Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExpressionType`. Reflected implementation `types.UnionType`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-TYPE`.

Manifest signature (s).

```
null
```

Definition. A PEP 604 union alias for `CoordinateSpace | LinearMapType`.

Contract (D, C, H, R, X). Import returns a runtime PEP 604 union object used by annotations and type checks. It is not a factory and has no project-defined constructor contract. Values must be instances of one of the listed exact expression-space classes. Unsupported values are rejected by the consuming expression APIs, not by importing the alias.

Guarantees (E, P, B, K). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block20_expression_calculus.py` cover this route. See Chapters 50 and 52.

C.1A · KomorebiDeprecationWarning

Identity (q, a, t, k). Public research-manifest route `komorebi_math.KomorebiDeprecationWarning`. Reflected implementation `komorebi_math.compatibility.KomorebiDeprecationWarning`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `class`. Profile `C1-DEPRECATION-WARNING`.

Manifest signature (s).

```
null
```

Definition. The package-specific warning category used for explicit public API deprecations.

Contract (D, C, H, R, X). The class is a `DeprecationWarning` subclass used as a category, not an emitted warning instance. Normal Python warning filters therefore apply. The manifest records a literal `null` signature because the class exposes no project-defined constructor contract.

Guarantees (E, P, B, K). The category adds no runtime dependency beyond Python's warning system. Filtering, display, and escalation to errors follow the caller's warning policy. Class lookup is constant-time and has no backend or platform-specific branch.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7 and 72.

C.1A · PACKET_JET_CHUNK_SCHEMA

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PACKET_JET_CHUNK_SCHEMA`. Reflected implementation `builtins.str`. The same object is available through the curated beta route `komorebi_math.beta.PACKET_JET_CHUNK_SCHEMA`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-META`.

Manifest signature (`s`).

```
null
```

Definition. The schema identifier `komorebi-math.packet-jet-stream.chunk` for one independently digested packet-jet stream chunk.

Contract (`D, C, H, R, X`). Import has no arguments and returns the recorded immutable schema string or integer. The binding names the accepted stream or chunk envelope but performs no I/O and does not validate a directory. Stream readers and writers enforce the value. There is no call-time exception.

Guarantees (`E, P, B, K`). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (`V, L`). The committed manifest, runtime reflection audit, and `test_block11_streaming_migrations.py` cover this route. See Chapters 4, 7, 43, 52, and 72 as applicable.

C.1A · `PACKET_JET_CHUNK_SCHEMA_VERSION`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.PACKET_JET_CHUNK_SCHEMA_VERSION`. Reflected implementation `builtins.int`. The same object is available through the curated beta route `komorebi_math.beta.PACKET_JET_CHUNK_SCHEMA_VERSION`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-META`.

Manifest signature (`s`).

```
null
```

Definition. The integer `1`, the accepted packet-jet chunk schema version.

Contract (`D, C, H, R, X`). Import has no arguments and returns the recorded immutable schema string or integer. The binding names the accepted stream or chunk envelope but performs no I/O and does not validate a directory. Stream readers and writers enforce the value. There is no call-time exception.

Guarantees (`E, P, B, K`). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (`V, L`). The committed manifest, runtime reflection audit, and `test_block11_streaming_migrations.py` cover this route. See Chapters 4, 7, 43, 52, and 72 as applicable.

C.1A · `PACKET_JET_STREAM_SCHEMA`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.PACKET_JET_STREAM_SCHEMA`. Reflected implementation `builtins.str`. The same object is available through the curated beta route `komorebi_math.beta.PACKET_JET_STREAM_SCHEMA`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-META`.

Manifest signature (`s`).

```
null
```

Definition. The schema identifier `komorebi-math.packet-jet-stream` for a resumable packet-jet directory manifest.

Contract (`D, C, H, R, X`). Import has no arguments and returns the recorded immutable schema string or integer. The binding names the accepted stream or chunk envelope but performs no I/O and does not validate a directory. Stream readers and writers enforce the value. There is no call-time exception.

Guarantees (`E, P, B, K`). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block11_streaming_migrations.py` cover this route. See Chapters 4, 7, 43, 52, and 72 as applicable.

C.1A · PACKET_JET_STREAM_SCHEMA_VERSION

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PACKET_JET_STREAM_SCHEMA_VERSION`. Reflected implementation `builtins.int`. The same object is available through the curated beta route `komorebi_math.beta.PACKET_JET_STREAM_SCHEMA_VERSION`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-META`.

Manifest signature (s).

```
null
```

Definition. The integer `1`, the accepted packet-jet stream-manifest schema version.

Contract (D, C, H, R, X). Import has no arguments and returns the recorded immutable schema string or integer. The binding names the accepted stream or chunk envelope but performs no I/O and does not validate a directory. Stream readers and writers enforce the value. There is no call-time exception.

Guarantees (E, P, B, K). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block11_streaming_migrations.py` cover this route. See Chapters 4, 7, 43, 52, and 72 as applicable.

C.1A · ProvenanceRecord

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ProvenanceRecord`. Reflected implementation `komorebi_math.provenance.ProvenanceRecord`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `class`. Profile `C1-PROV-RECORD`.

Manifest signature (s).

```
(identifier: 'str', title: 'str', status: 'ClaimStatus', source: 'str', assumptions: 'tuple[str, ...]' = (),
    ↪ limitations: 'tuple[str, ...]' = (), verification_suite: 'str | None' = None) -> None
```

Definition. An immutable provenance record containing an identifier, title, claim status, source, assumptions, limitations, and optional verification suite.

Contract (D, C, H, R, X). The constructor stores provenance metadata without resolving the cited source or running a verification suite. `to_dict()` returns dataclass fields with `status` converted to its string value. Assumptions and limitations remain explicit tuples supplied by the caller.

Guarantees (E, P, B, K). Provenance metadata is descriptive and does not prove the cited claim. Record lookup is constant-time for registered names and otherwise includes module import plus attribute traversal proportional to path length. The registry is process-local, backend-neutral, and unauthenticated.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_certificates_registry.py` and provenance-bearing domain tests cover this route. See Chapters 5 and 72.

C.1A · PublicApiManifest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PublicApiManifest`. Reflected implementation `komorebi_math.compatibility.PublicApiManifest`. The same object is available through the curated beta route `komorebi_math.beta.PublicApiManifest` and the curated stable routes `komorebi_math.stable.PublicApiManifest`, `komorebi_math.v1.PublicApiManifest`, and `komorebi_math.api.v1.PublicApiManifest`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `class`. Profile `C1-API-MANIFEST`.

Manifest signature (s).

```
(package_version: 'str', namespaces: 'tuple[str, ...]', symbols: 'tuple[PublicApiSymbol, ...]', schema: 'str' =
    ↪ 'komorebi-math.public-api', schema_version: 'int' = 1, stability_level: 'str' = 'pre-beta-additive') -> None
```

Definition. An immutable deterministic snapshot of selected public namespaces and their sorted `__all__` exports.

Contract (D, C, H, R, X). Construction requires the canonical schema and version, a nonempty unique namespace tuple, deterministically sorted unique symbols, and namespace containment. Violations raise `ValidationError`. `to_dict()` emits canonical manifest data, `from_dict()` validates the six top-level fields, `digest` computes SHA-256 over compact sorted JSON, and `symbol_map()` keys records by namespace and name.

Guarantees (E, P, B, K). The records are exact structural metadata, not semantic certificates. Storage is linear in the number and length of recorded symbols. Manifest sorting and canonical digest construction are `O(n log n)` in symbol count plus serialized size. Map construction is linear. The implementation uses the standard library and imports no optional numerical backend.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, 75, and 76.

C.1A · PublicApiSymbol

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PublicApiSymbol`. Reflected implementation `komorebi_math.compatibility.PublicApiSymbol`. The same object is available through the curated beta route `komorebi_math.beta.PublicApiSymbol` and the curated stable routes `komorebi_math.stable.PublicApiSymbol`, `komorebi_math.v1.PublicApiSymbol`, and `komorebi_math.api.v1.PublicApiSymbol`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `class`. Profile `C1-API-SYMBOL`.

Manifest signature (s).

```
(namespace: 'str', name: 'str', kind: 'str', implementation_module: 'str', qualname: 'str', signature: 'str |
    ↪ None') -> None
```

Definition. An ordered immutable record for one exported name, its broad kind, implementation owner, qualified name, and reflected signature text.

Contract (D, C, H, R, X). The direct dataclass constructor stores one symbol record. `to_dict()` emits the six schema fields. `from_dict()` requires exactly those fields and requires `signature` to be a string or `null`. Schema violations raise `ValidationError`. Ordering is lexicographic across dataclass fields and is used by manifest sorting.

Guarantees (E, P, B, K). The records are exact structural metadata, not semantic certificates. Storage is linear in the number and length of recorded symbols. Manifest sorting and canonical digest construction are `O(n log n)` in symbol count plus serialized size. Map construction is linear. The implementation uses the standard library and imports no optional numerical backend.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, 75, and 76.

C.1A · STAGES

Identity (q, a, t, k). Public research-manifest route `komorebi_math.STAGES`. Reflected implementation `builtins.tuple`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-STAGE`.

Manifest signature (s).

```
null
```

Definition. A nine-entry tuple of `StageSpec` records describing the common seed, address, operate, project, transfer, refine, constrain, complete, and reconstruct workflow.

Contract (D, C, H, R, X). Import returns a fixed tuple of nine immutable stage records. Each record contains a stage enum, a plain-language meaning, an `implemented_in_alpha` flag, and an owning module string. The `complete` stage is explicitly marked false in this release. The tuple is descriptive and does not execute a pipeline.

Guarantees (E, P, B, K). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and the unified-stage source audit and the Chapter 2 execution-language inventory cover this route. See Chapters 2 and 74.

C.1A · `Settings`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Settings`. Reflected implementation `komorebi_math.config.Settings`. The same object is available through the curated stable routes `komorebi_math.stable.Settings`, `komorebi_math.v1.Settings`, and `komorebi_math.api.v1.Settings`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `class`. Profile `C1-SETTINGS`.

Manifest signature (s).

```
(backend: 'str' = 'numpy', tolerance: 'float' = 1e-10, validate_on_construction: 'bool' = True) -> None
```

Definition. An immutable context-local settings record with defaults `backend='numpy'`, `tolerance=1e-10`, and `validate_on_construction=True`.

Contract (D, C, H, R, X). The constructor stores a backend label, numeric tolerance, and validation flag. It is a frozen dataclass and does not validate backend availability or tolerance sign. Runtime helpers place instances in a context variable rather than a process-wide mutable singleton.

Guarantees (E, P, B, K). The settings layer is standard-library only and context-local through `ContextVar`. Reads and replacements are constant-size for the three current fields. The backend label is descriptive here, so no automatic backend selection or fallback occurs. Determinism depends only on the current context and supplied values.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_certificates_registry.py` cover this route. See Chapters 3 and 8.

C.1A · `__version__`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.__version__`. Reflected implementation `builtins.str`. The same object is available through the curated beta route `komorebi_math.beta.__version__` and the curated stable routes `komorebi_math.stable.__version__`, `komorebi_math.v1.__version__`, and `komorebi_math.api.v1.__version__`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `data`. Profile `C1-META`.

Manifest signature (s).

```
null
```

Definition. The package version string recorded by the reference baseline: `1.0.0b4`.

Contract (D, C, H, R, X). Import returns the installed package version. Release and qualification helpers compare it with committed contracts. The string alone does not prove that a wheel, platform, or documentation build passed. There is no call-time exception.

Guarantees (E, P, B, K). The binding is deterministic package metadata and makes no independent mathematical claim. Import and lookup are constant-time in ordinary Python terms and use no numerical backend, accelerator, network, or filesystem operation. Any later file access or validation belongs to the consuming API.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and release-contract and qualification tests cover this route. See Chapters 4, 7, 43, 52, and 72 as applicable.

C.1A · check_beta_api

Identity (q, a, t, k). Public research-manifest route `komorebi_math.check_beta_api`. Reflected implementation `komorebi_math.compatibility.check_beta_api`. The same object is available through the curated beta route `komorebi_math.beta.check_beta_api`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-CHECK`.

Manifest signature (s).

```
(path: 'str | Path | None' = None) -> 'ApiCompatibilityReport'
```

Definition. Load the committed beta manifest, create the current beta manifest, and compare them with strict signatures enabled.

Contract (D, C, H, R, X). The function loads the committed or supplied beta manifest, creates the current beta manifest, and compares them with strict signatures enabled. Loading and reflection errors raise `ValidationError` or import errors. Structural incompatibility is represented by a false certificate rather than raised automatically.

Guarantees (E, P, B, K). The report is deterministic relative to the reference file and current imported namespace objects. Cost is the sum of manifest loading, reflection, sorting, and comparison. The check is backend-neutral and establishes structural compatibility only.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 73.

C.1A · check_public_api

Identity (q, a, t, k). Public research-manifest route `komorebi_math.check_public_api`. Reflected implementation `komorebi_math.compatibility.check_public_api`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-CHECK`.

Manifest signature (s).

```
(path: 'str | Path | None' = None, *, strict_signatures: 'bool' = False) -> 'ApiCompatibilityReport'
```

Definition. Load a reference manifest and compare it with the currently installed exports for the same namespace set.

Contract (D, C, H, R, X). The function loads the chosen reference manifest and compares it with current runtime exports. `strict_signatures` is forwarded unchanged. Loading, reflection, and comparison failures propagate. Otherwise the result may be compatible or incompatible without raising until its certificate is required.

Guarantees (E, P, B, K). The report is deterministic relative to the reference file and current imported namespace objects. Cost is the sum of manifest loading, reflection, sorting, and comparison. The check is backend-neutral and establishes structural compatibility only.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 73.

C.1A · compare_public_api

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compare_public_api`. Reflected implementation `komorebi_math.compatibility.compare_public_api`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-COMPARE`.

Manifest signature (s).

```
(reference: 'PublicApiManifest', current: 'PublicApiManifest | None' = None, *, strict_signatures: 'bool' = False)
   ↪  -> 'ApiCompatibilityReport'
```

Definition. Compare two manifests under the additive compatibility policy and return an exact structural report.

Contract (D, C, H, R, X). Both operands must be `PublicApiManifest` records covering identical namespaces. When `current` is omitted, the current exports for the reference namespaces are reflected. Additions are compatible. Removals and broad kind changes fail. Signature changes are always reported and fail only when `strict_signatures=True`. The returned exact certificate uses theorem ID `KM-API-010` and explicitly leaves semantic equivalence unchecked.

Guarantees (E, P, B, K). The certificate is exact for the reflected structural policy. Set and map construction are linear in manifest size, sorting differences adds `O(n log n)`, and memory is linear. No mathematical behavior, undocumented implementation detail, or platform qualification is inferred.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 75.

C.1A · configure

Identity (q, a, t, k). Public research-manifest route `komorebi_math.configure`. Reflected implementation `komorebi_math.config.configure`. The same object is available through the curated stable routes `komorebi_math.stable.configure`, `komorebi_math.v1.configure`, and `komorebi_math.api.v1.configure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-SETTINGS-SET`.

Manifest signature (s).

```
(*, backend: 'str | None' = None, tolerance: 'float | None' = None, validate_on_construction: 'bool | None' = None)
   ↪  -> 'Settings'
```

Definition. Replace selected fields in the active context's settings and return the new immutable `Settings` record.

Contract (D, C, H, R, X). Each omitted keyword preserves the current field. A supplied tolerance is converted with `float`, and the validation flag is converted with `bool`. The backend value is stored as supplied. The new record becomes active in the current context and is returned. Conversion errors propagate. Backend availability and tolerance range are not checked here.

Guarantees (E, P, B, K). The settings layer is standard-library only and context-local through `ContextVar`. Reads and replacements are constant-size for the three current fields. The backend label is descriptive here, so no automatic backend selection or fallback occurs. Determinism depends only on the current context and supplied values.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_certificates_registry.py` cover this route. See Chapters 3 and 8.

C.1A · create_beta_api_manifest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.create_beta_api_manifest`. Reflected implementation `komorebi_math.compatibility.create_beta_api_manifest`. The same object is available through the curated beta route `komorebi_math.beta.create_beta_api_manifest`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-CREATE`.

Manifest signature (s).

```
(*, package_version: 'str | None' = None) -> 'PublicApiManifest'
```

Definition. Build the curated `komorebi_math.beta` manifest and label it with the strict beta stability policy.

Contract (D, C, H, R, X). The function delegates reflection to `create_public_api_manifest` for `komorebi_math.beta`, then rebuilds the immutable manifest with `1.0-beta-additive-strict-signatures`. An optional package version overrides only the recorded version string. Reflection and validation failures propagate.

Guarantees (E, P, B, K). The result is deterministic for the same imported namespace objects and supported Python reflection behavior. Runtime is linear in exported names plus `O(n log n)` sorting. Memory is linear in the manifest. Reflection checks structure only. No optional numerical backend is used, though importing selected namespaces may execute their normal import code.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 75.

C.1A · `create_public_api_manifest`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.create_public_api_manifest`. Reflected implementation `komorebi_math.compatibility.create_public_api_manifest`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-CREATE`.

Manifest signature (s).

```
(namespaces: 'Sequence[str]' = ('komorebi_math', 'komorebi_math.nonlinear', 'komorebi_math.export',
    ↪  'komorebi_math.signals', 'komorebi_math.generating', 'komorebi_math.coordinates'), *, package_version: 'str
    ↪  | None' = None) -> 'PublicApiManifest'
```

Definition. Inspect selected namespaces at runtime and build a deterministically ordered public API manifest.

Contract (D, C, H, R, X). Namespaces are stripped, required to be nonempty and unique, imported in order, and required to define duplicate-free `__all__` names that resolve to attributes. Each export is classified as class, function, module, or data and receives reflected signature text where available. Path objects are normalized to `pathlib.Path`, generic aliases use a cross-version variadic signature, and final records are sorted. Invalid namespace declarations raise `ValidationError`. Import failures propagate.

Guarantees (E, P, B, K). The result is deterministic for the same imported namespace objects and supported Python reflection behavior. Runtime is linear in exported names plus `O(n log n)` sorting. Memory is linear in the manifest. Reflection checks structure only. No optional numerical backend is used, though importing selected namespaces may execute their normal import code.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 75.

C.1A · `deprecated`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.deprecated`. Reflected implementation `komorebi_math.compatibility.deprecated`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-DEPRECATION-DECORATOR`.

Manifest signature (s).

```
(*, since: 'str', replacement: 'str | None' = None, remove_in: 'str | None' = None, reason: 'str | None' = None) ->
    ↪  'Callable[[Callable[P, R]], Callable[P, R]]'
```

Definition. Create a decorator that preserves callable metadata, emits one structured deprecation warning on each call, and attaches a machine-readable deprecation record.

Contract (D, C, H, R, X). `since` is stripped and must be nonempty. The returned decorator accepts a callable, preserves its metadata with `functools.wraps`, attaches `__komorebi_deprecation__`, and returns a wrapper. Each invocation emits the structured warning and then returns or raises exactly as the wrapped callable does. Noncallable targets raise `ValidationError`.

Guarantees (E, P, B, K). The mechanism is standard-library only. Warning construction is linear in message length, and the wrapper adds constant bookkeeping plus the wrapped call's own cost. It does not remove an API, schedule deletion, or alter the wrapped result. Warning visibility depends on Python's active filters.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7 and 72.

C.1A · describe

Identity (q, a, t, k). Public research-manifest route `komorebi_math.describe`. Reflected implementation `komorebi_math.provenance.describe`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-PROV-DESCRIBE`.

Manifest signature (s).

```
(obj: 'Any') -> 'ProvenanceRecord | None'
```

Definition. Return a provenance record attached to an object or resolve a qualified-name string and inspect the resolved object's provenance attribute.

Contract (D, C, H, R, X). For an object, the function returns its `__komorebi_provenance__` attribute or `None`. For a string, it first checks the internal registry, then partitions the qualified name, imports the module, traverses attributes, and reads the same attribute. Missing modules, attributes, or unqualified strings return `None`. Unrelated import-time exceptions are not suppressed.

Guarantees (E, P, B, K). Provenance metadata is descriptive and does not prove the cited claim. Record lookup is constant-time for registered names and otherwise includes module import plus attribute traversal proportional to path length. The registry is process-local, backend-neutral, and unauthenticated.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_certificates_registry.py` and provenance-bearing domain tests cover this route. See Chapters 5 and 72.

C.1A · get_settings

Identity (q, a, t, k). Public research-manifest route `komorebi_math.get_settings`. Reflected implementation `komorebi_math.config.get_settings`. The same object is available through the curated stable routes `komorebi_math.stable.get_settings`, `komorebi_math.v1.get_settings`, and `komorebi_math.api.v1.get_settings`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-SETTINGS-GET`.

Manifest signature (s).

```
() -> 'Settings'
```

Definition. Return the active `Settings` value from the package's `ContextVar` in the current execution context.

Contract (D, C, H, R, X). The function has no arguments and returns the active immutable settings object for the current context. It performs no backend probe, allocation, or validation and raises no project exception under normal use.

Guarantees (E, P, B, K). The settings layer is standard-library only and context-local through `ContextVar`. Reads and replacements are constant-size for the three current fields. The backend label is descriptive here, so no automatic backend selection or fallback occurs. Determinism depends only on the current context and supplied values.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_certificates_registry.py` cover this route. See Chapters 3 and 8.

C.1A · load_behavioral_golden_fixture

Identity (q, a, t, k). Public research-manifest route `komorebi_math.load_behavioral_golden_fixture`. Reflected implementation `komorebi_math.golden.load_behavioral_golden_fixture`. The same object is available through the curated beta route `komorebi_math.beta.load_behavioral_golden_fixture`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-GOLDEN-LOAD`.

Manifest signature (s).

```
(path: 'str | Path | None' = None) -> 'tuple[Path, dict[str, Any], str]'
```

Definition. Load the closed behavioral fixture language, reject malformed or noncanonical JSON structures, and return the source path, validated document, and canonical SHA-256 digest.

Contract (D, C, H, R, X). The default is the committed fixture path. The loader requires valid UTF-8 JSON, rejects duplicate object keys and nonfinite constants, requires exactly `schema`, `schema_version`, and `cases`, enforces schema version 1, and requires a nonempty case array with unique nonempty names and at least `name`, `kind`, and `expected`. It returns a canonical SHA-256 digest over compact sorted JSON. File and validation failures raise `ValidationError`.

Guarantees (E, P, B, K). Canonical parsing and hashing are deterministic for the same fixture bytes after JSON normalization. Runtime and memory are linear in fixture size. SHA-256 identifies content but does not authenticate it. The loader executes no callable named by the fixture and uses no network access.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block11_golden_profiling_beta.py` cover this route. See Chapters 7 and 72.

