refusal
- planned feature
- persistence/schema/tamper failure
- export/compiler/path failure

Appendix J. Backend and dependency matrix

$$D = (capability, base, extra, package, min_version, native, platform, probe, fallback, required_by).$$

$$B = (name, operations, exactness, dtypes, devices, availability, selection, tests, limits).$$

$$\text{installed} \neq \text{importable} \neq \text{device available} \neq \text{qualified}.$$

Appendix K. Complexity and resource budgets

$$K = (symbol, input_parameters, time, memory, exact_growth, backend, guard, empirical_fixture).$$

$$T(n, m, p), \quad M(n, m, p), \quad B_{depth}, \quad B_{nodes}, \quad B_{bytes}.$$

Unmeasured asymptotics remain symbolic and are not presented as benchmarks.

Appendix L. Migration and deprecation

$$L = (old, new, introduced, deprecated, removed, adapter, semantic_change, recipe, test).$$

$$L = L_{current} \sqcup L_{historical}.$$

Appendix M. Glossary and notation

$$N = (glyph, spoken, definition, first_anchor, domain, collisions, see_also).$$

$$G = (term, definition, package_meaning, classical_meaning, anchors, symbols).$$

Appendix N. Documentation-source crosswalk

$$D = (path, version, status, target_anchors, claims, commands, stale_tokens, resolution).$$

$$\text{status}(D) \in \{current, merged, historical, superseded, corrected\}.$$

$$\forall d \in \text{MkDocsSources} : \exists! \, \text{CrosswalkRow}(d).$$

Appendix O. Test and verification crosswalk

$$T = (nodeid, module, symbols, claims, examples, dependencies, platform, markers, result, suite).$$

$$V = (name, runner, child_suites, tests, claims, expected_count, current, status).$$

$$\text{TestsSymbol}(t, s), \quad \text{TestsExample}(t, e), \quad \text{VerifiesClaim}(t, c), \quad \text{BelongsToSuite}(t, v).$$

$$U = \{s \in S_{public} : \nexists t : \text{TestsSymbol}(t, s)\}.$$

Release acceptance requires $U = \emptyset$ or an explicit justified documentation-only class.

Part XIV. Documentation standards and design specifications

75. Stage 1: symbolic architecture

$$I_1 = (source, manifests, cli, examples, tests, docs, schemas, release\ artifacts).$$

$$I_1 \to (L_{symbols}, L_{modules}, L_{cli}, L_{examples}, L_{schemas}, L_{claims}, L_{tests}).$$

$$G_1 = G_{counts} \wedge G_{aliases} \wedge G_{anchors} \wedge G_{crosswalks} \wedge G_{reconcile}.$$

No prose drafting begins for an incomplete domain ledger.

76. Stage 2: function cards

$$(manifest, object, source, docs, tests) \to \text{SymbolCard}.$$

$$\text{CompleteCard}(s) \iff \bigwedge_{f \in \{q,t,k,s,D,C,H,R,X,E,P,B,K,V,L\}} f(s) \neq \text{missing}.$$

Explicit `not applicable`, `not measured`, or `not supported` is allowed. Silent blanks are not.

$$G_2 = \forall s \in S_{public} : \text{CompleteCard}(s).$$

77. Stage 3: executable examples

$$N = (id, source, environment, command, stdout, stderr, artifacts, returncode, digest).$$

$$\text{Run}(N, E) = (o, e, a, r, t, d).$$

$$G_3 = \forall N : r = 0 \wedge \text{ExpectedOutput}(N, o) \wedge \text{ExpectedArtifacts}(N, a).$$

Platform-specific snippets carry a platform predicate rather than a silent skip.

$$G_{adv} = \forall f \in \text{InterfaceFamilies} : |A_f| \geq 1.$$

78. Stage 4: connected tutorials

$$T = (goal, prerequisites, objects, steps, checkpoints, final\ claim, replay, extensions).$$

$$G_4 = \forall T : \text{CleanWheelReplay}(T) \wedge \text{ClaimMatchesCertificate}(T).$$

Provide $T_{Windows}$ and T_{POSIX} for shell-sensitive workflows.