C.1A · load_beta_api_manifest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.load_beta_api_manifest`. Reflected implementation `komorebi_math.compatibility.load_beta_api_manifest`. The same object is available through the curated beta route `komorebi_math.beta.load_beta_api_manifest`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-LOAD`.

Manifest signature (s).

```
(path: 'str | Path | None' = None) -> 'PublicApiManifest'
```

Definition. Load a public API manifest and additionally require the curated beta namespace set and beta stability label.

Contract (D, C, H, R, X). The function loads a public manifest, then requires the exact namespace tuple `('komorebi_math.beta',)` and the exact beta stability label. File, JSON, schema, ordering, namespace, and stability failures raise `ValidationError`.

Guarantees (E, P, B, K). Parsing, validation, and storage are linear in manifest size, with deterministic ordering checks. The implementation is standard-library only and performs no backend probe. It validates integrity of structure but provides no authenticity or cryptographic signature.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 75.

C.1A · load_public_api_manifest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.load_public_api_manifest`. Reflected implementation `komorebi_math.compatibility.load_public_api_manifest`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-LOAD`.

Manifest signature (s).

```
(path: 'str | Path | None' = None) -> 'PublicApiManifest'
```

Definition. Read, parse, and validate one public API manifest from UTF-8 JSON.

Contract (D, C, H, R, X). The default path is the committed public manifest. An explicit path is converted with `Path`. UTF-8 text must contain a JSON object matching the exact manifest fields and nested symbol schema. File errors, malformed JSON, wrong fields, duplicate or unsorted symbols, namespace mismatches, and unsupported schema values raise `ValidationError`.

Guarantees (E, P, B, K). Parsing, validation, and storage are linear in manifest size, with deterministic ordering checks. The implementation is standard-library only and performs no backend probe. It validates integrity of structure but provides no authenticity or cryptographic signature.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7, 72, and 75.

C.1A · run_behavioral_golden_fixture

Identity (q, a, t, k). Public research-manifest route `komorebi_math.run_behavioral_golden_fixture`. Reflected implementation `komorebi_math.golden.run_behavioral_golden_fixture`. The same object is available through the curated beta route `komorebi_math.beta.run_behavioral_golden_fixture`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-GOLDEN-RUN`.

Manifest signature (s).

```
(path: 'str | Path | None' = None) -> 'BehavioralGoldenReport'
```

Definition. Execute every fixture case through the fixed built-in runner registry and aggregate the case certificates into `KM-GOLDEN-011`.

Contract (D, C, H, R, X). The function loads the validated fixture, dispatches each `kind` through a closed built-in runner mapping, and rejects unknown kinds with `ValidationError`. It records each observed result, gathers failed names, and returns an exact aggregate certificate with theorem ID `KM-GOLDEN-011`. The committed fixture is representative rather than exhaustive.

Guarantees (E, P, B, K). The aggregate certificate is exact for the closed committed cases, not for the entire library. Total work and memory are the sum of the selected built-in case runners and retained results. Some runners use NumPy, but the fixture cannot import arbitrary code or select an external callable.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block11_golden_profiling_beta.py` cover this route. See Chapters 7 and 72.

C.1A · save_public_api_manifest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.save_public_api_manifest`. Reflected implementation `komorebi_math.compatibility.save_public_api_manifest`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-API-SAVE`.

Manifest signature (s).

```
(manifest: 'PublicApiManifest', path: 'str | Path', *, overwrite: 'bool' = False) -> 'Path'
```

Definition. Write one manifest as sorted, indented UTF-8 JSON with a final newline.

Contract (D, C, H, R, X). The first argument must be a `PublicApiManifest`. Parent directories are created. Existing destinations are rejected unless `overwrite=True`. The file is written as sorted two-space JSON with UTF-8, finite JSON values, LF newlines, and one final newline. The operation is deterministic but not an atomic-replace protocol. Filesystem errors propagate.

Guarantees (E, P, B, K). Output bytes are deterministic for one manifest and Python JSON semantics. Runtime and memory are linear in serialized manifest size. The routine uses the local filesystem only, performs no backend work, and provides neither atomic replacement nor authentication.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7 and 72.

C.1A · `settings_context`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.settings_context`. Reflected implementation `komorebi_math.config.settings_context`. The same object is available through the curated stable routes `komorebi_math.stable.settings_context`, `komorebi_math.v1.settings_context`, and `komorebi_math.api.v1.settings_context`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-SETTINGS-CTX`.

Manifest signature (s).

```
(**changes: 'object') -> 'Iterator[Settings]'
```

Definition. A context manager that temporarily replaces selected settings fields and restores the prior context token on exit.

Contract (D, C, H, R, X). Keyword names are passed to `dataclasses.replace` on the current settings record. The resulting record is installed, yielded, and the prior context token is restored in `finally`, including exceptional exits. Unknown fields or invalid replacement calls raise the standard `TypeError`.

Guarantees (E, P, B, K). The settings layer is standard-library only and context-local through `ContextVar`. Reads and replacements are constant-size for the three current fields. The backend label is descriptive here, so no automatic backend selection or fallback occurs. Determinism depends only on the current context and supplied values.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_certificates_registry.py` cover this route. See Chapters 3 and 8.

C.1A · `warn_deprecated`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.warn_deprecated`. Reflected implementation `komorebi_math.compatibility.warn_deprecated`. No stronger curated facade exports this name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. Stronger facade contracts apply only on the listed facade routes. Manifest kind `function`. Profile `C1-DEPRECATION-WARN`.

Manifest signature (s).

```
(name: 'str', *, since: 'str', replacement: 'str | None' = None, remove_in: 'str | None' = None, reason: 'str |
    ↪ None' = None, stacklevel: 'int' = 2) -> 'None'
```

Definition. Validate a deprecation name and version, construct a structured message, and emit `KomorebiDeprecationWarning`.

Contract (D, C, H, R, X). `name` and `since` are stripped and must remain nonempty or `ValidationError` is raised. Optional replacement, removal version, and reason clauses are appended to the message. `warnings.warn` receives the package category and requested stack level. The function returns `None`.

Guarantees (E, P, B, K). The mechanism is standard-library only. Warning construction is linear in message length, and the wrapper adds constant bookkeeping plus the wrapped call's own cost. It does not remove an API, schedule deletion, or alter the wrapped result. Warning visibility depends on Python's active filters.

Evidence and links (V, L). The committed manifest, runtime reflection audit, and `test_block10_compatibility.py`, `test_block11_golden_profiling_beta.py`, and the CLI compatibility tests cover this route. See Chapters 7 and 72.

C.1B Typed expression model, exact evaluation, planning, and portable encoding: 77 entries

This root section documents the complete root-export surface owned by the `komorebi_math.expression` implementation family. It covers the finite typed expression grammar, exact rational normal forms, evidence composition, basis-aware polynomial primitives, conservative certified rewrites, matrix-chain planning, a restricted five-opcode execution plan, and strict canonical expression transport. The scope is deliberately finite. It is not a general computer-algebra system, an arbitrary-code serialization format, or a numerical backend abstraction.

C.1B · `Apply`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.Apply`. Reflected implementation `komorebi_math.expression.model.Apply`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (`s`).

```
(operator: 'Expression', argument: 'Expression') -> None
```

Definition. An immutable expression node for applying a typed linear-map expression to a value expression in its declared source space.

Contract (`D, C, H, R, X`). Both operands must be expressions. The operator must have a `LinearMapType`, and the argument type must equal the operator source by complete semantic witness. The result type is the operator target.

Guarantees (`E, P, B, K`). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `CheckedExpression`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.CheckedExpression`. Reflected implementation `komorebi_math.expression.engine.CheckedExpression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-ENGINE-RECORD`.

Manifest signature (`s`).

```
(expression_type: 'CoordinateSpace | LinearMapType', stats: 'ExpressionStats', free_symbols: 'tuple[Symbol, ...]',
    ↪ certificate: 'Certificate') -> None
```

Definition. The result of structural type checking, carrying the semantic type, bounded graph statistics, sorted free symbols, and an exact checking certificate.

Contract (`D, C, H, R, X`). The frozen record stores already-computed fields. Its direct constructor does not rerun node replay or budget checks. Use `check_expression` for an authoritative record.

Guarantees (`E, P, B, K`). The record is immutable and backend-neutral, but direct dataclass construction is not an authority boundary unless the contract explicitly replays its fields. Authoritative constructors use exact rational data, SHA-256 content checks where stated, and certificates. No tolerance-based equality or floating fallback is used.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · Compose

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Compose`. Reflected implementation `komorebi_math.expression.model.Compose`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(factors: 'tuple[Expression, ...]') -> None
```

Definition. An immutable composition node whose map factors are stored from outermost to innermost.

Contract (D, C, H, R, X). The factor iterable is frozen as a tuple and must contain at least two expressions. Every factor must have a linear-map type. For adjacent outer and inner factors, the inner target must equal the outer source by complete semantic type. The resulting type runs from the innermost source to the outermost target.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · EquivalenceResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.EquivalenceResult`. Reflected implementation `komorebi_math.expression.engine.EquivalenceResult`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-ENGINE-RECORD`.

Manifest signature (s).

```
(equivalent: 'bool', left: 'NormalForm | None', right: 'NormalForm | None', certificate: 'Certificate') -> None
```

Definition. A finite exact equality decision with optional normal forms for both sides and a certificate for the comparison path.

Contract (D, C, H, R, X). The record stores a boolean decision, optional normal forms, and a certificate. `require_equivalent` first requires the certificate and then raises `ValidationError` when the decision is false.

Guarantees (E, P, B, K). The record is immutable and backend-neutral, but direct dataclass construction is not an authority boundary unless the contract explicitly replays its fields. Authoritative constructors use exact rational data, SHA-256 content checks where stated, and certificates. No tolerance-based equality or floating fallback is used.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · ExactMapLiteral

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactMapLiteral`. Reflected implementation `komorebi_math.expression.model.ExactMapLiteral`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(map_type: 'LinearMapType', matrix: 'Matrix', label: 'str' = '') -> None
```

Definition. An exact rational matrix literal with an explicit `LinearMapType` and a display-only label.

Contract (D, C, H, R, X). `map_type` must be a `LinearMapType`. Rows are consumed as finite iterables of integers or `Fraction` values with a common length. Shape must be `(target.dimension, source.dimension)`. The label is NFC-normalized display metadata and cannot activate polynomial rewrite rules.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `ExactValueLiteral`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactValueLiteral`. Reflected implementation `komorebi_math.expression.model.ExactValueLiteral`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(space: 'CoordinateSpace', entries: 'Vector') -> None
```

Definition. An exact rational coordinate vector inhabiting one supported coordinate space.

Contract (D, C, H, R, X). The space must be supported. Entries are consumed as a finite iterable, converted only from integers or `Fraction` values, and must have length equal to the space dimension. Shape or scalar violations raise `DimensionError` or `ValidationError`.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `Expression`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Expression`. Reflected implementation `komorebi_math.expression.model.Expression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
()
```

Definition. The abstract base class for the immutable typed expression grammar.

Contract (D, C, H, R, X). This base class defines the `expression_type` and `children` protocol. It has no public mutable state and is not itself a denotable concrete term. Calling the base `expression_type` property raises `NotImplementedError`.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · ExpressionBinding

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExpressionBinding`. Reflected implementation `komorebi_math.expression.certification.ExpressionBinding`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-CERT-RECORD`.

Manifest signature (s).

```
(value: 'Any', declared_type: 'Any', certificate: 'Certificate') -> None
```

Definition. A runtime value paired with its declared expression type and the certificate that qualifies the supplied evidence.

Contract (D, C, H, R, X). The declared type may not be `None`, and the certificate must be a `Certificate`. The direct constructor does not validate the shape or rationality of `value`. Consumers recheck it. Use `exact_binding` when exact built-in validation is required.

Guarantees (E, P, B, K). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · ExpressionBudget

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExpressionBudget`. Reflected implementation `komorebi_math.expression.model.ExpressionBudget`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-BUDGET`.

Manifest signature (s).

```
(max_nodes: 'int' = 10000, max_depth: 'int' = 1000, max_steps: 'int' = 50000, max_degree: 'int' = 512, max_entries:
    ↪  'int' = 1000000, max_coefficient_bits: 'int' = 1000000, max_serialized_bytes: 'int' = 64000000,
    ↪  max_symbol_length: 'int' = 1024) -> None
```

Definition. A fixed collection of pre-allocation limits for expression graph size, depth, work, degree, exact entries, coefficient bits, encoded size, and symbol length.

Contract (D, C, H, R, X). All eight limits must be positive integers other than `bool`. `preflight` performs iterative cycle detection, counts unique DAG nodes and edges, computes depth, validates child types, tracks polynomial degree, exact entries, coefficient bit size, structural encoded size, and symbol length, and raises `ResourceLimitError` when any bound is exceeded. `require` is an alias of `preflight`.

Guarantees (E, P, B, K). Preflight is deterministic for the in-memory DAG. Traversal is linear in unique nodes plus edges, with additional work linear in exact entries and basis witnesses. Memory is linear in visited nodes and distinct spaces. The limits are denial-of-service guards, not a proof that later rational matrix arithmetic will fit every external resource constraint.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · ExpressionPlan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExpressionPlan`. Reflected implementation `komorebi_math.expression.engine.ExpressionPlan`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-ENGINE-RECORD`.

Manifest signature (s).

```
(expression_digest: 'str', expression_type: 'CoordinateSpace | LinearMapType', instructions:
    ↪ 'tuple[PlanInstruction, ...]', output_index: 'int', scalar_operation_cost: 'int', plan_digest: 'str',
    ↪ certificate: 'Certificate') -> None
```

Definition. A self-contained, content-digested, topologically ordered exact execution plan for one typed expression.

Contract (D, C, H, R, X). The expression digest must be 64 hexadecimal characters. Instructions must be a nonempty tuple of `PlanInstruction` records whose dependencies point only backward. Each opcode's arity, payload, type, and scalar-operation cost is re-derived. Aggregate cost must equal the instruction sum, output index must be valid, and the canonical plan digest must match. Tampering raises `ValidationError`.

Guarantees (E, P, B, K). The record is immutable and backend-neutral, but direct dataclass construction is not an authority boundary unless the contract explicitly replays its fields. Authoritative constructors use exact rational data, SHA-256 content checks where stated, and certificates. No tolerance-based equality or floating fallback is used.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · ExpressionResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExpressionResult`. Reflected implementation `komorebi_math.expression.engine.ExpressionResult`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-ENGINE-RECORD`.

Manifest signature (s).

```
(normal_form: 'NormalForm', direct_normal_form: 'NormalForm', plan: 'ExpressionPlan', certificate: 'Certificate')
    ↪ -> None
```

Definition. The dual-path evaluation record containing planned and direct normal forms, the replayed plan, and their combined certificate.

Contract (D, C, H, R, X). `.value` exposes the planned normal-form data. `.scalar` is available only when the result type is `RationalSpace` and otherwise raises `DimensionError`. `.require()` requires the aggregate certificate before returning the exact data. The direct dataclass constructor does not compare the two paths.

Guarantees (E, P, B, K). The record is immutable and backend-neutral, but direct dataclass construction is not an authority boundary unless the contract explicitly replays its fields. Authoritative constructors use exact rational data, SHA-256 content checks where stated, and certificates. No tolerance-based equality or floating fallback is used.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `ExpressionStats`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExpressionStats`. Reflected implementation `komorebi_math.expression.model.ExpressionStats`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-BUDGET`.

Manifest signature (s).

```
(nodes: 'int', depth: 'int', steps: 'int', exact_entries: 'int', maximum_degree: 'int', maximum_coefficient_bits:
    ↪  'int', serialized_bytes: 'int') -> None
```

Definition. The finite structural totals returned by expression-budget preflight.

Contract (D, C, H, R, X). The frozen record stores seven integer totals. Its direct constructor is a reporting container and does not recompute a graph. Authoritative values are returned by `ExpressionBudget.preflight`.

Guarantees (E, P, B, K). Preflight is deterministic for the in-memory DAG. Traversal is linear in unique nodes plus edges, with additional work linear in exact entries and basis witnesses. Memory is linear in visited nodes and distinct spaces. The limits are denial-of-service guards, not a proof that later rational matrix arithmetic will fit every external resource constraint.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `IdentityMap`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.IdentityMap`. Reflected implementation `komorebi_math.expression.model.IdentityMap`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(space: 'CoordinateSpace') -> None
```

Definition. The typed identity map on one exact coordinate space.

Contract (D, C, H, R, X). The space must be supported. The node's type is `LinearMapType(space, space)`. Matrix data are not stored in the node and are generated during exact normalization.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · Let

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Let`. Reflected implementation `komorebi_math.expression.model.Let`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(symbol: 'Symbol', value: 'Expression', body: 'Expression') -> None
```

Definition. A lexical binding node that associates one identity-distinct `Symbol` with a value inside a typed body expression.

Contract (D, C, H, R, X). The binder must be an exact built-in `Symbol`. The value and body must be expressions, and the value type must equal the binder's declared type. The result type is the body type. Lexical resolution later uses binder identity, not the displayed name.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · LinearMapType

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LinearMapType`. Reflected implementation `komorebi_math.expression.model.LinearMapType`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-TYPE`.

Manifest signature (s).

```
(source: 'CoordinateSpace', target: 'CoordinateSpace') -> None
```

Definition. The exact hom-space type from one supported coordinate space to another.

Contract (D, C, H, R, X). Both endpoints must be built-in supported coordinate spaces. The semantic key includes the complete source and target witnesses. Matching dimensions or labels are insufficient. Invalid endpoints raise `TypeError`.

Guarantees (E, P, B, K). The record is immutable and backend-neutral. Semantic equality uses exact witnesses rather than display labels or approximate dimensions. Construction cost is linear in the supplied basis witness for polynomial spaces and constant for rational and map types. No floating arithmetic, user code execution, or GPU path is used.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · MatrixChainPlan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MatrixChainPlan`. Reflected implementation `komorebi_math.expression.planning.MatrixChainPlan`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-CHAIN-RECORD`.

Manifest signature (s).

```
(dimensions: 'tuple[int, ...]', tree: 'MatrixChainTree', scalar_operation_cost: 'int', left_associative_cost:
    ↪  'int', right_associative_cost: 'int', certificate: 'Certificate') -> None
```

Definition. The replay-validated optimal binary parenthesization record for one dense matrix-dimension chain.

Contract (D, C, H, R, X). Dimensions are normalized to at least two positive integers. The dynamic program is rerun, and the supplied tree, optimal cost, left cost, and right cost must match exactly. The certificate must be valid, unconditionally exact, assumption-complete, and use theorem ID `EXPR.PLAN.MATRIX_CHAIN_DP`.

Guarantees (E, P, B, K). The optimality claim is exact only for order-preserving binary parenthesizations under classical dense scalar-multiplication count. Planning uses `O(n^3)` time and `O(n^2)` table space for `n` matrices. It does not model additions, sparsity, rank, memory traffic, parallelism, GPU launches, Strassen-like algorithms, rounding error, or wall-clock time.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover matrix-chain optimum, tie breaking, exhaustive small-chain comparison, shape validation, exact multiplication, and plan tamper rejection. See Chapters 52 and 68.

C.1B · MatrixChainTree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MatrixChainTree`. Reflected implementation `komorebi_math.expression.planning.MatrixChainTree`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-CHAIN-RECORD`.

Manifest signature (s).

```
(start: 'int', end: 'int', split: 'int | None', rows: 'int', columns: 'int', scalar_operation_cost: 'int') -> None
```

Definition. The root interval and split decision for one node of a matrix-chain parenthesization.

Contract (D, C, H, R, X). Start, end, row count, column count, and cost are validated as nonnegative or positive integers as appropriate. A leaf interval has no split and zero cost. A nonleaf split must lie strictly inside its half-open interval. The direct record stores only one root decision, not the full split table.

Guarantees (E, P, B, K). The optimality claim is exact only for order-preserving binary parenthesizations under classical dense scalar-multiplication count. Planning uses `O(n^3)` time and `O(n^2)` table space for `n` matrices. It does not model additions, sparsity, rank, memory traffic, parallelism, GPU launches, Strassen-like algorithms, rounding error, or wall-clock time.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover matrix-chain optimum, tie breaking, exhaustive small-chain comparison, shape validation, exact multiplication, and plan tamper rejection. See Chapters 52 and 68.

C.1B · NormalForm

Identity (q, a, t, k). Public research-manifest route `komorebi_math.NormalForm`. Reflected implementation `komorebi_math.expression.certification.NormalForm`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-CERT-RECORD`.

Manifest signature (s).

```
(expression_type: 'Any', data: 'Any', digest: 'str', certificate: 'Certificate') -> None
```

Definition. Canonical exact vector or matrix data paired with its full semantic type, SHA-256 digest, and derivation certificate.

Contract (D, C, H, R, X). The digest must be a nonempty string and the evidence must be a `Certificate`. The direct constructor does not recompute the digest or revalidate data. Normalization and plan execution create authoritative records through internal checked constructors.

Guarantees (E, P, B, K). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · PlanInstruction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PlanInstruction`. Reflected implementation `komorebi_math.expression.engine.PlanInstruction`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-ENGINE-RECORD`.

Manifest signature (s).

```
(opcode: 'str', inputs: 'tuple[int, ...]', expression_type: 'CoordinateSpace | LinearMapType', payload: 'Any',
    ↪ scalar_operation_cost: 'int', certificate: 'Certificate') -> None
```

Definition. One typed instruction in the restricted exact execution language used by `ExpressionPlan`.

Contract (D, C, H, R, X). Opcode must be one of `constant`, `add`, `scale`, `matrix_chain`, or `apply`. Input indices and cost must be nonnegative integers, the type must be supported, and the evidence must be a `Certificate`. Full payload, dependency, type, and cost consistency is re-derived by `ExpressionPlan`.

Guarantees (E, P, B, K). The record is immutable and backend-neutral, but direct dataclass construction is not an authority boundary unless the contract explicitly replays its fields. Authoritative constructors use exact rational data, SHA-256 content checks where stated, and certificates. No tolerance-based equality or floating fallback is used.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · PolynomialCoordinateSpace

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolynomialCoordinateSpace`. Reflected implementation `komorebi_math.expression.model.PolynomialCoordinateSpace`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-TYPE`.

Manifest signature (`s`).

```
(variable: 'str', degree: 'int', basis: 'tuple[tuple[Fraction, ...], ...]', label: 'str' = '') -> None
```

Definition. A finite univariate polynomial coordinate space identified by its variable, degree, and complete exact graded-basis witness.

Contract (`D, C, H, R, X`). The variable is NFC-normalized and must be nonempty. Degree must be a nonnegative integer other than `bool`. The basis must contain exactly one finite rational polynomial of every degree from zero through the bound, member `j` must have length `j + 1`, and its leading coefficient must be nonzero. The display label is normalized but excluded from equality. `from_family` snapshots `family.polynomial(i)` exactly, and `truncate` permits only a compatible lower-degree prefix. Invalid witnesses raise `ValidationError`, `DimensionError`, or `TypeError`.

Guarantees (`E, P, B, K`). The record is immutable and backend-neutral. Semantic equality uses exact witnesses rather than display labels or approximate dimensions. Construction cost is linear in the supplied basis witness for polynomial spaces and constant for rational and map types. No floating arithmetic, user code execution, or GPU path is used.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `PolynomialPrimitive`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.PolynomialPrimitive`. Reflected implementation `komorebi_math.expression.polynomial.PolynomialPrimitive`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-POLY-RECORD`.

Manifest signature (`s`).

```
(kind: 'PrimitiveKind', map_type: 'LinearMapType', parameters: 'tuple[Fraction, ...]' = ()) -> None
```

Definition. A branded, replayable, basis-aware polynomial linear map with an enum kind, exact map type, rational parameters, and theorem identifier.

Contract (`D, C, H, R, X`). `kind` must be `PrimitiveKind`, `map_type` must be `LinearMapType`, and parameters are frozen and converted only from integers or `Fraction`. Kind-specific formation rules validate polynomial and rational endpoints, physical variables, degrees, basis extensions, interval order, density sign, and nonzero difference steps. `.matrix` and `.certificate()` replay rather than trust stored matrix data.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `PrimitiveKind`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.PrimitiveKind`. Reflected implementation `komorebi_math.expression.polynomial.PrimitiveKind`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-POLY-RECORD`.

Manifest signature (`s`).

```
(*values)
```

Definition. The nine-member string enumeration of supported replayable polynomial operations.

Contract (`D`, `C`, `H`, `R`, `X`). Construction follows `StrEnum` semantics. Accepted values are coordinate change, derivative, antiderivative, evaluation, interval integration, affine substitution, finite difference, boundary functional, and constant injection. Unknown values raise the standard enum `ValueError`.

Guarantees (`E`, `P`, `B`, `K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V`, `L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `RATIONAL_SPACE`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.RATIONAL_SPACE`. Reflected implementation `komorebi_math.expression.model.RationalSpace`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `data`. Profile `C1-EXPR-TYPE`.

Manifest signature (`s`).

```
null
```

Definition. The shared stateless instance of the one-dimensional exact rational coordinate space.

Contract (`D`, `C`, `H`, `R`, `X`). Import returns the shared `RationalSpace()` value. The class is stateless, so semantic equality and hashing do not depend on this particular object identity. The binding performs no arithmetic and raises no call-time exception.

Guarantees (`E`, `P`, `B`, `K`). The record is immutable and backend-neutral. Semantic equality uses exact witnesses rather than display labels or approximate dimensions. Construction cost is linear in the supplied basis witness for polynomial spaces and constant for rational and map types. No floating arithmetic, user code execution, or GPU path is used.

Evidence and links (`V`, `L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `RationalSpace`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.RationalSpace`. Reflected implementation `komorebi_math.expression.model.RationalSpace`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-TYPE`.

Manifest signature (`s`).

```
() -> None
```

Definition. The stateless one-dimensional coordinate space over the rational numbers.

Contract (`D, C, H, R, X`). Construction takes no arguments and produces a frozen stateless value with dimension one and semantic key `('Q',)`. All instances are semantically equal. The class does not coerce scalars or validate expression data by itself.

Guarantees (`E, P, B, K`). The record is immutable and backend-neutral. Semantic equality uses exact witnesses rather than display labels or approximate dimensions. Construction cost is linear in the supplied basis witness for polynomial spaces and constant for rational and map types. No floating arithmetic, user code execution, or GPU path is used.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `RewriteStep`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.RewriteStep`. Reflected implementation `komorebi_math.expression.certification.RewriteStep`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-CERT-RECORD`.

Manifest signature (`s`).

```
(rule: 'str', theorem_id: 'str | None', before_digest: 'str', after_digest: 'str', side_conditions: 'tuple[str,
   ↪  ...]', certificate: 'Certificate') -> None
```

Definition. One denotation-checked simplification step with before and after digests, side conditions, theorem ID, and certificate.

Contract (`D, C, H, R, X`). Rule and digest strings must be nonempty. A supplied theorem ID must be nonempty. Side conditions are deduplicated in first-seen order and must be nonempty strings. The certificate type is checked, but the direct constructor does not rerun the before-and-after denotations.

Guarantees (`E, P, B, K`). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · `Scale`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.Scale`. Reflected implementation `komorebi_math.expression.model.Scale`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(scalar: 'Fraction', value: 'Expression') -> None
```

Definition. An immutable rational scalar-multiplication node that preserves the type of its child expression.

Contract (D, C, H, R, X). The scalar is converted only from an integer or `Fraction`. Booleans and binary floats are rejected. The child must be an expression. The node preserves the child's exact type.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `SimplificationResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SimplificationResult`. Reflected implementation `komorebi_math.expression.engine.SimplificationResult`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-ENGINE-RECORD`.

Manifest signature (s).

```
(expression: 'Expression', before: 'NormalForm', after: 'NormalForm', steps: 'tuple[RewriteStep, ...]',
   ↪  certificate: 'Certificate') -> None
```

Definition. A conservative rewrite result containing the rewritten expression, exact normal forms before and after, the step ledger, and an aggregate certificate.

Contract (D, C, H, R, X). The record stores the rewritten expression, exact normal forms before and after, the immutable rewrite-step tuple, and the aggregate certificate. Its direct constructor is not a replay boundary. `simplify_expression` performs the authoritative checks.

Guarantees (E, P, B, K). The record is immutable and backend-neutral, but direct dataclass construction is not an authority boundary unless the contract explicitly replays its fields. Authoritative constructors use exact rational data, SHA-256 content checks where stated, and certificates. No tolerance-based equality or floating fallback is used.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `Sum`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Sum`. Reflected implementation `komorebi_math.expression.model.Sum`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(terms: 'tuple[Expression, ...]') -> None
```

Definition. An immutable finite sum node whose terms all have the same exact expression type.

Contract (D, C, H, R, X). The terms are frozen as a tuple and must contain at least two expressions. Every term must have exactly the same semantic expression type. Type disagreement or non-expression children raise a validation or type error.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `Symbol`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Symbol`. Reflected implementation `komorebi_math.expression.model.Symbol`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(name: 'str', declared_type: 'ExpressionType') -> None
```

Definition. An identity-distinct lexical or free variable with a normalized display name and an explicit declared expression type.

Contract (D, C, H, R, X). The name is NFC-normalized, stripped, and required to be nonempty. The declared type must be a built-in rational space, polynomial space, or linear-map type. Symbols deliberately use object identity rather than value equality, so same-name instances remain distinct binders.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `ZeroMap`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ZeroMap`. Reflected implementation `komorebi_math.expression.model.ZeroMap`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `class`. Profile `C1-EXPR-NODE`.

Manifest signature (s).

```
(map_type: 'LinearMapType') -> None
```

Definition. The exact zero linear map of one declared source and target type.

Contract (D, C, H, R, X). The supplied type must be a `LinearMapType`. The node stores no matrix data. Exact zero entries of the declared shape are produced during normalization.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_`

example.py cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · add

Identity (q, a, t, k). Public research-manifest route komorebi_math.add. Reflected implementation komorebi_math.expression.model.add. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by [RESEARCH] policy pre-beta-additive. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind function. Profile C1-EXPR-CONSTRUCTOR.

Manifest signature (s).

```
(*terms: 'Expression') -> 'Expression'
```

Definition. Construct a typed finite sum, returning its sole term unchanged when exactly one term is supplied.

Contract (D, C, H, R, X). At least one term is required. A sole term is type-checked and returned unchanged. Two or more terms produce Sum, which requires identical semantic types.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, tests/test_block20_expression_calculus.py, verification/block20_math_verifier.py, and examples/block20_typed_expression_worked_example.py cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · affine_substitution

Identity (q, a, t, k). Public research-manifest route komorebi_math.affine_substitution. Reflected implementation komorebi_math.expression.polynomial.affine_substitution. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by [RESEARCH] policy pre-beta-additive. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind function. Profile C1-EXPR-POLY-CONSTRUCTOR.

Manifest signature (s).

```
(source: 'PolynomialCoordinateSpace', scale: 'int | Fraction' = 1, shift: 'int | Fraction' = 0) ->
   ↪ 'PolynomialPrimitive'
```

Definition. Construct the endomorphism that sends a polynomial to p(scale*x + shift) in the same basis-aware coordinate space.

Contract (D, C, H, R, X). Source must be a polynomial coordinate space. Scale and shift are converted to Fraction. The map is an endomorphism of the same coordinate space, including the zero-scale case.

Guarantees (E, P, B, K). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, tests/test_block20_expression_calculus.py, verification/block20_math_verifier.py, and examples/block20_typed_expression_worked_example.py cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · antiderivative

Identity (q, a, t, k). Public research-manifest route `komorebi_math.antiderivative`. Reflected implementation `komorebi_math.expression.polynomial.antiderivative`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (s).

```
(source: 'PolynomialCoordinateSpace', target: 'PolynomialCoordinateSpace', basepoint: 'int | Fraction' = 0) ->
    ↪ 'PolynomialPrimitive'
```

Definition. Construct the basepoint-normalized polynomial antiderivative from a source space to an exact one-degree extension.

Contract (D, C, H, R, X). Source and target must use the same variable. Target degree must be exactly one larger and its truncation must equal the full source witness. The basepoint is converted to `Fraction`.

Guarantees (E, P, B, K). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · apply

Identity (q, a, t, k). Public research-manifest route `komorebi_math.apply`. Reflected implementation `komorebi_math.expression.model.apply`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(operator: 'Expression', argument: 'Expression') -> 'Apply'
```

Definition. Construct a checked `Apply` node from a linear-map expression and a compatible value expression.

Contract (D, C, H, R, X). The function delegates to `Apply`. It does not normalize either operand. Source-target compatibility is enforced immediately.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · boundary_functional

Identity (q, a, t, k). Public research-manifest route `komorebi_math.boundary_functional`. Reflected implementation `komorebi_math.expression.polynomial.boundary_functional`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (s).

```
(source: 'PolynomialCoordinateSpace', lower: 'int | Fraction', upper: 'int | Fraction', density: 'int | Fraction' =
    ↪ 1) -> 'PolynomialPrimitive'
```

Definition. Construct the exact functional `density * (p(upper) - p(lower))` on a polynomial coordinate space.

Contract (D, C, H, R, X). Source must be a polynomial coordinate space. Lower, upper, and density are converted to `Fraction`. Lower must not exceed upper and density must be nonnegative. The target is `RATIONAL_SPACE`.

Guarantees (E, P, B, K). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `check_expression`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.check_expression`. Reflected implementation `komorebi_math.expression.engine.check_expression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(expression: 'Expression', bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' = None, *, budget:
    ↪ 'ExpressionBudget | None' = None) -> 'CheckedExpression'
```

Definition. Replay the exact node invariants, enforce the resource budget, validate supplied bindings, and report the expression type and free symbols.

Contract (D, C, H, R, X). The root must be an `Expression`, and a supplied budget must be exactly `ExpressionBudget`. Built-in node invariants are replayed, cycles and forged children are rejected, and budget preflight runs. Bindings must map strings or identity-specific symbols to `ExpressionBinding` records. Conflicting, ambiguous, ill-shaped, or mistyped bindings fail. Missing free bindings are reported but do not make an open term ill typed.

Guarantees (E, P, B, K). The check is exact for the finite built-in grammar and supplied bindings. Work is bounded by the graph budget and is linear in the traversed graph plus binding lookup overhead. It establishes structural typing and free-symbol accounting, not a denotation for an open term.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `compile_expression`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compile_expression`. Reflected implementation `komorebi_math.expression.engine.compile_expression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(expression: 'Expression', bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' = None, *, budget:
    ↪ 'ExpressionBudget | None' = None) -> 'ExpressionPlan'
```

Definition. Compile a closed typed expression into a replayable exact instruction plan and refuse the plan unless it matches independent direct normalization.

Contract (D, C, H, R, X). The source is checked and directly normalized. The compiler emits only the five supported opcodes, uses dynamic programming for flattened map chains, computes source and plan digests, creates a certificate, executes the plan, and compares the result with direct normalization. It returns only after exact type and data agreement.

Guarantees (E, P, B, K). The execution language is closed to five opcodes and uses exact rational operations. Compilation and evaluation include independent replay checks and content digests. Matrix-chain planning is cubic in chain length with quadratic tables. Matrix arithmetic and coefficient growth dominate execution. Plan digests are integrity checks, not signatures or authenticated transport.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · compose

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compose`. Reflected implementation `komorebi_math.expression.model.compose`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(*maps: 'Expression') -> 'Expression'
```

Definition. Compose maps supplied in mathematical outermost-to-innermost order.

Contract (D, C, H, R, X). At least one map is required. A sole factor is type-checked as a linear map and returned unchanged. Two or more factors produce `Compose` in the supplied outermost-to-innermost order. Endpoint mismatches and non-map factors fail closed.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · compose_certificates

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compose_certificates`. Reflected implementation `komorebi_math.expression.certification.compose_certificates`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CERT-FUNCTION`.

Manifest signature (`s`).

```
(certificates: 'Iterable[Certificate]', *, operation: 'str | None' = None, theorem_id: 'str | None' = None,
    ↪ assumptions_checked: 'Iterable[str]' = (), assumptions_unchecked: 'Iterable[str]' = (), diagnostics:
    ↪ 'Mapping[str, Any] | None' = None) -> 'Certificate'
```

Definition. Combine child certificates without strengthening their evidence status, while retaining residuals, assumptions, tolerances, diagnostics, and validity.

Contract (`D, C, H, R, X`). Every child must be a `Certificate`. Residual keys receive deterministic child prefixes, tolerance becomes the largest finite child tolerance, diagnostics are kept in separate child and local namespaces, and assumptions are deduplicated. An assumption marked unchecked anywhere remains unchecked. Validity is the conjunction of child validity, and exactness is the weakest child status, weakened to conditional when unchecked assumptions remain.

Guarantees (`E, P, B, K`). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · `constant_injection`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.constant_injection`. Reflected implementation `komorebi_math.expression.polynomial.constant_injection`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (`s`).

```
(target: 'PolynomialCoordinateSpace') -> 'PolynomialPrimitive'
```

Definition. Construct the exact linear map that embeds a rational scalar as the constant polynomial in a target coordinate space.

Contract (`D, C, H, R, X`). Target must be a polynomial coordinate space. The primitive maps `RATIONAL_SPACE` into the target and takes no rational parameters.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `coordinate_change`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinate_change`. Reflected implementation `komorebi_math.expression.polynomial.coordinate_change`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (`s`).

```
(source: 'PolynomialCoordinateSpace', target: 'PolynomialCoordinateSpace') -> 'PolynomialPrimitive'
```

Definition. Construct the exact basis-change map between equal-degree polynomial spaces over the same physical variable.

Contract (`D, C, H, R, X`). Source and target must be polynomial spaces with the same physical variable and equal degree. Their complete basis witnesses may differ. The returned primitive has no rational parameters.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `derivative`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.derivative`. Reflected implementation `komorebi_math.expression.polynomial.derivative`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (`s`).

```
(source: 'PolynomialCoordinateSpace') -> 'PolynomialPrimitive'
```

Definition. Construct the tight polynomial derivative, using the compatible degree-minus-one target or a zero endomorphism at degree zero.

Contract (`D, C, H, R, X`). Source must be a polynomial coordinate space. For positive degree the target is the exact compatible truncation through degree minus one. At degree zero the result is the zero endomorphism of the same one-dimensional space.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `equivalent`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.equivalent`. Reflected implementation `komorebi_math.expression.engine.equivalent`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(left: 'Expression', right: 'Expression', *, left_bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' =
    ↪ None, right_bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' = None, budget: 'ExpressionBudget |
    ↪ None' = None) -> 'EquivalenceResult'
```

Definition. Decide equality of two closed typed expressions by exact semantic type and entrywise normal-form comparison.

Contract (D, C, H, R, X). Both operands must be expressions. Each is checked independently. Different semantic types return an exact false decision without normal forms. Matching types are normalized and compared entrywise. Open terms require complete bindings, so the function decides the supplied closed instances rather than a universally quantified identity.

Guarantees (E, P, B, K). The result uses exact `Fraction` arithmetic and complete semantic types. Matrix and vector work follows the finite expression structure. Coefficient growth can dominate runtime and memory, and the budget can reject large intermediates. Equality is entrywise and exact. The scope excludes general symbolic algebra, analytic functions, arbitrary callbacks, and infinite-dimensional operators.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `evaluate_expression`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.evaluate_expression`. Reflected implementation `komorebi_math.expression.engine.evaluate_expression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(expression: 'Expression', bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' = None, *, budget:
    ↪ 'ExpressionBudget | None' = None) -> 'ExpressionResult'
```

Definition. Evaluate an expression through both direct normalization and compiled-plan execution, requiring exact agreement between the two paths.

Contract (D, C, H, R, X). Direct normalization, compilation, and plan execution are all performed. The planned and direct exact data and types must agree entrywise. Disagreement raises `ValidationError`. The result retains both paths and their combined certificate.

Guarantees (E, P, B, K). The execution language is closed to five opcodes and uses exact rational operations. Compilation and evaluation include independent replay checks and content digests. Matrix-chain planning is cubic in chain length with quadratic tables. Matrix arithmetic and coefficient growth dominate execution. Plan digests are integrity checks, not signatures or authenticated transport.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `evaluation`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.evaluation`. Reflected implementation `komorebi_math.expression.polynomial.evaluation`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (`s`).

```
(source: 'PolynomialCoordinateSpace', point: 'int | Fraction') -> 'PolynomialPrimitive'
```

Definition. Construct the exact point-evaluation functional from a polynomial coordinate space to the rational scalar space.

Contract (`D, C, H, R, X`). Source must be a polynomial coordinate space. The point is converted to `Fraction`, and the target is `RATIONAL_SPACE`.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `exact_binding`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.exact_binding`. Reflected implementation `komorebi_math.expression.engine.exact_binding`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (`s`).

```
(value: 'Any', declared_type: 'CoordinateSpace | LinearMapType', *, theorem_id: 'str' = 'EXPR.BINDING.EXACT') ->
   ↪ 'ExpressionBinding'
```

Definition. Validate exact rational data against a declared coordinate or map type and wrap it in an unconditional exact binding certificate.

Contract (`D, C, H, R, X`). The declared type is replay-validated. A value for a coordinate space must be a finite exact vector of the declared dimension. A value for a map type must be an exact matrix of target-by-source shape. Only integers and `Fraction` values are accepted. The returned certificate uses the supplied theorem ID and has unconditional exact status.

Guarantees (`E, P, B, K`). The result uses exact `Fraction` arithmetic and complete semantic types. Matrix and vector work follows the finite expression structure. Coefficient growth can dominate runtime and memory, and the budget can reject large intermediates. Equality is entrywise and exact. The scope excludes general symbolic algebra, analytic functions, arbitrary callbacks, and infinite-dimensional operators.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · `exact_internal_certificate`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.exact_internal_certificate`. Reflected implementation `komorebi_math.expression.certification.exact_internal_certificate`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CERT-FUNCTION`.

Manifest signature (s).

```
(operation: 'str', *, theorem_id: 'str | None' = None, assumptions_checked: 'Iterable[str]' = (), diagnostics:
   ↪  'Mapping[str, Any] | None' = None) -> 'Certificate'
```

Definition. Create an exact certificate for a finite internal operation whose correctness is established by construction and replayed checks.

Contract (D, C, H, R, X). `operation` must be a nonempty string. A supplied theorem ID and every checked assumption must also be nonempty. Diagnostics must be a mapping with nonempty string keys. The returned certificate is valid, exact, and records the internal-operation assumption. It does not execute an external theorem prover.

Guarantees (E, P, B, K). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · exact_map

Identity (q, a, t, k). Public research-manifest route `komorebi_math.exact_map`. Reflected implementation `komorebi_math.expression.model.exact_map`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(map_type: 'LinearMapType', matrix: 'Iterable[Iterable[Any]]', *, label: 'str' = '') -> 'ExactMapLiteral'
```

Definition. Normalize an iterable of exact rational rows and construct an `ExactMapLiteral` of the declared shape.

Contract (D, C, H, R, X). Rows and their entries are materialized before delegation to `ExactMapLiteral`. The helper does not infer a map type or resize data. Invalid row structure, rational entries, labels, or shape fail in the literal constructor.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · exact_value

Identity (q, a, t, k). Public research-manifest route `komorebi_math.exact_value`. Reflected implementation `komorebi_math.expression.model.exact_value`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(space: 'CoordinateSpace', entries: 'Iterable[Any]') -> 'ExactValueLiteral'
```

Definition. Normalize an iterable of exact rational entries and construct an `ExactValueLiteral` in the declared space.

Contract (D, C, H, R, X). The iterable is materialized and delegated to `ExactValueLiteral`. Exact scalar conversion and dimension checks occur there. Infinite iterables are outside the contract.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `exactness_strength`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.exactness_strength`. Reflected implementation `komorebi_math.expression.certification.exactness_strength`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CERT-FUNCTION`.

Manifest signature (s).

```
(value: 'Exactness') -> 'int'
```

Definition. Return the total-order rank used to compare `Exactness` evidence statuses, where a larger rank is weaker.

Contract (D, C, H, R, X). The argument must be an `Exactness` member. The fixed ranks are exact 0, numerical 1, conditional 2, heuristic 3, and planned 4. Passing a string or another value raises `TypeError`.

Guarantees (E, P, B, K). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · `execute_plan`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.execute_plan`. Reflected implementation `komorebi_math.expression.engine.execute_plan`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(plan: 'ExpressionPlan', *, budget: 'ExpressionBudget | None' = None) -> 'NormalForm'
```

Definition. Revalidate and execute a self-contained exact expression plan, producing a certified normal form.

Contract (D, C, H, R, X). The input must be exactly `ExpressionPlan`. Constructor validation is replayed, instruction count is budgeted, and the content digest is recomputed. Dependencies must be topological. Each instruction is executed with exact rational operations, checked against its declared type and resource limits, and combined into a final normal form.

Guarantees (E, P, B, K). The execution language is closed to five opcodes and uses exact rational operations. Compilation and evaluation include independent replay checks and content digests. Matrix-chain planning is cubic in chain length with quadratic tables. Matrix arithmetic and coefficient growth dominate execution. Plan digests are integrity checks, not signatures or authenticated transport.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `expression_digest`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.expression_digest`. Reflected implementation `komorebi_math.expression.portable.expression_digest`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-PORTABLE`.