79. Stage 5: reference validation

Coverage vector:

$$\mathbf{c} = (c_s, c_b, c_r, c_{cli}, c_e, c_k, c_m, c_d, c_t), \qquad \mathbf{c} = \mathbf{1}.$$

$$G_{links} = \forall \ell \in \text{LocalLinks} : \text{TargetExists}(\ell).$$

$$G_{anchors} = \text{Unique}(\text{Anchors}) \wedge \forall r \in \text{Refs} : r \in \text{Anchors}\,.$$

$$G_{claims} = \forall c : \text{Status}(c) \wedge \text{Hypotheses}(c) \wedge \text{Limitations}(c) \wedge \text{VerificationRef}(c).$$

$$G_{drift} = L_{committed} = \text{GenerateLedgers}(source).$$

80. Stage 6: publication formats

80.1 Canonical-source graph

$$\text{Markdown}_{canonical} \to \begin{cases} \text{MkDocs HTML}, \\ \text{LaTeX}_{curated} \to \text{PDF}, \\ \text{coverage.json}, \\ \text{symbol_index.json}. \end{cases}$$

80.2 HTML gate

$$G_{html} = G_{mkdocs-strict} \wedge G_{links} \wedge G_{assets} \wedge G_{navigation} \wedge G_{search-index}.$$

Observe return code 0, resolved navigation, resolved links, present assets, preserved mathematics, and searchable symbol anchors.

80.3 PDF gate

$$G_{pdf} = G_{latex-render} \wedge G_{compile} \wedge G_{nonempty} \wedge G_{fonts} \wedge G_{figures} \wedge G_{tables} \wedge G_{toc} \wedge G_{index} \wedge G_{visual-QA}.$$

$$Q_{pdf} = (pages, rendered\ images, overflow, clipping, orphans, figure\ scale, table\ fit, pass).$$

Before the PDF stage, reflow every long tuple and conjunction with `aligned`, `gathered`, or `multline`. Symbolic delimiter balance and successful compilation do not imply that display boxes fit the page. The rendered-page audit must observe zero material overflow or clipping.

$$G_{html} \not\Rightarrow G_{pdf}, \qquad G_{pdf} \not\Rightarrow G_{html}.$$

80.4 Build record and reproducibility

$$P_g = (schema, version, source\ digest, commit, toolchain, counts, gates, artifacts, time).$$

$$A = (name, path, media\ type, size, sha256, reproducible).$$

$$\text{GuideBuild}(S, N)_1 = \text{GuideBuild}(S, N)_2$$

when toolchains permit byte normalization. Otherwise require semantic and rendered-page identity with a documented normalization boundary.

81. Definition of done

$$\begin{aligned} G_{guide} = {} & G_1 \wedge G_2 \wedge G_3 \wedge G_4 \wedge G_{links} \wedge G_{anchors} \wedge G_{claims} \wedge G_{drift} \\ & \wedge G_{html} \wedge G_{pdf} \wedge G_{reconcile} \wedge G_{example-replay} \wedge G_{cli} \wedge G_{schema} \wedge G_{tests}. \end{aligned}$$

$$\begin{gathered} \text{Cov}(\mathcal{S}_{stable}) = 1, \qquad \text{Cov}(\mathcal{S}_{beta}) = 1, \quad \text{Cov}(\mathcal{S}_{research}) = 1, \\ \text{Cov}(\mathcal{C}_{CLI}) = 1, \quad \text{Cov}(\mathcal{E}_{examples}) = 1, \quad \text{Cov}(\mathcal{K}_{codecs}) = 1, \\ \text{Cov}(\mathcal{V}_{suites}) = 1, \quad \text{Cov}(\mathcal{D}_{sources}) = 1. \end{gathered}$$

$$\forall n \in \text{Snippets} : \text{Run}(n, \text{DeclaredEnvironment}(n)).passed.$$

$$\forall c \in \text{Claims} : \text{WordingStrength}(c) \leq \text{EvidenceStrength}(c).$$

Finite certificates remain finite. Numerical residuals remain tolerance-qualified. Optional backend skips remain skips. Historical evidence remains historical.

$$\mathcal{A}_{guide} = \{\text{source.md}, \text{site/}, \text{user_guide.pdf}, \text{coverage.json}, \text{symbol_index.json}, \text{build_record.json}, \text{SHA256SUMS}\}.$$

$$\boxed{\text{CompleteGuide} \iff G_{guide} \wedge \forall a \in \mathcal{A}_{guide} : \text{Exists}(a) \wedge \text{Nonempty}(a) \wedge \text{DigestRecorded}(a)}$$

Specification boundary

These specifications preserve object schemas, domains and codomains, workflow arrows, resource and validity invariants, verification predicates, coverage ledgers, example fields, and independent HTML/PDF requirements. Explanations and observed outputs must agree with this architecture and the more precise implemented contracts.