Manifest signature (s).

```
(expression: 'Expression', *, budget: 'ExpressionBudget | None' = None) -> 'str'
```

Definition. Compute the SHA-256 digest of canonical semantic expression JSON, omitting display labels and bound-variable names.

Contract (D, C, H, R, X). Budget preflight runs first. Canonical semantic JSON includes complete type witnesses, exact entries, free-symbol names, node kinds, and primitive parameters. Display labels are omitted and bound symbols use lexical distance. The returned SHA-256 is unkeyed.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · `expression_from_dict`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.expression_from_dict`. Reflected implementation `komorebi_math.expression.portable.expression_from_dict`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-PORTABLE`.

Manifest signature (s).

```
(value: 'Mapping[str, Any]', *, budget: 'ExpressionBudget | None' = None) -> 'Expression'
```

Definition. Validate a versioned expression envelope, reconstruct the exact built-in expression tree, and verify its semantic digest.

Contract (D, C, H, R, X). The mapping must have exactly the four envelope fields and the current schema and version. The strict decoder reconstructs only known built-in types and nodes, applies occurrence and resource limits, reruns expression preflight, recomputes the semantic digest, and compares it with `hmac.compare_digest`.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · `expression_from_json`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.expression_from_json`. Reflected implementation `komorebi_math.expression.portable.expression_from_json`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-PORTABLE`.

Manifest signature (s).

```
(value: 'str | bytes', *, budget: 'ExpressionBudget | None' = None) -> 'Expression'
```

Definition. Parse strict canonical UTF-8 expression JSON with duplicate-key, float, constant, resource, schema, and digest checks.

Contract (D, C, H, R, X). Input must be UTF-8 `str` or `bytes` within the size budget. JSON parsing rejects duplicate keys, floats, nonfinite constants, malformed syntax, and excessive recursion. The original text must exactly equal the canonical re-encoding before dictionary-level schema and digest validation proceeds.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · `expression_to_dict`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.expression_to_dict`. Reflected implementation `komorebi_math.expression.portable.expression_to_dict`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-PORTABLE`.

Manifest signature (s).

```
(expression: 'Expression', *, budget: 'ExpressionBudget | None' = None) -> 'dict[str, Any]'
```

Definition. Encode one expression as a strict versioned dictionary envelope with a semantic SHA-256 digest and symmetric decode-budget validation.

Contract (D, C, H, R, X). The expression is budget-preflighted and encoded as a finite tree with exact field sets and versions. The envelope contains `expression`, `schema`, `schema_version`, and `semantic_sha256`. The produced envelope is then decoded under the same budget so the encoder cannot emit data that its paired decoder rejects.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · expression_to_json

Identity (q, a, t, k). Public research-manifest route `komorebi_math.expression_to_json`. Reflected implementation `komorebi_math.expression.portable.expression_to_json`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-PORTABLE`.

Manifest signature (s).

```
(expression: 'Expression', *, budget: 'ExpressionBudget | None' = None) -> 'str'
```

Definition. Serialize one expression envelope as compact canonical UTF-8 and NFC JSON text.

Contract (D, C, H, R, X). The dictionary envelope is generated first, then encoded with sorted keys, compact separators, NFC text, and no nonfinite values. The byte length must remain within the selected budget.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · finite_difference

Identity (q, a, t, k). Public research-manifest route `komorebi_math.finite_difference`. Reflected implementation `komorebi_math.expression.polynomial.finite_difference`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (s).

```
(source: 'PolynomialCoordinateSpace', step: 'int | Fraction' = 1) -> 'PolynomialPrimitive'
```

Definition. Construct the endomorphism `p(x) -> p(x + step) - p(x)` for a nonzero rational step.

Contract (D, C, H, R, X). Source must be a polynomial coordinate space. Step is converted to `Fraction` and must be nonzero. The declared target remains the original source space even though the image degree can drop.

Guarantees (E, P, B, K). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · identity

Identity (q, a, t, k). Public research-manifest route `komorebi_math.identity`. Reflected implementation `komorebi_math.expression.model.identity`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (`s`).

```
(space: 'CoordinateSpace') -> 'IdentityMap'
```

Definition. Construct the identity-map expression on a supported coordinate space.

Contract (`D, C, H, R, X`). The function delegates to `IdentityMap`. It creates a typed node, not an allocated dense matrix.

Guarantees (`E, P, B, K`). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `interval_integration`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.interval_integration`. Reflected implementation `komorebi_math.expression.polynomial.interval_integration`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-CONSTRUCTOR`.

Manifest signature (`s`).

```
(source: 'PolynomialCoordinateSpace', lower: 'int | Fraction', upper: 'int | Fraction', density: 'int | Fraction' =
    ↪ 1) -> 'PolynomialPrimitive'
```

Definition. Construct the exact density-weighted polynomial integration functional on one closed rational interval.

Contract (`D, C, H, R, X`). Source must be a polynomial coordinate space. Lower, upper, and density are converted to `Fraction`. Lower must not exceed upper and density must be nonnegative. The target is `RATIONAL_SPACE`.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `let`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.let`. Reflected implementation `komorebi_math.expression.model.let`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (`s`).

```
(binding: 'Symbol', value: 'Expression', body: 'Expression') -> 'Let'
```

Definition. Construct a lexical `Let` node after checking that the bound value matches the symbol declaration.

Contract (`D, C, H, R, X`). The function delegates to `Let`. It does not substitute or evaluate the body at construction time. Binder identity and type compatibility are enforced by the node.

Guarantees (`E, P, B, K`). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a

matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `matrix_chain_multiply`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.matrix_chain_multiply`. Reflected implementation `komorebi_math.expression.planning.matrix_chain_multiply`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CHAIN-FUNCTION`.

Manifest signature (s).

```
(matrices: 'Sequence[Iterable[Iterable[Any]]]', plan: 'MatrixChainPlan') -> 'Matrix'
```

Definition. Multiply a finite exact rational matrix chain by replaying a validated optimal matrix-chain plan.

Contract (D, C, H, R, X). The plan is replay-validated. The matrix sequence must have the recorded count. Every matrix is finite, nonempty, rectangular, exact rational, and of the declared shape. The recorded split tree is executed iteratively with exact matrix multiplication, and the final shape is checked.

Guarantees (E, P, B, K). The optimality claim is exact only for order-preserving binary parenthesizations under classical dense scalar-multiplication count. Planning uses `O(n^3)` time and `O(n^2)` table space for `n` matrices. It does not model additions, sparsity, rank, memory traffic, parallelism, GPU launches, Strassen-like algorithms, rounding error, or wall-clock time.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover matrix-chain optimum, tie breaking, exhaustive small-chain comparison, shape validation, exact multiplication, and plan tamper rejection. See Chapters 52 and 68.

C.1B · `matrix_chain_parenthesization`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.matrix_chain_parenthesization`. Reflected implementation `komorebi_math.expression.planning.matrix_chain_parenthesization`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CHAIN-FUNCTION`.

Manifest signature (s).

```
(plan: 'MatrixChainPlan', labels: 'Sequence[str] | None' = None) -> 'str'
```

Definition. Render the deterministic binary tree selected by a validated matrix-chain plan.

Contract (D, C, H, R, X). The plan is fully replay-validated. Optional labels must be a finite sequence with one nonempty NFC-normalized string per matrix. The selected tree is rendered iteratively with `@`. Invalid labels, counts, or plans fail.

Guarantees (E, P, B, K). The optimality claim is exact only for order-preserving binary parenthesizations under classical dense scalar-multiplication count. Planning uses `O(n^3)` time and `O(n^2)` table space for `n` matrices. It does not model additions, sparsity, rank, memory traffic, parallelism, GPU launches, Strassen-like algorithms, rounding error, or wall-clock time.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover matrix-chain optimum, tie breaking, exhaustive small-chain comparison, shape validation, exact multiplication, and plan tamper rejection. See Chapters 52 and 68.

C.1B · matrix_chain_plan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.matrix_chain_plan`. Reflected implementation `komorebi_math.expression.planning.matrix_chain_plan`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CHAIN-FUNCTION`.

Manifest signature (s).

```
(dimensions: 'Sequence[int]') -> 'MatrixChainPlan'
```

Definition. Find the exact minimum classical dense scalar-multiplication cost over all order-preserving binary parenthesizations of a dimension chain.

Contract (D, C, H, R, X). The dimension sequence must contain at least two positive integers and no booleans. The dynamic program examines every order-preserving binary split, choosing the smallest split index on ties. A fixed one-million-candidate guard raises `ResourceLimitError` before excessive planning.

Guarantees (E, P, B, K). The optimality claim is exact only for order-preserving binary parenthesizations under classical dense scalar-multiplication count. Planning uses `O(n^3)` time and `O(n^2)` table space for `n` matrices. It does not model additions, sparsity, rank, memory traffic, parallelism, GPU launches, Strassen-like algorithms, rounding error, or wall-clock time.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover matrix-chain optimum, tie breaking, exhaustive small-chain comparison, shape validation, exact multiplication, and plan tamper rejection. See Chapters 52 and 68.

C.1B · normal_form_digest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.normal_form_digest`. Reflected implementation `komorebi_math.expression.engine.normal_form_digest`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(data: 'ExactData', expression_type: 'Any') -> 'str'
```

Definition. Validate typed exact vector or matrix data and hash its canonical normal-form record.

Contract (D, C, H, R, X). The type is validated, data are converted to the exact vector or matrix required by that type, and canonical rational tokens plus the complete type witness are hashed. Shape and scalar violations raise before hashing. The digest is unkeyed metadata, not authentication.

Guarantees (E, P, B, K). The digest is deterministic for identical exact type and data records. Validation and encoding are linear in exact entries and type-witness size. SHA-256 supplies an integrity identifier but no secrecy, origin authentication, or collision-proof mathematical theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · normalize_expression

Identity (q, a, t, k). Public research-manifest route `komorebi_math.normalize_expression`. Reflected implementation `komorebi_math.expression.engine.normalize_expression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(expression: 'Expression', bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' = None, *, budget:
   ↪  'ExpressionBudget | None' = None) -> 'NormalForm'
```

Definition. Reduce a closed, well-typed finite expression to its unique exact rational vector or matrix normal form.

Contract (D, C, H, R, X). The expression is first checked under the selected budget. Every free symbol must resolve to a compatible binding. Literals, primitives, lexical bindings, sums, scales, compositions, and applications are evaluated with exact rational vector and matrix operations. Intermediate and final data are budget-checked. Missing bindings, type failures, coefficient growth beyond limits, or unsupported nodes raise explicit exceptions.

Guarantees (E, P, B, K). The result uses exact `Fraction` arithmetic and complete semantic types. Matrix and vector work follows the finite expression structure. Coefficient growth can dominate runtime and memory, and the budget can reject large intermediates. Equality is entrywise and exact. The scope excludes general symbolic algebra, analytic functions, arbitrary callbacks, and infinite-dimensional operators.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `primitive_certificate`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.primitive_certificate`. Reflected implementation `komorebi_math.expression.polynomial.primitive_certificate`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-REPLAY`.

Manifest signature (s).

```
(primitive: 'PolynomialPrimitive', *, claimed_matrix: 'Iterable[Iterable[Any]] | None' = None) -> 'Certificate'
```

Definition. Certify exact structural replay of a polynomial primitive and, when supplied, exact equality with a claimed matrix.

Contract (D, C, H, R, X). The argument must be a `PolynomialPrimitive`. Replay is always performed. Without a claim the certificate is valid and exact. With `claimed_matrix`, validity additionally requires exact shape and entrywise equality. The theorem ID is determined by primitive kind and tolerance is zero.

Guarantees (E, P, B, K). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `primitive_matrix_equal`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.primitive_matrix_equal`. Reflected implementation `komorebi_math.expression.polynomial.primitive_matrix_equal`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-REPLAY`.

Manifest signature (`s`).

```
(primitive: 'PolynomialPrimitive', matrix: 'Iterable[Iterable[Any]]') -> 'bool'
```

Definition. Validate a claimed exact rational matrix and compare it entrywise with a freshly replayed polynomial primitive.

Contract (`D, C, H, R, X`). The claimed rows are materialized and converted only from integers or `Fraction`. Ragged or invalid data raise. A shape mismatch returns `False`. Otherwise exact tuple equality is compared with a fresh replay.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `replay`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.replay`. Reflected implementation `komorebi_math.expression.polynomial.replay`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-REPLAY`.

Manifest signature (`s`).

```
(primitive: 'PolynomialPrimitive') -> 'Matrix'
```

Definition. Recompute the exact rational matrix of a polynomial primitive solely from its basis witnesses, kind, map type, and parameters.

Contract (`D, C, H, R, X`). The argument must be a `PolynomialPrimitive`. The matrix is recomputed from exact basis matrices and rational parameters for the recorded kind. No callback, cached matrix, display label, or claimed result is trusted. Unsupported or malformed primitives fail closed.

Guarantees (`E, P, B, K`). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (`V, L`). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `replay_matrix`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.replay_matrix`. Reflected implementation `komorebi_math.expression.polynomial.replay`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-POLY-REPLAY`.

Manifest signature (s).

```
(primitive: 'PolynomialPrimitive') -> 'Matrix'
```

Definition. The public name-preserving alias of `replay` for recomputing a polynomial primitive matrix.

Contract (D, C, H, R, X). The argument must be a `PolynomialPrimitive`. The matrix is recomputed from exact basis matrices and rational parameters for the recorded kind. No callback, cached matrix, display label, or claimed result is trusted. Unsupported or malformed primitives fail closed.

Guarantees (E, P, B, K). Every accepted primitive has an exact rational matrix determined by finite basis witnesses and parameters. Replay is deterministic and backend-neutral. Basis inversion and operator conversion use dense exact matrix algebra, typically cubic in coordinate dimension before operation-specific work. The certificate covers the finite polynomial map only, not a general analytic theorem.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover the Fibonacci-Euler pipeline, basis spoof resistance, all nine primitive kinds, exact replay, coordinate naturality, the basepoint defect, density-aware FTC, and degree-zero differentiation. See Chapters 50, 51, and 68.

C.1B · `scale`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.scale`. Reflected implementation `komorebi_math.expression.model.scale`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(scalar: 'int | Fraction', value: 'Expression') -> 'Scale'
```

Definition. Convert an integer or `Fraction` coefficient and construct a typed `Scale` node.

Contract (D, C, H, R, X). The coefficient is converted to an exact `Fraction` and passed to `Scale`. Booleans, floats, and non-expression values are rejected.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `simplify_expression`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.simplify_expression`. Reflected implementation `komorebi_math.expression.engine.simplify_expression`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-ENGINE-FUNCTION`.

Manifest signature (s).

```
(expression: 'Expression', bindings: 'Mapping[str | Symbol, ExpressionBinding] | None' = None, *, budget:
   ↪ 'ExpressionBudget | None' = None) -> 'SimplificationResult'
```

Definition. Apply the finite conservative rewrite system and certify every accepted step by exact before-and-after normalization.

Contract (D, C, H, R, X). The source is normalized first. The restricted rewrite system handles identities, zeros, scale and sum flattening, literal application, coordinate cocycles and transports, derivative-antiderivative laws, the basepoint

defect, and the finite polynomial FTC. Every proposed step is accepted only after exact before-and-after normal forms agree. A 256-step local convergence guard and the global budget prevent unbounded rewriting.

Guarantees (E, P, B, K). The result uses exact `Fraction` arithmetic and complete semantic types. Matrix and vector work follows the finite expression structure. Coefficient growth can dominate runtime and memory, and the budget can reject large intermediates. Equality is entrywise and exact. The scope excludes general symbolic algebra, analytic functions, arbitrary callbacks, and infinite-dimensional operators.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover structural checking, free bindings, exact normalization, true and false equality decisions, conservative rewrites, dual-path evaluation, plan replay, and tamper rejection. See Chapters 50 through 52 and Chapter 68.

C.1B · `symbol`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.symbol`. Reflected implementation `komorebi_math.expression.model.symbol`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(name: 'str', declared_type: 'ExpressionType') -> 'Symbol'
```

Definition. Construct an identity-distinct typed `Symbol` with an NFC-normalized nonempty name.

Contract (D, C, H, R, X). The function delegates to `Symbol` and returns a fresh identity-distinct object on every call, even when name and type are equal.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · `then`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.then`. Reflected implementation `komorebi_math.expression.model.then`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(*maps: 'Expression') -> 'Expression'
```

Definition. Compose maps in the order in which they act, reversing them before delegating to `compose`.

Contract (D, C, H, R, X). At least one map is required. Inputs are interpreted in action order, reversed, and passed to `compose`. Thus `then(A, B)` represents `B` after `A`.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_`

example.py cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1B · type_from_dict

Identity (q, a, t, k). Public research-manifest route komorebi_math.type_from_dict. Reflected implementation komorebi_math.expression.portable.type_from_dict. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by [RESEARCH] policy pre-beta-additive. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind function. Profile C1-EXPR-PORTABLE.

Manifest signature (s).

```
(value: 'Mapping[str, Any]', *, budget: 'ExpressionBudget | None' = None) -> 'ExpressionType'
```

Definition. Reconstruct one exact expression type from its strict, versioned transport record under a resource budget.

Contract (D, C, H, R, X). The input mapping is validated recursively under the selected budget. Exact field sets, versions, strings, integers, rational witnesses, and supported type kinds are required. Unknown or extra fields fail closed.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, tests/test_block20_expression_calculus.py, verification/block20_math_verifier.py, and examples/block20_typed_expression_worked_example.py cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · type_to_dict

Identity (q, a, t, k). Public research-manifest route komorebi_math.type_to_dict. Reflected implementation komorebi_math.expression.portable.type_to_dict. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by [RESEARCH] policy pre-beta-additive. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind function. Profile C1-EXPR-PORTABLE.

Manifest signature (s).

```
(expression_type: 'ExpressionType', *, budget: 'ExpressionBudget | None' = None) -> 'dict[str, Any]'
```

Definition. Encode one exact expression type as a strict transport dictionary and replay the decoder against that record.

Contract (D, C, H, R, X). A default or exact ExpressionBudget is selected. The supported type is encoded with explicit kind and version fields, the JSON tree and encoded size are checked, and the decoder is replayed before the dictionary is returned.

Guarantees (E, P, B, K). Encoding and decoding are deterministic for the supported finite grammar and selected budget. Work is linear in the serialized tree and exact witness size, aside from SHA-256 and expression preflight. Shared DAG nodes may appear once per occurrence in the portable tree. The decoder never imports payload-named classes, evaluates source, invokes callbacks, or unpickles data. The checksum detects inconsistent content only when the recorded digest is held fixed and does not authenticate the producer.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, tests/test_block20_expression_calculus.py, verification/block20_math_verifier.py, and examples/block20_typed_expression_worked_example.py cover all type and node roundtrips, canonical text, alpha equivalence, duplicate keys, floats, schema and digest tampering, dangling binders, cycles, and resource limits. See Chapters 50, 52, and 68.

C.1B · weakest_exactness

Identity (q, a, t, k). Public research-manifest route `komorebi_math.weakest_exactness`. Reflected implementation `komorebi_math.expression.certification.weakest_exactness`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CERT-FUNCTION`.

Manifest signature (s).

```
(*values: 'Exactness') -> 'Exactness'
```

Definition. Return the weakest supplied evidence status, with `EXACT` as the empty meet.

Contract (D, C, H, R, X). With no arguments the function returns `Exactness.EXACT`. Otherwise every argument must be an `Exactness` member, and the one with the largest weakness rank is returned.

Guarantees (E, P, B, K). Evidence status is never promoted above the weakest child claim. Composition is deterministic and linear in child certificates, residual fields, assumptions, and diagnostics. Certificates remain finite records. They do not authenticate the caller, prove an unchecked assumption, or replace independent theorem verification.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover binding-shape replay, exactness weakening, unchecked-assumption propagation, normal-form evidence, and rewrite certificates. See Chapters 51 and 52.

C.1B · zero_map

Identity (q, a, t, k). Public research-manifest route `komorebi_math.zero_map`. Reflected implementation `komorebi_math.expression.model.zero_map`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It is not part of the frozen stable or curated beta compatibility promise. Manifest kind `function`. Profile `C1-EXPR-CONSTRUCTOR`.

Manifest signature (s).

```
(map_type: 'LinearMapType') -> 'ZeroMap'
```

Definition. Construct the exact zero-map expression for a declared `LinearMapType`.

Contract (D, C, H, R, X). The function delegates to `ZeroMap`. It creates a typed node, not an allocated dense matrix.

Guarantees (E, P, B, K). Formation checks are exact and local. Accepted numeric data are rational, and accepted endpoints use complete semantic type equality. Construction does not claim denotational equality or execute a matrix operation. Those claims arise only from checking, normalization, or replay. Cost is linear in materialized literal data or child count, otherwise constant.

Evidence and links (V, L). The committed research manifest, runtime reflection audit, `tests/test_block20_expression_calculus.py`, `verification/block20_math_verifier.py`, and `examples/block20_typed_expression_worked_example.py` cover type formation, basis witnesses, lexical scope, local node validation, cycle rejection, and every resource-budget dimension. See Chapters 50 and 68.

C.1C Coordinate systems, transforms, realizations, and frame algebra: 53 entries

This section documents the complete root-exported surface owned by the `komorebi_math.coordinates` implementation family. It covers finite bases and exact coordinate maps, affine and formal changes, finite-field and tensor transport, recurrence and state-space realizations, polynomial connections, numerical and exact analysis and synthesis systems, coefficient gauges, operator transport, resource guards, and portable coordinate persistence. Exact rational contracts and tolerance-based NumPy contracts are stated separately. A numerical certificate records a finite residual test. It does not convert that test into an exact identity.

C.1C · AffineCoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AffineCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.affine.AffineCoordinateTransform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-AFFINE`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Matrix', offset: 'Vector', theorem: 'str' = 'CC.F1', description: 'str' =
   ↪  '') -> None
```

Definition. An exact affine map `y=A x+b` between equal-dimensional spaces.

Contract (D, C, H, R, X). Construction requires a square invertible exact matrix, a matching offset, and nonempty endpoint names. Application, composition, inversion, and homogeneous lifting preserve exact rational arithmetic and reject incompatible dimensions or endpoints. Principal public operations are `apply`, `certificate`, `dimension`, `homogeneous_matrix`, `inverse`, `invertible`, `then`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_affine_formal.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · AnalysisSynthesisBlocks

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AnalysisSynthesisBlocks`. Reflected implementation `komorebi_math.coordinates.analysis_synthesis.AnalysisSynthesisBlocks`. The same object is available through the curated stable routes `komorebi_math.stable.AnalysisSynthesisBlocks`, `komorebi_math.v1.AnalysisSynthesisBlocks`, and `komorebi_math.api.v1.AnalysisSynthesisBlocks`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-ANALYSIS-SYNTHESIS`.

Manifest signature (s).

```
(system: "'AnalysisSynthesisSystem'", groups: 'tuple[tuple[int, ...], ...]', blocks: 'tuple[tuple[np.ndarray,
   ↪  ...], ...]', operator: 'np.ndarray') -> None
```

Definition. Packet blocks of one operator under a declared analysis and synthesis atlas.

Contract (D, C, H, R, X). The groups must form valid coefficient packets for the supplied system. Every block and the represented operator must have source-space shape. `reconstruct` sums the blocks and `certificate` compares the reconstruction residual with the system tolerance. Principal public operations are `certificate`, `reconstruct`.

Guarantees (E, P, B, K). The implementation uses finite NumPy arithmetic. Residuals, rank, condition numbers, and gauge equivalence are tolerance-based evidence, not exact identities. Dense factorizations and matrix products can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block16_analysis_synthesis.py` and `examples/block16_analysis_synthesis.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · AnalysisSynthesisCoefficientBlocks

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AnalysisSynthesisCoefficientBlocks`. Reflected implementation `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisCoefficientBlocks`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FRAME-ALGEBRA`.

Manifest signature (s).

```
(mapping: 'AnalysisSynthesisMap', source_partition: 'CoefficientPartition', target_partition:
    ↪ 'CoefficientPartition') -> None
```

Definition. Small target-by-source blocks derived from a coefficient lift.

Contract (D, C, H, R, X). Domain and codomain partitions must match the coefficient dimensions of the supplied map. Block lookup and reblocking validate indices and endpoints. Assembly and composition operate through the canonical coefficient lift. Principal public operations are `assemble`, `certificate`, `physical_block`, `reblock`, `then`.

Guarantees (E, P, B, K). Exact variants use rational arithmetic. Numerical variants use finite NumPy arithmetic at an explicit tolerance. Dense lifts, pseudoinverses, projections, direct sums, tensor products, and block assembly can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · AnalysisSynthesisGauge

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AnalysisSynthesisGauge`. Reflected implementation `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisGauge`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FRAME-ALGEBRA`.

Manifest signature (s).

```
(system: 'AnalysisSynthesisSystem') -> None
```

Definition. Gauge and quotient calculus for one numerical presentation.

Contract (D, C, H, R, X). The constructor accepts one numerical analysis and synthesis system. Its methods split coefficients into canonical and gauge parts, evaluate quotient metrics, and test gauge equivalence at the system tolerance. Principal public operations are `analysis`, `canonical_coefficients`, `certificate`, `coefficient_metric`, `coefficient_projection`, `coefficient_seminorm`, `coordinate_dimension`, `coordinates`, `direct_sum`, `dual`, `gauge_equivalent`, `gauge_part`, and related accessors.

Guarantees (E, P, B, K). Exact variants use rational arithmetic. Numerical variants use finite NumPy arithmetic at an explicit tolerance. Dense lifts, pseudoinverses, projections, direct sums, tensor products, and block assembly can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · AnalysisSynthesisMap

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AnalysisSynthesisMap`. Reflected implementation `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FRAME-ALGEBRA`.

Manifest signature (s).

```
(domain: 'AnalysisSynthesisSystem', codomain: 'AnalysisSynthesisSystem', operator: 'np.ndarray', theorem: 'str' =
    ↪ 'KM-AS-MAP-01') -> None
```

Definition. A physical linear map and its canonical coefficient lift.

Contract (D, C, H, R, X). Domain and codomain presentations must have compatible physical dimensions, and the operator must map between their source spaces. Coefficient lifts, composition, adjoints, bridges, and blocks preserve declared endpoints and validate shapes. Principal public operations are `add`, `adjoint`, `apply_coefficients`, `apply_source`, `blocks`, `certificate`, `coefficient_lift`, `compose`, `dual_adjoint`, `reconstruct`, `scaled`, `then`, and related accessors.

Guarantees (E, P, B, K). Exact variants use rational arithmetic. Numerical variants use finite NumPy arithmetic at an explicit tolerance. Dense lifts, pseudoinverses, projections, direct sums, tensor products, and block assembly can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · AnalysisSynthesisSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AnalysisSynthesisSystem`. Reflected implementation `komorebi_math.coordinates.analysis_synthesis.AnalysisSynthesisSystem`. The same object is available through the curated stable routes `komorebi_math.stable.AnalysisSynthesisSystem`, `komorebi_math.v1.AnalysisSynthesisSystem`, and `komorebi_math.api.v1.AnalysisSynthesisSystem`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-ANALYSIS-SYNTHESIS`.

Manifest signature (s).

```
(analysis: 'np.ndarray', synthesis: 'np.ndarray', source: 'str' = 'source', coordinates: 'str' = 'coordinates',
    ↪ tolerance: 'float' = 1e-12, theorem: 'str' = 'KM-AS-01') -> None
```

Definition. A finite analysis map `A` and synthesis map `S` with `S A = I`.

Contract (D, C, H, R, X). Analysis and synthesis must have transposed rectangular shapes, names must be nonempty, and tolerance must be positive and finite. Direct construction records a candidate pair. `certificate` checks rank and the residual of `S A - I`, while `canonical_dual` and `from_invertible` construct and require valid systems. Principal public operations are `analyze`, `certificate`, `component`, `components`, `coordinate_dimension`, `frame_operator`, `operator_blocks`, `projector`, `projectors`, `reconstruct`, `reconstruction_certificate`, `redundant`, and related accessors.

Guarantees (E, P, B, K). The implementation uses finite NumPy arithmetic. Residuals, rank, condition numbers, and gauge equivalence are tolerance-based evidence, not exact identities. Dense factorizations and matrix products can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block16_analysis_synthesis.py` and `examples/block16_analysis_synthesis.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · BezoutDefectIdentity

Identity (q, a, t, k). Public research-manifest route `komorebi_math.BezoutDefectIdentity`. Reflected implementation `komorebi_math.coordinates.operators.BezoutDefectIdentity`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-OPERATORS`.

Manifest signature (s).

```
(gcd: 'Vector', left_multiplier: 'Vector', right_multiplier: 'Vector', reconstructed: 'Vector', expected:
   ↪  'Vector', valid: 'bool') -> None
```

Definition. A finite prefix reconstruction from two coprime defect streams.

Contract (D, C, H, R, X). The frozen record stores the gcd polynomial, Bezout multipliers, reconstructed prefix, expected prefix, and validity flag. Direct construction does not recompute the algebra. `bezout_defect_identity` is the authoritative constructor and `certificate` reports the finite exact identity. Principal public operations are `certificate`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_operators.py` covers the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 10, 18, and 64.

C.1C · CoefficientPartition

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CoefficientPartition`. Reflected implementation `komorebi_math.coordinates.frame_algebra.CoefficientPartition`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FRAME-ALGEBRA`.

Manifest signature (s).

```
(dimension: 'int', groups: 'tuple[tuple[int, ...], ...]') -> None
```

Definition. A strict ordered partition of finite coefficient indices.

Contract (D, C, H, R, X). Numerical records require compatible finite arrays and tolerances. Exact records require compatible rational matrices. Direct record construction stores the declared data, while certificate and factory routes provide the authoritative reconstruction, lift, gauge, or block checks. Principal public operations are `coarsens`, `refines`.

Guarantees (E, P, B, K). Exact variants use rational arithmetic. Numerical variants use finite NumPy arithmetic at an explicit tolerance. Dense lifts, pseudoinverses, projections, direct sums, tensor products, and block assembly can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · CoordinateAtlas

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CoordinateAtlas`. Reflected implementation `komorebi_math.coordinates.basis.CoordinateAtlas`. The same object is available through the curated stable routes `komorebi_math.stable.CoordinateAtlas`, `komorebi_math.v1.CoordinateAtlas`, and `komorebi_math.api.v1.CoordinateAtlas`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-BASIS`.

Manifest signature (s).

```
(name: 'str' = 'coordinate atlas') -> None
```

Definition. A graph of exact coordinate systems and composable transforms.

Contract (D, C, H, R, X). Systems or bases must be registered before edges are added. Edge dimensions and endpoint names must agree. `resolve` searches the finite graph and composes a compatible path, while conflicting edges, missing routes, or noncommuting path comparisons are reported explicitly. Principal public operations are `compare_paths`, `compose_path`, `direct_transform`, `register_basis`, `register_system`, `register_transform`, `resolve`, `systems`, `transforms`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_basis.py`, `examples/general_coordinate_atlas.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · CoordinateBudget

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CoordinateBudget`. Reflected implementation `komorebi_math.coordinates.budget.CoordinateBudget`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-BUDGET`.

Manifest signature (s).

```
(maximum_matrix_dimension: 'int' = 512, maximum_polynomial_degree: 'int' = 512, maximum_horizon: 'int' = 4096,
    ↪ maximum_exact_entries: 'int' = 1000000) -> None
```

Definition. Finite limits applied before coordinate matrices are materialized.

Contract (D, C, H, R, X). Every limit must be a positive integer. Guard methods reject negative requests as invalid and reject requests above the configured bound before materialization. Principal public operations are `require_degree`, `require_horizon`, `require_matrix`.

Guarantees (E, P, B, K). Checks are deterministic and constant-time in the requested dimensions. Passing a guard does not predict wall-clock time or prove that every permitted computation fits every host.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused coordinate suite and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · CoordinateSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CoordinateSystem`. Reflected implementation `komorebi_math.coordinates.basis.CoordinateSystem`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-BASIS`.

Manifest signature (s).

```
(name: 'str', dimension: 'int', kind: 'str' = 'exact', description: 'str' = '') -> None
```

Definition. Metadata for one finite exact coordinate system.

Contract (D, C, H, R, X). The name must contain nonwhitespace text and the dimension must be positive. Kind and description are metadata. The record does not by itself establish a basis or transform.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_basis.py`, `examples/general_coordinate_atlas.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · CoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CoordinateTransform`. Reflected implementation `komorebi_math.coordinates.transform.CoordinateTransform`. The same object is available through the curated stable routes `komorebi_math.stable.CoordinateTransform`, `komorebi_math.v1.CoordinateTransform`, and `komorebi_math.api.v1.CoordinateTransform`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-TRANSFORM`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Matrix', theorem: 'str', description: 'str' = '') -> None
```

Definition. An exact matrix that maps source coordinates to target coordinates.

Contract (D, C, H, R, X). Endpoint names must be nonempty and the exact matrix nonempty. Application and composition require dimension and endpoint compatibility. Inversion requires a square nonsingular matrix. Principal public operations are `apply`, `certificate`, `determinant`, `inverse`, `roundtrip_valid`, `source_dimension`, `square`, `target_dimension`, `then`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · ExactAnalysisSynthesisMap

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactAnalysisSynthesisMap`. Reflected implementation `komorebi_math.coordinates.frame_algebra.ExactAnalysisSynthesisMap`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FRAME-ALGEBRA`.

Manifest signature (s).

```
(domain: 'ExactAnalysisSynthesisSystem', codomain: 'ExactAnalysisSynthesisSystem', operator: 'Matrix', theorem:
   ↪  'str' = 'KM-AS-EXACT-MAP-01') -> None
```

Definition. An exact rational physical map and coefficient lift.

Contract (D, C, H, R, X). The exact operator must map between compatible physical source spaces. Its coefficient lift, reconstruction, composition, adjoint, addition, scaling, and blocks are exact and endpoint-checked. Principal public operations are `add`, `adjoint`, `apply_coefficients`, `blocks`, `certificate`, `coefficient_lift`, `compose`, `dual_adjoint`, `reconstruct`, `scaled`, `then`.

Guarantees (E, P, B, K). Exact variants use rational arithmetic. Numerical variants use finite NumPy arithmetic at an explicit tolerance. Dense lifts, pseudoinverses, projections, direct sums, tensor products, and block assembly can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · ExactAnalysisSynthesisSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactAnalysisSynthesisSystem`. Reflected implementation `komorebi_math.coordinates.frame_algebra.ExactAnalysisSynthesisSystem`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FRAME-ALGEBRA`.

Manifest signature (s).

```
(analysis: 'Matrix', synthesis: 'Matrix', source: 'str' = 'source', coordinates: 'str' = 'coordinates', theorem:
   ↪  'str' = 'KM-AS-EXACT-01') -> None
```

Definition. An exact rational analysis and synthesis presentation.

Contract (D, C, H, R, X). The exact matrices must have transposed rectangular shapes and satisfy the left-inverse law through the certificate or authoritative constructors. Gauge, dual, transition, direct-sum, and tensor-product operations use exact rational arithmetic. Principal public operations are `analyze`, `canonical_coefficients`, `certificate`, `coefficient_metric`, `coefficient_projection`, `coefficient_seminorm_squared`, `coordinate_dimension`, `direct_sum`, `dual`, `frame_operator`, `gauge_equivalent`, `gauge_part`, and related accessors.

Guarantees (E, P, B, K). Exact variants use rational arithmetic. Numerical variants use finite NumPy arithmetic at an explicit tolerance. Dense lifts, pseudoinverses, projections, direct sums, tensor products, and block assembly can require cubic time and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 20, 48, and 64.

C.1C · FiniteBasis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteBasis`. Reflected implementation `komorebi_math.coordinates.basis.FiniteBasis`. The same object is available through the curated stable routes `komorebi_math.stable.FiniteBasis`, `komorebi_math.v1.FiniteBasis`, and `komorebi_math.api.v1.FiniteBasis`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-BASIS`.

Manifest signature (s).

```
(name: 'str', vectors: 'tuple[Vector, ...]', labels: 'tuple[str, ...]' = (), description: 'str' = '') -> None
```

Definition. A linearly independent finite basis inside a rational ambient space.

Contract (D, C, H, R, X). Basis vectors are stored as columns, must share an ambient dimension, and must be linearly independent. Rectangular bases are permitted. Analysis requires membership in the spanned subspace, while synthesis, connections, dual rows, Gram matrices, and projectors use exact arithmetic. Principal public operations are `ambient_dimension`, `analyze`, `certificate`, `connection_to`, `contains`, `dimension`, `dual_rows`, `gram_matrix`, `matrix`, `orthogonal_projector`, `square`, `synthesize`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_basis.py`, `examples/general_coordinate_atlas.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · FiniteFieldCoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteFieldCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.modular.FiniteFieldCoordinateTransform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-MODULAR`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'ModularMatrix', prime: 'int', theorem: 'str' = 'CC.M1', description: 'str'
    ↪  = '') -> None
```

Definition. An exact linear coordinate transform over `F_prime`.

Contract (D, C, H, R, X). The modulus must be prime, matrix entries are reduced into the finite field, and the square matrix must be invertible modulo that prime. Application, inverse, and composition reject incompatible dimensions or endpoints. Principal public operations are `apply`, `certificate`, `inverse`, `source_dimension`, `square`, `target_dimension`, `then`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_tensor_modular.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 13, 16, and 64.

C.1C · FormalCoordinateChange

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FormalCoordinateChange`. Reflected implementation `komorebi_math.coordinates.formal.FormalCoordinateChange`. The same object is available through the curated stable routes `komorebi_math.stable.FormalCoordinateChange`, `komorebi_math.v1.FormalCoordinateChange`, and `komorebi_math.api.v1.FormalCoordinateChange`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-FORMAL`.

Manifest signature (s).

```
(name: 'str', coefficients: 'Vector', source: 'str' = 'source formal coordinate', target: 'str' = 'target formal
   ↪ coordinate') -> None
```

Definition. A finite exact jet `phi(z)=a_1 z+a_2 z^2+...`.

Contract (D, C, H, R, X). The constant coefficient must vanish and the linear coefficient must be nonzero. Composition, inversion, truncation, and coefficient pushforward or pullback are performed modulo the first omitted power. Principal public operations are `certificate`, `compose`, `degree`, `inverse`, `linear_coefficient`, `pullback_coefficients`, `pushforward_coefficients`, `substitution_transform`, `truncate`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_affine_formal.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · IntertwinerSpace

Identity (q, a, t, k). Public research-manifest route `komorebi_math.IntertwinerSpace`. Reflected implementation `komorebi_math.coordinates.realization.IntertwinerSpace`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-REALIZATION`.

Manifest signature (s).

```
(source_dimension: 'int', target_dimension: 'int', basis: 'tuple[Matrix, ...]') -> None
```

Definition. Solutions of `B S=S A` from a source to a target realization.

Contract (D, C, H, R, X). The record stores source and target dimensions and a tuple of exact basis matrices. Direct construction does not validate the displayed basis. `certificate` checks matrix shapes and the equations `B S = S A`, and `intertwiner_space` is the authoritative solver route. Principal public operations are `certificate`, `contains_invertible_basis_element`, `dimension`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_realization.py`, `examples/recurrence_state_coordinate_atlas.py`, and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18, 31, and 64.

C.1C · LinearRealization

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LinearRealization`. Reflected implementation `komorebi_math.coordinates.realization.LinearRealization`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-REALIZATION`.

Manifest signature (s).

```
(transition: 'Matrix', initial: 'Vector', output: 'Vector', name: 'str' = 'linear realization') -> None
```

Definition. A scalar sequence realization `a_n=h^T A^n v`.

Contract (D, C, H, R, X). Matrices and vectors must have compatible exact dimensions. Observability and recovery are finite-horizon statements. Intertwiner solvers compute exact nullspaces, while record certificates verify displayed basis elements against the intertwining equation. Principal public operations are `dimension`, `prefix`, `state`, `term`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_realization.py`, `examples/recurrence_state_coordinate_atlas.py`, and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18, 31, and 64.

C.1C · NumericCoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.NumericCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.numeric.NumericCoordinateTransform`. The same object is available through the curated stable routes `komorebi_math.stable.NumericCoordinateTransform`, `komorebi_math.v1.NumericCoordinateTransform`, and `komorebi_math.api.v1.NumericCoordinateTransform`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C1-COORD-NUMERIC`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'np.ndarray', theorem: 'str' = 'CC.NM1', description: 'str' = '', tolerance:
    ↪  'float' = 1e-12) -> None
```

Definition. A finite numerical matrix between coordinate systems.

Contract (D, C, H, R, X). The input is a finite two-dimensional NumPy matrix with nonempty endpoint names and a positive finite tolerance. Inversion requires a square nonsingular matrix. Composition and certificates use tolerance-based numerical tests. Principal public operations are `apply`, `certificate`, `condition_number`, `inverse`, `source_dimension`, `square`, `target_dimension`, `then`.

Guarantees (E, P, B, K). The implementation uses finite NumPy arithmetic and reports tolerance-based residual evidence. Dense inversion or condition estimation can require cubic time and quadratic storage. No GPU or network backend is selected implicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 16, 32, and 64.

C.1C · PolynomialCoordinateOperator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolynomialCoordinateOperator`. Reflected implementation `komorebi_math.coordinates.calculus.PolynomialCoordinateOperator`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-CALCULUS`.

Manifest signature (s).

```
(name: 'str', source_family: 'str', target_family: 'str', source_degree: 'int', target_degree: 'int', matrix:
   ↪  'Matrix', theorem: 'str' = 'CC.O1') -> None
```

Definition. A finite polynomial operator matrix between graded family truncations.

Contract (D, C, H, R, X). The matrix shape must match the declared source and target degree truncations. Application and composition require compatible polynomial-family endpoints and use exact finite coefficient arithmetic. Principal public operations are `apply`, `certificate`, `compose`, `square`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_calculus.py` and `examples/coordinate_calculus.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · PolynomialFamily

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolynomialFamily`. Reflected implementation `komorebi_math.coordinates.polynomials.PolynomialFamily`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-POLYNOMIALS`.

Manifest signature (s).

```
(name: 'str', rule: 'Callable[[int], Polynomial]') -> None
```

Definition. A graded polynomial basis with one nonzero leading term per degree.

Contract (D, C, H, R, X). The rule must produce one exact polynomial for each nonnegative degree with a nonzero leading coefficient. `polynomial` and `coefficient_matrix` materialize only the requested finite truncation. Principal public operations are `coefficient_matrix`, `polynomial`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_polynomials.py` and `examples/euler_to_fibonacci_coordinates.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · RecurrenceCoordinateRecord

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RecurrenceCoordinateRecord`. Reflected implementation `komorebi_math.coordinates.recurrence.RecurrenceCoordinateRecord`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-RECURRENCE`.

Manifest signature (s).

```
(name: 'str', coefficients: 'Vector', initial: 'Vector', defects: 'Vector') -> None
```

Definition. Initial state and forcing coordinates for one recurrence model.

Contract (D, C, H, R, X). The coefficient order and initial-state length must agree, and defects provide one forcing coordinate per later prefix value. Reconstruction, homogeneous propagation, conversion to `LinearRecurrence`, and the certificate all refer to that finite prefix. Principal public operations are `as_linear_recurrence`, `certificate`, `coordinates`, `homogeneous`, `length`, `order`, `reconstruct`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_recurrence.py`, `examples/euler_to_fibonacci_coordinates.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · RecurrenceModel

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RecurrenceModel`. Reflected implementation `komorebi_math.coordinates.families.RecurrenceModel`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-FAMILIES`.

Manifest signature (s).

```
(name: 'str', coefficients: 'Vector', initial_values: 'Vector' = (), description: 'str' = '') -> None
```

Definition. A named constant-coefficient recurrence and optional initial state.

Contract (D, C, H, R, X). Coefficients must define positive order, the name must be nonempty, and optional initial values are either absent or have exactly that order. Synthesis requires a complete initial state. Sequence counts and finite transport lengths must be nonnegative. Principal public operations are `analyze`, `companion`, `coordinate_transform_to`, `homogeneous_basis`, `order`, `sequence`, `synthesize`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_families_state.py` and `examples/recurrence_state_coordinate_atlas.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · ShiftPolynomial

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ShiftPolynomial`. Reflected implementation `komorebi_math.coordinates.operators.ShiftPolynomial`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-OPERATORS`.

Manifest signature (s).

```
(coefficients: 'Iterable[Scalar]', name: 'str' = 'shift polynomial') -> 'None'
```

Definition. A polynomial `q(L)` in the canonical coefficient shift operator.

Contract (D, C, H, R, X). Coefficients are normalized to an exact finite polynomial in the canonical shift. Application requires enough input for the declared degree, and multiplication uses exact convolution. Principal public operations are `apply`, `degree`, `multiply`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_operators.py` covers the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 10, 18, and 64.

C.1C · StateRecovery

Identity (q, a, t, k). Public research-manifest route `komorebi_math.StateRecovery`. Reflected implementation `komorebi_math.coordinates.realization.StateRecovery`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-REALIZATION`.

Manifest signature (s).

```
(exact: 'bool', unique: 'bool', rank: 'int', horizon: 'int', state: 'Vector | None', predicted: 'Vector', residual:
    ↪ 'Vector') -> None
```

Definition. The result of state recovery over a finite horizon.

Contract (D, C, H, R, X). The record stores rank, horizon, predicted prefix, residual, and an optional recovered state. Direct construction stores fields. `recover_initial_state` is the authoritative computation and `certificate` checks the finite reconstruction statement. Principal public operations are `certificate`.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_realization.py`, `examples/recurrence_state_coordinate_atlas.py`, and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18, 31, and 64.

C.1C · `StateSpaceModel`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.StateSpaceModel`. Reflected implementation `komorebi_math.coordinates.state_space.StateSpaceModel`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `class`. Profile `C1-COORD-STATE-SPACE`.

Manifest signature (`s`).

```
(name: 'str', transition: 'Matrix', input_matrix: 'Matrix', output_matrix: 'Matrix', feedthrough: 'Matrix') -> None
```

Definition. A finite exact state-space model `x'=Ax+Bu, y=Cx+Du`.

Contract (`D, C, H, R, X`). The transition matrix is square. Input, output, and feedthrough shapes must match the state, input, and output dimensions. Coordinate changes require an invertible state transform. Markov and transfer comparisons are finite-horizon exact statements. Principal public operations are `change_coordinates`, `input_dimension`, `markov_parameter`, `output_dimension`, `state_dimension`, `transfer_equivalent`.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_families_state.py` and `examples/recurrence_state_coordinate_atlas.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · `analyze_recurrence_coordinates`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.analyze_recurrence_coordinates`. Reflected implementation `komorebi_math.coordinates.recurrence.analyze_recurrence_coordinates`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-RECURRENCE`.

Manifest signature (`s`).

```
(values: 'Sequence[Scalar]', coefficients: 'RecurrenceLike', *, name: 'str' = 'recurrence') ->
    ↪ 'RecurrenceCoordinateRecord'
```

Definition. Analyze a finite sequence prefix in recurrence defect coordinates.

Contract (`D, C, H, R, X`). The recurrence coefficient vector must have positive order and the prefix must contain enough values for the requested analysis. Defect coordinates, companion evolution, inter-model transforms, and variation of constants use exact finite arithmetic.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_recurrence.py`, `examples/euler_to_fibonacci_coordinates.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · basis_from_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.basis_from_matrix`. Reflected implementation `komorebi_math.coordinates.basis.basis_from_matrix`. The same object is available through the curated stable routes `komorebi_math.stable.basis_from_matrix`, `komorebi_math.v1.basis_from_matrix`, and `komorebi_math.api.v1.basis_from_matrix`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C1-COORD-BASIS`.

Manifest signature (s).

```
(name: 'str', matrix: 'Iterable[Iterable[Scalar]]', *, labels: 'Sequence[str]' = (), description: 'str' = '') ->
    ↪ 'FiniteBasis'
```

Definition. Construct a basis from a matrix whose columns are basis vectors.

Contract (D, C, H, R, X). Dimensions and names must be valid, basis columns must be exact and linearly independent, and atlas edges must agree with registered endpoints. Resolution composes only compatible paths and reports missing or conflicting routes explicitly.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_basis.py`, `examples/general_coordinate_atlas.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · bezout_defect_identity

Identity (q, a, t, k). Public research-manifest route `komorebi_math.bezout_defect_identity`. Reflected implementation `komorebi_math.coordinates.operators.bezout_defect_identity`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-OPERATORS`.

Manifest signature (s).

```
(values: 'Sequence[Scalar]', left: 'Sequence[Scalar]', right: 'Sequence[Scalar]') -> 'BezoutDefectIdentity'
```

Definition. Reconstruct the common finite interior from two coprime defects.

Contract (D, C, H, R, X). Polynomial coefficients and finite prefixes are normalized to exact scalars. Shift application, multiplication, and Bezout reconstruction validate lengths and finite support. Computed certificate routes, not unchecked record construction, establish the displayed identity.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_operators.py` covers the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 10, 18, and 64.

C.1C · `binomial_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.binomial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.binomial_transform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-COMBINATORIAL`.

Manifest signature (`s`).

```
(size: 'int', *, inverse: 'bool' = False, source: 'str' = 'sequence values', target: 'str' = 'binomial transform',
    ↪ budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512,
    ↪ maximum_horizon=4096, maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the finite binomial transform or its inverse.

Contract (`D, C, H, R, X`). Size must be nonnegative and remain within the supplied coordinate budget. The returned lower-triangular exact matrix follows the documented finite transform convention and exposes an exact inverse when requested.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17, 18, and 64.

C.1C · `classical_polynomial_catalog`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.classical_polynomial_catalog`. Reflected implementation `komorebi_math.coordinates.classical.classical_polynomial_catalog`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-CLASSICAL`.

Manifest signature (`s`).

```
() -> 'PolynomialFamilyCatalog'
```

Definition. Return the built-in exact graded polynomial-family catalog.

Contract (`D, C, H, R, X`). The function takes no arguments and returns the frozen `PolynomialFamilyCatalog` of built-in exact graded families and accepted aliases. The catalog is a lookup surface, not a proof of identities between families.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_classical.py` and `examples/classical_coordinate_families.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · companion_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.companion_matrix`. Reflected implementation `komorebi_math.coordinates.recurrence.companion_matrix`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-RECURRENCE`.

Manifest signature (s).

```
(coefficients: 'RecurrenceLike') -> 'Matrix'
```

Definition. Return the exact companion matrix for consecutive sequence states.

Contract (D, C, H, R, X). The recurrence coefficient vector must have positive order and the prefix must contain enough values for the requested analysis. Defect coordinates, companion evolution, inter-model transforms, and variation of constants use exact finite arithmetic.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_recurrence.py`, `examples/euler_to_fibonacci_coordinates.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · connection_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.connection_transform`. Reflected implementation `komorebi_math.coordinates.polynomials.connection_transform`. The same object is available through the curated stable routes `komorebi_math.stable.connection_transform`, `komorebi_math.v1.connection_transform`, and `komorebi_math.api.v1.connection_transform`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C1-COORD-POLYNOMIALS`.

Manifest signature (s).

```
(source: 'PolynomialFamily', target: 'PolynomialFamily', degree: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return target coordinates of source basis vectors through one degree.

Contract (D, C, H, R, X). Families must be graded with a nonzero leading term in every requested degree. Connection and operator matrices are exact, degree-bounded, and subject to the coordinate budget. Endpoint mismatches are rejected.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_polynomials.py` and `examples/euler_to_fibonacci_coordinates.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · coordinate_change_between_recurrences

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinate_change_between_recurrences`. Reflected implementation `komorebi_math.coordinates.recurrence.coordinate_change_between_recurrences`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-RECURRENCE`.

Manifest signature (s).

```
(source_coefficients: 'RecurrenceLike', target_coefficients: 'RecurrenceLike', length: 'int', *, source_name:
    ↪ 'str' = 'source recurrence', target_name: 'str' = 'target recurrence', budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the exact finite coordinate map between recurrence models.

Contract (D, C, H, R, X). The recurrence coefficient vector must have positive order and the prefix must contain enough values for the requested analysis. Defect coordinates, companion evolution, inter-model transforms, and variation of constants use exact finite arithmetic.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_recurrence.py`, `examples/euler_to_fibonacci_coordinates.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · discrete_fourier_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.discrete_fourier_transform`. Reflected implementation `komorebi_math.coordinates.numeric.discrete_fourier_transform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-NUMERIC`.

Manifest signature (s).

```
(size: 'int', *, unitary: 'bool' = True, inverse: 'bool' = False, tolerance: 'float' = 1e-12) ->
    ↪ 'NumericCoordinateTransform'
```

Definition. Return the finite discrete Fourier coordinate transform.

Contract (D, C, H, R, X). The input is a finite two-dimensional NumPy matrix with nonempty endpoint names and a positive finite tolerance. Inversion requires a square nonsingular matrix. Composition and certificates use tolerance-based numerical tests.

Guarantees (E, P, B, K). The implementation uses finite NumPy arithmetic and reports tolerance-based residual evidence. Dense inversion or condition estimation can require cubic time and quadratic storage. No GPU or network backend is selected implicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 16, 32, and 64.

C.1C · `euler_fibonacci_coordinates`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.euler_fibonacci_coordinates`. Reflected implementation `komorebi_math.coordinates.recurrence.euler_fibonacci_coordinates`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-RECURRENCE`.

Manifest signature (`s`).

```
(count: 'int') -> 'RecurrenceCoordinateRecord'
```

Definition. Return exact Fibonacci companion coordinates of a signed Euler prefix.

Contract (`D, C, H, R, X`). The recurrence coefficient vector must have positive order and the prefix must contain enough values for the requested analysis. Defect coordinates, companion evolution, inter-model transforms, and variation of constants use exact finite arithmetic.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_recurrence.py`, `examples/euler_to_fibonacci_coordinates.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · `euler_to_fibonacci_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.euler_to_fibonacci_transform`. Reflected implementation `komorebi_math.coordinates.polynomials.euler_to_fibonacci_transform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-POLYNOMIALS`.

Manifest signature (`s`).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return the Euler polynomial to Fibonacci polynomial connection.

Contract (`D, C, H, R, X`). Families must be graded with a nonzero leading term in every requested degree. Connection and operator matrices are exact, degree-bounded, and subject to the coordinate budget. Endpoint mismatches are rejected.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_polynomials.py` and `examples/euler_to_fibonacci_coordinates.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · forward_difference_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.forward_difference_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.forward_difference_transform`. The same object is available through the curated stable routes `komorebi_math.stable.forward_difference_transform`, `komorebi_math.v1.forward_difference_transform`, and `komorebi_math.api.v1.forward_difference_transform`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C1-COORD-COMBINATORIAL`.

Manifest signature (s).

```
(size: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Map sampled values `f(0),...,f(N)` to forward differences at zero.

Contract (D, C, H, R, X). Size must be nonnegative and remain within the supplied coordinate budget. The returned lower-triangular exact matrix follows the documented finite transform convention and exposes an exact inverse when requested.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17, 18, and 64.

C.1C · get_polynomial_family

Identity (q, a, t, k). Public research-manifest route `komorebi_math.get_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.get_polynomial_family`. The same object is available through the curated stable routes `komorebi_math.stable.get_polynomial_family`, `komorebi_math.v1.get_polynomial_family`, and `komorebi_math.api.v1.get_polynomial_family`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C1-COORD-CLASSICAL`.

Manifest signature (s).

```
(name: 'str') -> 'PolynomialFamily'
```

Definition. Return one built-in graded polynomial family by name or short alias.

Contract (D, C, H, R, X). Names are normalized against the built-in catalog. Unknown names are rejected, and returned families remain exact graded bases rather than numerical approximations.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_classical.py` and `examples/classical_coordinate_families.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · get_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.get_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.get_recurrence_model`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-FAMILIES`.

Manifest signature (s).

```
(name: 'str') -> 'RecurrenceModel'
```

Definition. Return one built-in recurrence model by normalized name.

Contract (D, C, H, R, X). A recurrence must have positive order and a nonempty name. Initial values are either absent or provide exactly one complete state. Analysis, synthesis, catalog lookup, and inter-model transport operate on finite exact prefixes.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_families_state.py` and `examples/recurrence_state_coordinate_atlas.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · intertwiner_space

Identity (q, a, t, k). Public research-manifest route `komorebi_math.intertwiner_space`. Reflected implementation `komorebi_math.coordinates.realization.intertwiner_space`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-REALIZATION`.

Manifest signature (s).

```
(source: 'Matrix', target: 'Matrix') -> 'IntertwinerSpace'
```

Definition. Return an exact basis of matrices satisfying `target*S=S*source`.

Contract (D, C, H, R, X). Matrices and vectors must have compatible exact dimensions. Observability and recovery are finite-horizon statements. Intertwiner solvers compute exact nullspaces, while record certificates verify displayed basis elements against the intertwining equation.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_realization.py`, `examples/recurrence_state_coordinate_atlas.py`, and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18, 31, and 64.

C.1C · load_coordinate_object

Identity (q, a, t, k). Public research-manifest route `komorebi_math.load_coordinate_object`. Reflected implementation `komorebi_math.coordinates.portable.load_coordinate_object`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path') -> 'Any'
```

Definition. Load and verify one registered portable coordinate object.

Contract (D, C, H, R, X). The path must contain a registered canonical coordinate envelope. The loader verifies JSON structure, type tag, schema version, and digest before reconstructing the object. Tampered, truncated, unknown, or unsupported records are rejected.

Guarantees (E, P, B, K). Encoding and digest verification are deterministic for the same registered value and schema version. Integrity is checked, but the digest is not an authentication signature. Runtime and memory are linear in encoded payload size apart from reconstruction of contained matrices.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_persistence.py` and `tests/test_coordinates_normalized_persistence.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 61 and 64.

C.1C · normalization_change_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.normalization_change_transform`. Reflected implementation `komorebi_math.coordinates.normalized.normalization_change_transform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-NORMALIZED`.

Manifest signature (s).

```
(source: 'WeightedMonomialBasis', target: 'WeightedMonomialBasis', degree: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the diagonal map preserving the underlying formal series.

Contract (D, C, H, R, X). Source and target weighted monomial bases must define compatible nonzero weights through the requested degree. The diagonal map preserves the represented formal series and remains subject to the coordinate budget.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_normalized_persistence.py` covers the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17, 21, and 64.

C.1C · observability_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.observability_matrix`. Reflected implementation `komorebi_math.coordinates.realization.observability_matrix`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-REALIZATION`.

Manifest signature (s).

```
(transition: 'Matrix', output: 'Sequence[Scalar]', horizon: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'Matrix'
```

Definition. Return rows `h^T A^n` for `0 <= n < horizon`.

Contract (D, C, H, R, X). Matrices and vectors must have compatible exact dimensions. Observability and recovery are finite-horizon statements. Intertwiner solvers compute exact nullspaces, while record certificates verify displayed basis elements against the intertwining equation.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_realization.py`, `examples/recurrence_state_coordinate_atlas.py`, and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18, 31, and 64.

C.1C · operator_change_of_coordinates

Identity (q, a, t, k). Public research-manifest route `komorebi_math.operator_change_of_coordinates`. Reflected implementation `komorebi_math.coordinates.polynomials.operator_change_of_coordinates`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-POLYNOMIALS`.

Manifest signature (s).

```
(operator_in_source: 'Matrix', source_to_target: 'CoordinateTransform') -> 'Matrix'
```

Definition. Conjugate an operator from source coordinates into target coordinates.

Contract (D, C, H, R, X). Families must be graded with a nonzero leading term in every requested degree. Connection and operator matrices are exact, degree-bounded, and subject to the coordinate budget. Endpoint mismatches are rejected.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_polynomials.py` and `examples/euler_to_fibonacci_coordinates.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 17 and 64.

C.1C · recover_initial_state

Identity (q, a, t, k). Public research-manifest route `komorebi_math.recover_initial_state`. Reflected implementation `komorebi_math.coordinates.realization.recover_initial_state`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-REALIZATION`.

Manifest signature (s).

```
(prefix: 'Sequence[Scalar]', transition: 'Matrix', output: 'Sequence[Scalar]', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'StateRecovery'
```

Definition. Recover or test a state against a finite output prefix.

Contract (D, C, H, R, X). Matrices and vectors must have compatible exact dimensions. Observability and recovery are finite-horizon statements. Intertwiner solvers compute exact nullspaces, while record certificates verify displayed basis elements against the intertwining equation.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_realization.py`, `examples/recurrence_state_coordinate_atlas.py`, and the independent verifier for coordinate facades cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18, 31, and 64.

C.1C · recurrence_model_catalog

Identity (q, a, t, k). Public research-manifest route `komorebi_math.recurrence_model_catalog`. Reflected implementation `komorebi_math.coordinates.families.recurrence_model_catalog`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-FAMILIES`.

Manifest signature (s).

```
() -> 'tuple[RecurrenceModel, ...]'
```

Definition. Return the built-in named recurrence models.

Contract (D, C, H, R, X). A recurrence must have positive order and a nonempty name. Initial values are either absent or provide exactly one complete state. Analysis, synthesis, catalog lookup, and inter-model transport operate on finite exact prefixes.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_families_state.py` and `examples/recurrence_state_coordinate_atlas.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1C · residue_class_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.residue_class_transform`. Reflected implementation `komorebi_math.coordinates.packet.residue_class_transform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-PACKET`.

Manifest signature (s).

```
(length: 'int', modulus: 'int') -> 'CoordinateTransform'
```

Definition. Return the exact polyphase permutation into residue-lane order.

Contract (D, C, H, R, X). Length must be nonnegative and modulus positive. The result is an exact permutation between natural order and residue-lane order, with dimensions and endpoints recorded explicitly.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 13, 18, and 64.

C.1C · save_coordinate_object

Identity (q, a, t, k). Public research-manifest route `komorebi_math.save_coordinate_object`. Reflected implementation `komorebi_math.coordinates.portable.save_coordinate_object`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path', value: 'Any', *, overwrite: 'bool' = False) -> 'Path'
```

Definition. Save any registered portable coordinate object.

Contract (D, C, H, R, X). The value must have a registered portable coordinate codec. Existing paths are refused unless overwrite is true. The function writes canonical JSON through a temporary file and atomic replacement, then returns the resolved path.

Guarantees (E, P, B, K). Encoding and digest verification are deterministic for the same registered value and schema version. Integrity is checked, but the digest is not an authentication signature. Runtime and memory are linear in encoded payload size apart from reconstruction of contained matrices.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_persistence.py` and `tests/test_coordinates_normalized_persistence.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 61 and 64.

C.1C · standard_basis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.standard_basis`. Reflected implementation `komorebi_math.coordinates.basis.standard_basis`. The same object is available through the curated stable routes `komorebi_math.stable.standard_basis`, `komorebi_math.v1.standard_basis`, and `komorebi_math.api.v1.standard_basis`. Those facade routes carry the frozen 1.x compatibility promise. The root route remains governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C1-COORD-BASIS`.

Manifest signature (s).

```
(dimension: 'int', *, name: 'str' = 'standard') -> 'FiniteBasis'
```

Definition. Return the standard basis of a rational vector space.

Contract (D, C, H, R, X). Dimensions and names must be valid, basis columns must be exact and linearly independent, and atlas edges must agree with registered endpoints. Resolution composes only compatible paths and reports missing or conflicting routes explicitly.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_basis.py`, `examples/general_coordinate_atlas.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 15, 16, and 64.

C.1C · `tensor_coordinate_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.tensor_coordinate_transform`. Reflected implementation `komorebi_math.coordinates.tensor.tensor_coordinate_transform`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-TENSOR`.

Manifest signature (s).

```
(transform: 'CoordinateTransform', variance: 'Sequence[Variance]') -> 'CoordinateTransform'
```

Definition. Return the induced transform on flattened tensor components.

Contract (D, C, H, R, X). Variance labels must be valid and the tensor rank is the length of that declaration. Contravariant axes use the coordinate matrix and covariant axes use its contragredient, with lexicographic flattening.

Guarantees (E, P, B, K). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_general_tensor_modular.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 16, 54, and 64.

C.1C · `variation_of_constants_prefix`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.variation_of_constants_prefix`. Reflected implementation `komorebi_math.coordinates.recurrence.variation_of_constants_prefix`. No curated stable or beta facade exports this research name in the reference manifest. The root route is governed by `[RESEARCH]` policy `pre-beta-additive` and is not part of the frozen stable compatibility promise. Manifest kind `function`. Profile `C1-COORD-RECURRENCE`.

Manifest signature (`s`).

```
(record: 'RecurrenceCoordinateRecord') -> 'Vector'
```

Definition. Reconstruct a prefix through the companion Green-kernel formula.

Contract (`D, C, H, R, X`). The recurrence coefficient vector must have positive order and the prefix must contain enough values for the requested analysis. Defect coordinates, companion evolution, inter-model transforms, and variation of constants use exact finite arithmetic.

Guarantees (`E, P, B, K`). Structural arithmetic is exact over integers and `Fraction` values. No tolerance, accelerator, network, or symbolic backend is consulted. Runtime and memory are finite and are dominated by matrix materialization, exact elimination, nullspace work, recurrence propagation, or polynomial convolution appropriate to the operation. Dense elimination can require cubic arithmetic-operation cost and exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. `tests/test_coordinates_recurrence.py`, `examples/euler_to_fibonacci_coordinates.py`, and `verification/block14_general_coordinate_audit.py` cover the applicable construction, roundtrip, certificate, failure, and persistence behavior. The source validator for coordinate facades also checks the exact signature, implementation identity, coordinate facade, anchor, and stable aliases. See Chapters 18 and 64.

C.1D Root core, structured algorithms, and exact integration: 82 entries

This root section documents three connected layers used throughout the manual. The core layer supplies typed operator grammars, finite realizations, packet decompositions, transfer graphs, morphisms, and seed-rank calculations. The algorithm layer turns those structures into packet intermediate representations, structured and low-rank execution, finite tree compilation, precision allocation, Krylov solves, discovery routines, and schedules. The integration layer provides exact measures, sparse polynomials, quadrature rules, finite error records, integral identities, and coordinate covectors.

Contract family	Cards
Core operator systems	25
Structured algorithms	19
Exact integration	38
Total	**82**

The boundary remains finite. Exact certificates apply only when the supplied scalar domain and hypotheses are exact. Numerical backends retain tolerances and residuals. Discovery routines remain heuristic, and callable integration or pushforward paths preserve their unchecked regularity assumptions. Dense materialization, rank tests, singular-value decompositions, path enumeration, and tensor or product growth remain explicit resource boundaries.

Core operator systems (25 cards).

C.1D · `AlgebraBasisResult`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.AlgebraBasisResult`. Reflected implementation `komorebi_math.core.algebra.AlgebraBasisResult`. The same runtime object is also available through `komorebi_math.core.AlgebraBasisResult`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-ALGEBRA`.

Manifest signature (s).

```
(basis: 'tuple[Any, ...]', dimension: 'int', certificate: 'Certificate') -> None
```

Definition. A finite basis, its dimension, and the certificate returned by operator-algebra closure.

Contract (D, C, H, R, X). Generator matrices must act on one finite coordinate space. The selected backend validates common square shape and closes the span under multiplication, optionally adjoining the identity. Exact backends use exact dependence tests. Floating backends use the declared tolerance and therefore return numerical certificates. `matrix_units` requires a positive size, and `AlgebraBasisResult` records the resulting basis, dimension, and certificate without recomputing closure.

Guarantees (E, P, B, K). The generated algebra has dimension at most the square of the matrix dimension, so closure terminates after finitely many independent additions. Matrix products and rank tests dominate cost. Exact scalar growth can dominate exact runs, while conditioning and tolerance selection control floating runs. A numerical containment decision is not promoted to an exact algebraic identity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algebra_quotients.py` and `tests/test_block18_frame_algebra.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · Arrow

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Arrow`. Reflected implementation `komorebi_math.core.grammar.Arrow`. The same runtime object is also available through `komorebi_math.core.Arrow`, `komorebi_math.stable.Arrow`, `komorebi_math.v1.Arrow`, `komorebi_math.api.v1.Arrow`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAMMAR`.

Manifest signature (s).

```
(name: 'str', source: 'str', target: 'str') -> None
```

Definition. A named typed generator from one grammar vertex to another.

Contract (D, C, H, R, X). Vertices and arrow names must be nonempty and unique, every arrow endpoint must be declared, and each operator word must be composable in application order. Linear relations may combine only parallel words. A realization supplies one positive dimension per vertex and a matrix of the required target-by-source shape for every arrow. Relation validation either produces a certificate or fails closed.

Guarantees (E, P, B, K). Grammar formation is finite and exact at the structural level. Path enumeration is bounded by the requested length and can grow exponentially with branching. Realization evaluation uses the selected linear algebra backend. Exact matrices yield exact relation checks, while floating matrices yield tolerance-dependent residual claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_grammar_realization.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9, 10, and 64.

C.1D · OperatorAlgebra

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OperatorAlgebra`. Reflected implementation `komorebi_math.core.algebra.OperatorAlgebra`. The same runtime object is also available through `komorebi_math.core.OperatorAlgebra`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-ALGEBRA`.

Manifest signature (s).

```
(generators: 'Mapping[str, Any] | Sequence[Any]', *, backend: 'str | LinearAlgebraBackend | None' = None,
   ↪ tolerance: 'float | None' = None, include_identity: 'bool' = True) -> 'None'
```

Definition. The unital finite dimensional matrix algebra generated by matrices.

Contract (D, C, H, R, X). Generator matrices must act on one finite coordinate space. The selected backend validates common square shape and closes the span under multiplication, optionally adjoining the identity. Exact backends use exact dependence tests. Floating backends use the declared tolerance and therefore return numerical certificates. `matrix_units` requires a positive size, and `AlgebraBasisResult` records the resulting basis, dimension, and certificate without recomputing closure. Principal public operations and properties are `basis`, `dimension`, `contains`, `certificate`, `seed_system`, `transfer_graph`.

Guarantees (E, P, B, K). The generated algebra has dimension at most the square of the matrix dimension, so closure terminates after finitely many independent additions. Matrix products and rank tests dominate cost. Exact scalar growth can dominate exact runs, while conditioning and tolerance selection control floating runs. A numerical containment decision is not promoted to an exact algebraic identity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algebra_quotients.py` and `tests/test_block18_frame_algebra.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · OperatorGrammar

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OperatorGrammar`. Reflected implementation `komorebi_math.core.grammar.OperatorGrammar`. The same runtime object is also available through `komorebi_math.core.OperatorGrammar`, `komorebi_math.stable.OperatorGrammar`, `komorebi_math.v1.OperatorGrammar`, `komorebi_math.api.v1.OperatorGrammar`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAMMAR`.

Manifest signature (s).

```
(vertices: 'Iterable[str]', arrows: 'Mapping[str, tuple[str, str]] | Iterable[Arrow]', relations:
   ↪ 'Iterable[OperatorRelation]' = ()) -> 'None'
```

Definition. A finite quiver with optional linear path relations.

Contract (D, C, H, R, X). Vertices and arrow names must be nonempty and unique, every arrow endpoint must be declared, and each operator word must be composable in application order. Linear relations may combine only parallel words. A realization supplies one positive dimension per vertex and a matrix of the required target-by-source shape for every arrow. Relation validation either produces a certificate or fails closed. Principal public operations and properties are `vertices`, `arrows`, `relations`, `arrow`, `identity`, `word`, `relation`, `add_relation`, `paths`.

Guarantees (E, P, B, K). Grammar formation is finite and exact at the structural level. Path enumeration is bounded by the requested length and can grow exponentially with branching. Realization evaluation uses the selected linear algebra backend. Exact matrices yield exact relation checks, while floating matrices yield tolerance-dependent residual claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_grammar_realization.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource

paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9, 10, and 64.

C.1D · OperatorMorphism

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OperatorMorphism`. Reflected implementation `komorebi_math.core.morphisms.OperatorMorphism`. The same runtime object is also available through `komorebi_math.core.OperatorMorphism`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-MORPHISM`.

Manifest signature (s).

```
(source_operators: 'Mapping[str, Any]', target_operators: 'Mapping[str, Any]', linear_map: 'Any', operator_map:
    ↪ 'Mapping[str, str]', backend: 'Any', tolerance: 'float') -> None
```

Definition. A finite linear intertwiner between two named operator families.

Contract (D, C, H, R, X). A morphism must match source and target dimensions, map every named operator to an existing target operator, and satisfy the appropriate intertwining equations. Packet morphisms also validate the declared packet image, while seed morphisms validate supplied seed images or derive them through the linear map. Certificates expose all residuals and unchecked assumptions. Principal public operations and properties are `create`, `certificate`.

Guarantees (E, P, B, K). Shape and name checks are exact. Intertwining is exact for exact backends and numerical for floating backends. Verification cost is dominated by finite matrix products and residual norms. A valid finite morphism certificate establishes the listed equations only, not an equivalence of arbitrary external models.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_morphisms.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9 through 11 and Chapter 64.

C.1D · OperatorRealization

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OperatorRealization`. Reflected implementation `komorebi_math.core.realization.OperatorRealization`. The same runtime object is also available through `komorebi_math.core.OperatorRealization`, `komorebi_math.stable.OperatorRealization`, `komorebi_math.v1.OperatorRealization`, `komorebi_math.api.v1.OperatorRealization`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAMMAR`.

Manifest signature (s).

```
(grammar: 'OperatorGrammar', spaces: 'Mapping[str, int]', operators: 'Mapping[str, Any]', *, backend: 'str |
    ↪ LinearAlgebraBackend | None' = None, validate_relations: 'bool' = True, tolerance: 'float | None' = None) ->
    ↪ 'None'
```

Definition. An assignment of vector space dimensions and matrices to a typed grammar.

Contract (D, C, H, R, X). Vertices and arrow names must be nonempty and unique, every arrow endpoint must be declared, and each operator word must be composable in application order. Linear relations may combine only parallel words. A realization supplies one positive dimension per vertex and a matrix of the required target-by-source shape for every arrow. Relation validation either produces a certificate or fails closed. Principal public operations and properties are `evaluate`, `relation_matrix`, `relation_residuals`, `relation_certificate`, `path_operators`, `loop_operators`.

Guarantees (E, P, B, K). Grammar formation is finite and exact at the structural level. Path enumeration is bounded by the requested length and can grow exponentially with branching. Realization evaluation uses the selected lin-

ear algebra backend. Exact matrices yield exact relation checks, while floating matrices yield tolerance-dependent residual claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_grammar_realization.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9, 10, and 64.

C.1D · `OperatorRelation`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OperatorRelation`. Reflected implementation `komorebi_math.core.grammar.OperatorRelation`. The same runtime object is also available through `komorebi_math.core.OperatorRelation`, `komorebi_math.stable.OperatorRelation`, `komorebi_math.v1.OperatorRelation`, `komorebi_math.api.v1.OperatorRelation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAMMAR`.

Manifest signature (s).

```
(name: 'str', terms: 'tuple[tuple[Any, OperatorWord], ...]') -> None
```

Definition. A linear relation among parallel operator words.

Contract (D, C, H, R, X). Vertices and arrow names must be nonempty and unique, every arrow endpoint must be declared, and each operator word must be composable in application order. Linear relations may combine only parallel words. A realization supplies one positive dimension per vertex and a matrix of the required target-by-source shape for every arrow. Relation validation either produces a certificate or fails closed. Principal public operations and properties are `source`, `target`.

Guarantees (E, P, B, K). Grammar formation is finite and exact at the structural level. Path enumeration is bounded by the requested length and can grow exponentially with branching. Realization evaluation uses the selected linear algebra backend. Exact matrices yield exact relation checks, while floating matrices yield tolerance-dependent residual claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_grammar_realization.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9, 10, and 64.

C.1D · `OperatorWord`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OperatorWord`. Reflected implementation `komorebi_math.core.grammar.OperatorWord`. The same runtime object is also available through `komorebi_math.core.OperatorWord`, `komorebi_math.stable.OperatorWord`, `komorebi_math.v1.OperatorWord`, `komorebi_math.api.v1.OperatorWord`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAMMAR`.

Manifest signature (s).

```
(arrows: 'tuple[str, ...]', source: 'str', target: 'str') -> None
```

Definition. A typed path written in the order in which arrows act.

Contract (D, C, H, R, X). Vertices and arrow names must be nonempty and unique, every arrow endpoint must be declared, and each operator word must be composable in application order. Linear relations may combine only parallel words. A realization supplies one positive dimension per vertex and a matrix of the required target-by-source shape for every arrow. Relation validation either produces a certificate or fails closed. Principal public operations and properties are `length`, `is_identity`.

Guarantees (E, P, B, K). Grammar formation is finite and exact at the structural level. Path enumeration is bounded by the requested length and can grow exponentially with branching. Realization evaluation uses the selected linear algebra backend. Exact matrices yield exact relation checks, while floating matrices yield tolerance-dependent residual claims.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_grammar_realization.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9, 10, and 64.

C.1D · PacketCoordinates

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketCoordinates`. Reflected implementation `komorebi_math.core.packets.PacketCoordinates`. The same runtime object is also available through `komorebi_math.core.PacketCoordinates`, `komorebi_math.stable.PacketCoordinates`, `komorebi_math.v1.PacketCoordinates`, `komorebi_math.api.v1.PacketCoordinates`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-PACKET`.

Manifest signature (s).

```
(system: "'PacketSystem'", values: 'tuple[Any, ...]') -> None
```

Definition. One tuple of packet-local coordinate vectors tied to a validated packet system.

Contract (D, C, H, R, X). A packet system is a finite family of square projectors on one ambient space. Validation checks idempotence, pairwise annihilation, and completeness. Coordinates contain one vector per packet with the corresponding packet dimension. Packet operators store every target-by-source block with exact shape, and composition, powers, adjoints, tensor products, analysis, and synthesis preserve declared packet order. Principal public operations and properties are `reconstruct`, `support`, `as_dict`.

Guarantees (E, P, B, K). Structural packet identities are exact on exact backends and tolerance-dependent on numerical backends. Explicit block storage is quadratic in packet count and proportional to the total stored entries. Materialization can require the full ambient matrix. Certificates cover the finite supplied projectors and blocks, not an infinite decomposition.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_packets.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11, 19, and 64.

C.1D · PacketMorphism

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketMorphism`. Reflected implementation `komorebi_math.core.morphisms.PacketMorphism`. The same runtime object is also available through `komorebi_math.core.PacketMorphism`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-MORPHISM`.

Manifest signature (s).

```
(source: 'PacketSystem', target: 'PacketSystem', linear_map: 'Any', packet_map: 'Mapping[str, tuple[str, ...]]')
   ↪  -> None
```

Definition. A linear map between packet systems together with the declared target packets receiving each source packet.

Contract (D, C, H, R, X). A morphism must match source and target dimensions, map every named operator to an existing target operator, and satisfy the appropriate intertwining equations. Packet morphisms also validate the

declared packet image, while seed morphisms validate supplied seed images or derive them through the linear map. Certificates expose all residuals and unchecked assumptions. Principal public operations and properties are `certificate`.

Guarantees (`E, P, B, K`). Shape and name checks are exact. Intertwining is exact for exact backends and numerical for floating backends. Verification cost is dominated by finite matrix products and residual norms. A valid finite morphism certificate establishes the listed equations only, not an equivalence of arbitrary external models.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_morphisms.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9 through 11 and Chapter 64.

C.1D · `PacketOperator`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.PacketOperator`. Reflected implementation `komorebi_math.core.operators.PacketOperator`. The same runtime object is also available through `komorebi_math.core.PacketOperator`, `komorebi_math.stable.PacketOperator`, `komorebi_math.v1.PacketOperator`, `komorebi_math.api.v1.PacketOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-PACKET`.

Manifest signature (`s`).

```
(source: 'PacketSystem', target: 'PacketSystem', blocks: 'tuple[tuple[Any, ...], ...]') -> None
```

Definition. An operator represented by all target by source packet blocks.

Contract (`D, C, H, R, X`). A packet system is a finite family of square projectors on one ambient space. Validation checks idempotence, pairwise annihilation, and completeness. Coordinates contain one vector per packet with the corresponding packet dimension. Packet operators store every target-by-source block with exact shape, and composition, powers, adjoints, tensor products, analysis, and synthesis preserve declared packet order. Principal public operations and properties are `backend`, `from_operator`, `reconstruct`, `certificate`, `apply`, `apply_coordinates`, `compose`, `adjoint`, `tensor`, `is_endomorphism`, `power`, `block_norms`, `is_block_diagonal`, `support_mask`.

Guarantees (`E, P, B, K`). Structural packet identities are exact on exact backends and tolerance-dependent on numerical backends. Explicit block storage is quadratic in packet count and proportional to the total stored entries. Materialization can require the full ambient matrix. Certificates cover the finite supplied projectors and blocks, not an infinite decomposition.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_packets.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11, 19, and 64.

C.1D · `PacketSystem`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.PacketSystem`. Reflected implementation `komorebi_math.core.packets.PacketSystem`. The same runtime object is also available through `komorebi_math.core.PacketSystem`, `komorebi_math.stable.PacketSystem`, `komorebi_math.beta.PacketSystem`, `komorebi_math.v1.PacketSystem`, `komorebi_math.api.v1.PacketSystem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-PACKET`.

Manifest signature (s).

```
(projectors: 'Sequence[Any]', *, names: 'Sequence[str] | None' = None, backend: 'str | LinearAlgebraBackend | None'
   ↪  = None, tolerance: 'float | None' = None, validate: 'bool | None' = None) -> 'None'
```

Definition. A complete finite family of pairwise annihilating idempotents.

Contract (D, C, H, R, X). A packet system is a finite family of square projectors on one ambient space. Validation checks idempotence, pairwise annihilation, and completeness. Coordinates contain one vector per packet with the corresponding packet dimension. Packet operators store every target-by-source block with exact shape, and composition, powers, adjoints, tensor products, analysis, and synthesis preserve declared packet order. Principal public operations and properties are `index`, `certificate`, `hilbert_certificate`, `analyze`, `synthesize`, `support`, `packet_dimensions`, `aggregate`, `tensor`, `dual`, `equivalent`, `transport`, `restrict`, `quotient`, `block_diagonal_projection`.

Guarantees (E, P, B, K). Structural packet identities are exact on exact backends and tolerance-dependent on numerical backends. Explicit block storage is quadratic in packet count and proportional to the total stored entries. Materialization can require the full ambient matrix. Certificates cover the finite supplied projectors and blocks, not an infinite decomposition.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_packets.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11, 19, and 64.

C.1D · SeedMorphism

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SeedMorphism`. Reflected implementation `komorebi_math.core.morphisms.SeedMorphism`. The same runtime object is also available through `komorebi_math.core.SeedMorphism`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-MORPHISM`.

Manifest signature (s).

```
(source: 'SeedSystem', target: 'SeedSystem', linear_map: 'Any', operator_map: 'Mapping[str, str]', seed_images:
   ↪  'Sequence[Any] | None' = None) -> None
```

Definition. An operator intertwiner that also transports a finite seed family.

Contract (D, C, H, R, X). A morphism must match source and target dimensions, map every named operator to an existing target operator, and satisfy the appropriate intertwining equations. Packet morphisms also validate the declared packet image, while seed morphisms validate supplied seed images or derive them through the linear map. Certificates expose all residuals and unchecked assumptions. Principal public operations and properties are `certificate`.

Guarantees (E, P, B, K). Shape and name checks are exact. Intertwining is exact for exact backends and numerical for floating backends. Verification cost is dominated by finite matrix products and residual norms. A valid finite morphism certificate establishes the listed equations only, not an equivalence of arbitrary external models.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_morphisms.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 9 through 11 and Chapter 64.

C.1D · SeedSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SeedSystem`. Reflected implementation `komorebi_math.core.seeds.SeedSystem`. The same runtime object is also available through `komorebi_math.core.SeedSystem`, `komorebi_math.stable.SeedSystem`, `komorebi_math.v1.SeedSystem`, `komorebi_math.api.v1.SeedSystem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(operators: 'Mapping[str, Any] | Sequence[Any]', seeds: 'Sequence[Any]', *, backend: 'str | LinearAlgebraBackend |
    ↪ None' = None, tolerance: 'float | None' = None) -> 'None'
```

Definition. A finite family of operators acting on a finite seed family.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require non-negative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space. Principal public operations and properties are `exact`, `hull_vectors`, `hull_basis`, `hull_dimension`, `is_generating`, `generation_certificate`, `orbit_layers`, `presentation`, `minimum_standard_basis_seeds`.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · SupportPreorder

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SupportPreorder`. Reflected implementation `komorebi_math.core.graphs.SupportPreorder`. The same runtime object is also available through `komorebi_math.core.SupportPreorder`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAPH`.

Manifest signature (s).

```
(relation: 'Sequence[Sequence[bool | int]]') -> 'None'
```

Definition. A reflexive transitive support relation on packet labels.

Contract (D, C, H, R, X). Graph relations are finite square Boolean matrices. Transfer graphs use source-by-target adjacency. Support preorders require reflexivity and transitivity. Path routines honor exact source, target, and length bounds, and packet path reconstruction combines only structurally admissible blocks. Invalid vertices, negative lengths, or incompatible packet operators are rejected. Principal public operations and properties are `order`, `is_reflexive`, `is_transitive`, `equivalence_classes`, `strict_class_graph`, `strict_ideal_nilpotency_bound`.

Guarantees (E, P, B, K). Reachability, strongly connected components, condensation, and topological operations are combinatorial and deterministic. Enumerating all fixed-length paths can grow exponentially. Reconstructed blocks inherit the exactness or tolerance status of the packet operator and backend. Graph certificates describe finite support structure, not analytic convergence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_graphs.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms,

and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11 and 64.

C.1D · TransferGraph

Identity (q, a, t, k). Public research-manifest route `komorebi_math.TransferGraph`. Reflected implementation `komorebi_math.core.graphs.TransferGraph`. The same runtime object is also available through `komorebi_math.core.TransferGraph`, `komorebi_math.stable.TransferGraph`, `komorebi_math.v1.TransferGraph`, `komorebi_math.api.v1.TransferGraph`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-CORE-GRAPH`.

Manifest signature (s).

```
(adjacency: 'Sequence[Sequence[bool | int]]', *, names: 'Sequence[str] | None' = None) -> 'None'
```

Definition. A finite directed graph with adjacency stored as source by target.

Contract (D, C, H, R, X). Graph relations are finite square Boolean matrices. Transfer graphs use source-by-target adjacency. Support preorders require reflexivity and transitivity. Path routines honor exact source, target, and length bounds, and packet path reconstruction combines only structurally admissible blocks. Invalid vertices, negative lengths, or incompatible packet operators are rejected. Principal public operations and properties are `from_packet_operator`, `from_operator_family`, `successors`, `predecessors`, `reachable`, `paths`, `strongly_connected_components`, `condensation`, `source_components`, `is_acyclic`, `topological_order`, `longest_path_vertices`, `source_component_certificate`, `edges`.

Guarantees (E, P, B, K). Reachability, strongly connected components, condensation, and topological operations are combinatorial and deterministic. Enumerating all fixed-length paths can grow exponentially. Reconstructed blocks inherit the exactness or tolerance status of the packet operator and backend. Graph certificates describe finite support structure, not analytic convergence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_graphs.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11 and 64.

C.1D · block_from_paths

Identity (q, a, t, k). Public research-manifest route `komorebi_math.block_from_paths`. Reflected implementation `komorebi_math.core.transfer.block_from_paths`. The same runtime object is also available through `komorebi_math.core.block_from_paths`, `komorebi_math.stable.block_from_paths`, `komorebi_math.v1.block_from_paths`, `komorebi_math.api.v1.block_from_paths`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-GRAPH`.

Manifest signature (s).

```
(operator: 'PacketOperator', *, source: 'int', target: 'int', length: 'int', tolerance: 'float | None' = None) ->
    ↪ 'ComputationResult[Any]'
```

Definition. Reconstruct one block of an operator power from packet paths.

Contract (D, C, H, R, X). Graph relations are finite square Boolean matrices. Transfer graphs use source-by-target adjacency. Support preorders require reflexivity and transitivity. Path routines honor exact source, target, and length bounds, and packet path reconstruction combines only structurally admissible blocks. Invalid vertices, negative lengths, or incompatible packet operators are rejected.

Guarantees (E, P, B, K). Reachability, strongly connected components, condensation, and topological operations are combinatorial and deterministic. Enumerating all fixed-length paths can grow exponentially. Reconstructed blocks inherit the exactness or tolerance status of the packet operator and backend. Graph certificates describe finite support structure, not analytic convergence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_graphs.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11 and 64.

C.1D · cyclic_span

Identity (q, a, t, k). Public research-manifest route `komorebi_math.cyclic_span`. Reflected implementation `komorebi_math.core.seeds.cyclic_span`. The same runtime object is also available through `komorebi_math.core.cyclic_span`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(operators: 'Mapping[str, Any] | Sequence[Any]', seeds: 'Sequence[Any]', *, backend: 'str | LinearAlgebraBackend |
    ↪ None' = None, tolerance: 'float | None' = None) -> 'ComputationResult[Any]'
```

Definition. Compute the finite operator hull generated by the supplied seeds.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require nonnegative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · independent_direct_sum_seed_rank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.independent_direct_sum_seed_rank`. Reflected implementation `komorebi_math.core.seeds.independent_direct_sum_seed_rank`. The same runtime object is also available through `komorebi_math.core.independent_direct_sum_seed_rank`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(seed_ranks: 'Sequence[int]') -> 'int'
```

Definition. Return the exact generator number for independent product actions.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require nonnegative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · `matrix_units`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.matrix_units`. Reflected implementation `komorebi_math.core.algebra.matrix_units`. The same runtime object is also available through `komorebi_math.core.matrix_units`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-ALGEBRA`.

Manifest signature (s).

```
(size: 'int', *, backend: 'str | LinearAlgebraBackend | None' = None) -> 'tuple[Any, ...]'
```

Definition. Return the standard matrix units of the requested square size.

Contract (D, C, H, R, X). Generator matrices must act on one finite coordinate space. The selected backend validates common square shape and closes the span under multiplication, optionally adjoining the identity. Exact backends use exact dependence tests. Floating backends use the declared tolerance and therefore return numerical certificates. `matrix_units` requires a positive size, and `AlgebraBasisResult` records the resulting basis, dimension, and certificate without recomputing closure.

Guarantees (E, P, B, K). The generated algebra has dimension at most the square of the matrix dimension, so closure terminates after finitely many independent additions. Matrix products and rank tests dominate cost. Exact scalar growth can dominate exact runs, while conditioning and tolerance selection control floating runs. A numerical containment decision is not promoted to an exact algebraic identity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algebra_quotients.py` and `tests/test_block18_frame_algebra.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · `path_contributions`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.path_contributions`. Reflected implementation `komorebi_math.core.transfer.path_contributions`. The same runtime object is also available through `komorebi_math.core.path_contributions`, `komorebi_math.stable.path_contributions`, `komorebi_math.v1.path_contributions`, `komorebi_math.api.v1.path_contributions`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-GRAPH`.

Manifest signature (s).

```
(operator: 'PacketOperator', *, source: 'int', target: 'int', length: 'int', tolerance: 'float | None' = None) ->
    ↪ 'tuple[TransferPath, ...]'
```

Definition. Return every nonzero structural path contribution of fixed length.

Contract (D, C, H, R, X). Graph relations are finite square Boolean matrices. Transfer graphs use source-by-target adjacency. Support preorders require reflexivity and transitivity. Path routines honor exact source, target, and length bounds, and packet path reconstruction combines only structurally admissible blocks. Invalid vertices, negative lengths, or incompatible packet operators are rejected.

Guarantees (E, P, B, K). Reachability, strongly connected components, condensation, and topological operations are combinatorial and deterministic. Enumerating all fixed-length paths can grow exponentially. Reconstructed blocks

inherit the exactness or tolerance status of the packet operator and backend. Graph certificates describe finite support structure, not analytic convergence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_graphs.py` and `tests/test_operators_transfer.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 11 and 64.

C.1D · semisimple_seed_rank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.semisimple_seed_rank`. Reflected implementation `komorebi_math.core.seeds.semisimple_seed_rank`. The same runtime object is also available through `komorebi_math.core.semisimple_seed_rank`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(block_dimensions: 'Sequence[int]', multiplicities: 'Sequence[int]') -> 'int'
```

Definition. Return the generator number from semisimple block multiplicities.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require nonnegative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · shared_direct_sum_seed_bounds

Identity (q, a, t, k). Public research-manifest route `komorebi_math.shared_direct_sum_seed_bounds`. Reflected implementation `komorebi_math.core.seeds.shared_direct_sum_seed_bounds`. The same runtime object is also available through `komorebi_math.core.shared_direct_sum_seed_bounds`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(seed_ranks: 'Sequence[int]') -> 'tuple[int, int]'
```

Definition. Return the general lower and upper bounds for a shared acting algebra.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require nonnegative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank

tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · `single_operator_seed_rank`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.single_operator_seed_rank`. Reflected implementation `komorebi_math.core.seeds.single_operator_seed_rank`. The same runtime object is also available through `komorebi_math.core.single_operator_seed_rank`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(operator: 'Any') -> 'int'
```

Definition. Return the exact generator number for a rational matrix as a Q[t] module.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require nonnegative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

C.1D · `tensor_seed_rank_upper_bound`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.tensor_seed_rank_upper_bound`. Reflected implementation `komorebi_math.core.seeds.tensor_seed_rank_upper_bound`. The same runtime object is also available through `komorebi_math.core.tensor_seed_rank_upper_bound`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-CORE-SEED`.

Manifest signature (s).

```
(left_rank: 'int', right_rank: 'int') -> 'int'
```

Definition. Return the product upper bound for tensor product seed rank.

Contract (D, C, H, R, X). Operators must be square and share one ambient dimension. Seeds must have that dimension. The cyclic hull repeatedly applies every operator until rank stabilizes. Closed-form seed-rank helpers require nonnegative integer ranks or valid square matrices and implement the stated direct-sum, semisimple, single-operator, or tensor bound rather than searching an unbounded space.

Guarantees (E, P, B, K). Finite hull construction adds at most as many independent directions as the ambient dimension. Exact backends produce exact ranks and span certificates. Floating backends depend on numerical rank tolerance. Single-operator rank uses rational primary decomposition and may incur polynomial factorization and exact nullity costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_seeds.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 10 and 64.

Structured algorithms (19 cards).

C.1D · `BlockDiagonalLowRankOperator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.BlockDiagonalLowRankOperator`. Reflected implementation `komorebi_math.algorithms.low_rank.BlockDiagonalLowRankOperator`. The same runtime object is also available through `komorebi_math.algorithms.BlockDiagonalLowRankOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-LOW-RANK`.

Manifest signature (s).

```
(diagonal: 'BlockDiagonalOperator', correction: 'LowRankOperator') -> None
```

Definition. A square block diagonal operator plus one low rank correction.

Contract (D, C, H, R, X). Low-rank factors must be two-dimensional, share a common rank, and represent `left @ right.conj().T`. A block-diagonal low-rank operator requires a square diagonal part and a correction of matching shape. Recompression validates the requested rank and tolerance, forms a small core, and truncates through singular-value decomposition. Principal public operations and properties are `from_factors`, `shape`, `dtype`, `rank_bound`, `apply`, `materialize`, `adjoint`, `storage_entries`, `flop_count`, `solve`, `exact_product`, `recompress`.

Guarantees (E, P, B, K). Application and storage scale with factor rank rather than the full dense matrix when the rank is small. Recompression and Woodbury-style solves are numerical and depend on singular-value and conditioning thresholds. Materialization remains available but loses the storage advantage. Rank bounds are finite upper bounds, not minimum-rank proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_low_rank.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · `BlockDiagonalOperator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.BlockDiagonalOperator`. Reflected implementation `komorebi_math.algorithms.structured.BlockDiagonalOperator`. The same runtime object is also available through `komorebi_math.algorithms.BlockDiagonalOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-STRUCTURED`.

Manifest signature (s).

```
(blocks: 'tuple[StructuredOperator | Array, ...]', names: 'tuple[str, ...] | None' = None) -> None
```

Definition. Square direct sum of independently executable structured blocks.

Contract (D, C, H, R, X). Structured operators expose a common finite `shape`, `dtype`, `apply`, `adjoint`, `materialize`, storage, flop, residual, and solve contract. Dense matrices must be rectangular. Block-diagonal operands must be square and dimension-compatible. Circulant operators are determined by one finite first column. Walsh-Hadamard dimensions must be positive powers of two. Principal public operations and properties are `shape`, `dtype`, `apply`, `solve`, `materialize`, `adjoint`, `storage_entries`, `flop_count`, `block`.

Guarantees (E, P, B, K). Applications use the represented structure rather than silently materializing a dense matrix: blockwise execution for direct sums, FFT execution for circulants, and butterfly execution for Walsh-Hadamard

transforms. Explicit `materialize` and generic `solve` may allocate dense matrices. Residual certificates are numerical unless the underlying array arithmetic is exact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_structured.py` and `tests/test_algorithms_complexity_benchmarks.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · `CirculantOperator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CirculantOperator`. Reflected implementation `komorebi_math.algorithms.structured.CirculantOperator`. The same runtime object is also available through `komorebi_math.algorithms.CirculantOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-STRUCTURED`.

Manifest signature (s).

```
(first_column: 'Array') -> None
```

Definition. Circulant matrix applied through a discrete Fourier transform.

Contract (D, C, H, R, X). Structured operators expose a common finite `shape`, `dtype`, `apply`, `adjoint`, `materialize`, storage, flop, residual, and solve contract. Dense matrices must be rectangular. Block-diagonal operands must be square and dimension-compatible. Circulant operators are determined by one finite first column. Walsh-Hadamard dimensions must be positive powers of two. Principal public operations and properties are `shape`, `dtype`, `apply`, `materialize`, `adjoint`, `storage_entries`, `flop_count`.

Guarantees (E, P, B, K). Applications use the represented structure rather than silently materializing a dense matrix: blockwise execution for direct sums, FFT execution for circulants, and butterfly execution for Walsh-Hadamard transforms. Explicit `materialize` and generic `solve` may allocate dense matrices. Residual certificates are numerical unless the underlying array arithmetic is exact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_structured.py` and `tests/test_algorithms_complexity_benchmarks.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · `DenseOperator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.DenseOperator`. Reflected implementation `komorebi_math.algorithms.structured.DenseOperator`. The same runtime object is also available through `komorebi_math.algorithms.DenseOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-STRUCTURED`.

Manifest signature (s).

```
(matrix: 'Array') -> None
```

Definition. Explicit dense matrix implementation of the structured contract.

Contract (D, C, H, R, X). Structured operators expose a common finite `shape`, `dtype`, `apply`, `adjoint`, `materialize`, storage, flop, residual, and solve contract. Dense matrices must be rectangular. Block-diagonal operands must be square and dimension-compatible. Circulant operators are determined by one finite first column. Walsh-Hadamard dimensions must be positive powers of two. Principal public operations and properties are `shape`, `dtype`, `apply`, `materialize`, `adjoint`, `storage_entries`, `flop_count`.

Guarantees (E, P, B, K). Applications use the represented structure rather than silently materializing a dense matrix: blockwise execution for direct sums, FFT execution for circulants, and butterfly execution for Walsh-Hadamard

transforms. Explicit `materialize` and generic `solve` may allocate dense matrices. Residual certificates are numerical unless the underlying array arithmetic is exact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_structured.py` and `tests/test_algorithms_complexity_benchmarks.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · DTypeChoice

Identity (q, a, t, k). Public research-manifest route `komorebi_math.DTypeChoice`. Reflected implementation `komorebi_math.algorithms.precision.DTypeChoice`. The same runtime object is also available through `komorebi_math.algorithms.DTypeChoice`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-PRECISION`.

Manifest signature (s).

```
(name: 'str', cost: 'float', error_units: 'int', dtype: 'str | None' = None) -> None
```

Definition. One discrete precision option with a finite cost, integer error weight, and optional backend dtype label.

Contract (D, C, H, R, X). Each precision choice has a finite cost and a nonnegative integer error weight. Every operation must provide at least one option. The assignment routine solves the finite multiple-choice budget problem and returns `None` when no combination satisfies the integer error budget.

Guarantees (E, P, B, K). Dynamic programming is deterministic and exact for the discretized cost and error model. Runtime and memory scale with the number of choices times the integer budget. The result optimizes the supplied model only. It does not infer rounding error or hardware cost that was not encoded in the options.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_precision.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · LowRankOperator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LowRankOperator`. Reflected implementation `komorebi_math.algorithms.low_rank.LowRankOperator`. The same runtime object is also available through `komorebi_math.algorithms.LowRankOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-LOW-RANK`.

Manifest signature (s).

```
(left: 'Array', right: 'Array') -> None
```

Definition. A finite operator represented as `left @ right.conj().T`.

Contract (D, C, H, R, X). Low-rank factors must be two-dimensional, share a common rank, and represent `left @ right.conj().T`. A block-diagonal low-rank operator requires a square diagonal part and a correction of matching shape. Recompression validates the requested rank and tolerance, forms a small core, and truncates through singular-value decomposition. Principal public operations and properties are `rank_bound`, `shape`, `dtype`, `apply`, `materialize`, `adjoint`, `storage_entries`, `flop_count`.

Guarantees (E, P, B, K). Application and storage scale with factor rank rather than the full dense matrix when the rank is small. Recompression and Woodbury-style solves are numerical and depend on singular-value and conditioning thresholds. Materialization remains available but loses the storage advantage. Rank bounds are finite upper bounds, not minimum-rank proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_low_rank.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · PacketIR

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketIR`. Reflected implementation `komorebi_math.algorithms.ir.PacketIR`. The same runtime object is also available through `komorebi_math.algorithms.PacketIR`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-PACKET-IR`.

Manifest signature (s).

```
(source_layout: 'PacketLayout', target_layout: 'PacketLayout', blocks: 'Mapping[Address, StructuredOperator |
    ↪ Any]', metadata: 'Mapping[str, Any]' = <factory>) -> None
```

Definition. A finite operator as a map from source packets to target packets.

Contract (D, C, H, R, X). Packet layouts require positive packet sizes and unique optional names. Packet-IR block addresses use `(target, source)` order, and every stored block must match the corresponding target-by-source dimensions. Missing blocks are structural zeros. Composition, adjoint, tensor product, powers, and dense conversion preserve the declared layouts. Principal public operations and properties are `square`, `from_dense`, `shape`, `dtype`, `support`, `stored_entries`, `flop_count`, `block`, `materialize`, `apply`, `adjoint`, `compose`, `power`, `tensor`, `diagonal_part`, `certificate`.

Guarantees (E, P, B, K). Sparse packet execution touches stored blocks only, with work proportional to their dimensions and count. Dense materialization scales with the full source and target dimensions. Support and storage counts are exact structural facts. Numerical block values retain their backend precision and do not acquire an exactness claim.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_layout_ir.py` and `tests/test_algorithms_support.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 28.

C.1D · PacketLayout

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketLayout`. Reflected implementation `komorebi_math.algorithms.layout.PacketLayout`. The same runtime object is also available through `komorebi_math.algorithms.PacketLayout`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-PACKET-IR`.

Manifest signature (s).

```
(sizes: 'tuple[int, ...]', names: 'tuple[str, ...] | None' = None) -> None
```

Definition. A contiguous finite packet decomposition of one coordinate space.

Contract (D, C, H, R, X). Packet layouts require positive packet sizes and unique optional names. Packet-IR block addresses use `(target, source)` order, and every stored block must match the corresponding target-by-source dimensions. Missing blocks are structural zeros. Composition, adjoint, tensor product, powers, and dense conversion preserve the declared layouts. Principal public operations and properties are `equal`, `from_packet_system`, `index`, `packet_slice`, `packet_size`, `split`, `merge`, `crossed`, `permutation`, `stored_coordinate_count`.

Guarantees (E, P, B, K). Sparse packet execution touches stored blocks only, with work proportional to their dimensions and count. Dense materialization scales with the full source and target dimensions. Support and storage

counts are exact structural facts. Numerical block values retain their backend precision and do not acquire an exactness claim.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_layout_ir.py` and `tests/test_algorithms_support.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 28.

C.1D · Task

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Task`. Reflected implementation `komorebi_math.algorithms.scheduling.Task`. The same runtime object is also available through `komorebi_math.algorithms.Task`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-SCHEDULING`.

Manifest signature (s).

```
(name: 'str', duration: 'float' = 1.0, dependencies: 'tuple[str, ...]' = (), shape_key: 'Hashable | None' = None)
   ↪  -> None
```

Definition. One named task with duration, dependencies, and an optional shape key.

Contract (D, C, H, R, X). Task names must be unique, durations finite and nonnegative, and every dependency must name a supplied task. The dependency graph must be acyclic. Unlimited-concurrency scheduling assigns each task its earliest feasible start and computes critical-path information without imposing an unstated worker limit.

Guarantees (E, P, B, K). The schedule is exact for the finite directed acyclic graph and supplied durations. Runtime is linear in tasks and dependency edges after validation. The result does not model resource contention, communication cost, or preemption unless represented separately.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_scheduling.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · TreeNode

Identity (q, a, t, k). Public research-manifest route `komorebi_math.TreeNode`. Reflected implementation `komorebi_math.algorithms.compiler.TreeNode`. The same runtime object is also available through `komorebi_math.algorithms.TreeNode`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-COMPILER`.

Manifest signature (s).

```
(name: 'str', keep_cost: 'float', keep_error: 'float', split_cost: 'float' = 0.0, children: "tuple['TreeNode',
   ↪  ...]" = ()) -> None
```

Definition. One candidate keep or split decision in a finite compiler tree.

Contract (D, C, H, R, X). A compiler tree is finite, has unique node names, and gives every node a keep cost, keep error, split cost, and child tuple. The Lagrangian compiler minimizes cost plus penalty times error by exact tree dynamic programming. The budget compiler converts each keep error independently to an integer weight and minimizes cost subject to the supplied budget. Principal public operations and properties are `terminal`, `names`.

Guarantees (E, P, B, K). Both compilers return a globally optimal plan for the finite tree and stated objective. Lagrangian compilation is linear in tree size after validation. Budget compilation is pseudo-polynomial in tree size and budget. Error quantization is part of the contract and is not a claim about unmodeled numerical error.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_compiler.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · `WalshHadamardOperator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.WalshHadamardOperator`. Reflected implementation `komorebi_math.algorithms.structured.WalshHadamardOperator`. The same runtime object is also available through `komorebi_math.algorithms.WalshHadamardOperator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-ALG-STRUCTURED`.

Manifest signature (s).

```
(dimension: 'int', normalized: 'bool' = False, dtype_value: 'Any' = <class 'float'>) -> None
```

Definition. Fast Walsh Hadamard transform in power of two dimension.

Contract (D, C, H, R, X). Structured operators expose a common finite `shape`, `dtype`, `apply`, `adjoint`, `materialize`, storage, flop, residual, and solve contract. Dense matrices must be rectangular. Block-diagonal operands must be square and dimension-compatible. Circulant operators are determined by one finite first column. Walsh-Hadamard dimensions must be positive powers of two. Principal public operations and properties are `shape`, `dtype`, `apply`, `materialize`, `adjoint`, `storage_entries`, `flop_count`, `solve`.

Guarantees (E, P, B, K). Applications use the represented structure rather than silently materializing a dense matrix: blockwise execution for direct sums, FFT execution for circulants, and butterfly execution for Walsh-Hadamard transforms. Explicit `materialize` and generic `solve` may allocate dense matrices. Residual certificates are numerical unless the underlying array arithmetic is exact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_structured.py` and `tests/test_algorithms_complexity_benchmarks.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · `assign_discrete_precisions`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.assign_discrete_precisions`. Reflected implementation `komorebi_math.algorithms.precision.assign_discrete_precisions`. The same runtime object is also available through `komorebi_math.algorithms.assign_discrete_precisions`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-PRECISION`.

Manifest signature (s).

```
(options: 'Sequence[Sequence[DTypeChoice]]', budget: 'int') -> 'PrecisionAssignment | None'
```

Definition. Minimize total cost subject to an exact integer error budget.

Contract (D, C, H, R, X). Each precision choice has a finite cost and a nonnegative integer error weight. Every operation must provide at least one option. The assignment routine solves the finite multiple-choice budget problem and returns `None` when no combination satisfies the integer error budget.

Guarantees (E, P, B, K). Dynamic programming is deterministic and exact for the discretized cost and error model. Runtime and memory scale with the number of choices times the integer budget. The result optimizes the supplied model only. It does not infer rounding error or hardware cost that was not encoded in the options.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_precision.py`. The independent verifier for core operators, algorithms,

and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · compile_tree_budget

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compile_tree_budget`. Reflected implementation `komorebi_math.algorithms.compiler.compile_tree_budget`. The same runtime object is also available through `komorebi_math.algorithms.compile_tree_budget`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-COMPILER`.

Manifest signature (s).

```
(root: 'TreeNode', budget: 'int', *, error_unit: 'float' = 1.0) -> 'TreePlan | None'
```

Definition. Minimize cost under additive integer error weights.

Contract (D, C, H, R, X). A compiler tree is finite, has unique node names, and gives every node a keep cost, keep error, split cost, and child tuple. The Lagrangian compiler minimizes cost plus penalty times error by exact tree dynamic programming. The budget compiler converts each keep error independently to an integer weight and minimizes cost subject to the supplied budget.

Guarantees (E, P, B, K). Both compilers return a globally optimal plan for the finite tree and stated objective. Lagrangian compilation is linear in tree size after validation. Budget compilation is pseudo-polynomial in tree size and budget. Error quantization is part of the contract and is not a claim about unmodeled numerical error.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_compiler.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · compile_tree_lagrangian

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compile_tree_lagrangian`. Reflected implementation `komorebi_math.algorithms.compiler.compile_tree_lagrangian`. The same runtime object is also available through `komorebi_math.algorithms.compile_tree_lagrangian`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-COMPILER`.

Manifest signature (s).

```
(root: 'TreeNode', penalty: 'float') -> 'TreePlan'
```

Definition. Return the exact minimizer of cost plus penalty times error.

Contract (D, C, H, R, X). A compiler tree is finite, has unique node names, and gives every node a keep cost, keep error, split cost, and child tuple. The Lagrangian compiler minimizes cost plus penalty times error by exact tree dynamic programming. The budget compiler converts each keep error independently to an integer weight and minimizes cost subject to the supplied budget.

Guarantees (E, P, B, K). Both compilers return a globally optimal plan for the finite tree and stated objective. Lagrangian compilation is linear in tree size after validation. Budget compilation is pseudo-polynomial in tree size and budget. Error quantization is part of the contract and is not a claim about unmodeled numerical error.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_compiler.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · conjugate_gradient

Identity (q, a, t, k). Public research-manifest route `komorebi_math.conjugate_gradient`. Reflected implementation `komorebi_math.algorithms.krylov.conjugate_gradient`. The same runtime object is also available through `komorebi_math.algorithms.conjugate_gradient`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-KRYLOV`.

Manifest signature (s).

```
(apply: 'Apply', right_hand_side: 'Any', *, precondition: 'Apply | None' = None, initial: 'Any | None' = None,
    ↪ relative_tolerance: 'float' = 1e-10, absolute_tolerance: 'float' = 0.0, max_iterations: 'int | None' = None,
    ↪ curvature_tolerance: 'float' = 1e-14) -> 'ConjugateGradientResult'
```

Definition. Solve a declared Hermitian positive definite system by CG.

Contract (D, C, H, R, X). Conjugate gradient accepts a finite vector, a linear application callable, and an optional preconditioner. Tolerances and iteration limits must be finite and nonnegative. The method assumes a Hermitian positive-definite operator, checks curvature and residuals during execution, and records convergence, breakdown, or iteration exhaustion explicitly.

Guarantees (E, P, B, K). Each iteration performs a bounded number of operator applications and vector operations. Storage is linear in vector dimension. Convergence depends on the declared positive-definite model and conditioning. A small computed residual is numerical evidence, not an exact solution certificate.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_krylov.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

C.1D · discover_block_diagonal_low_rank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.discover_block_diagonal_low_rank`. Reflected implementation `komorebi_math.algorithms.discovery.discover_block_diagonal_low_rank`. The same runtime object is also available through `komorebi_math.algorithms.discover_block_diagonal_low_rank`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-DISCOVERY`.

Manifest signature (s).

```
(matrix: 'Any', layout: 'PacketLayout', rank: 'int', *, tolerance: 'float' = 1e-10) -> 'BDLRDiscoveryResult'
```

Definition. Project onto a fixed block diagonal part and truncate its residual SVD.

Contract (D, C, H, R, X). Discovery routines operate inside a fixed packet layout. Support discovery thresholds observed block norms using absolute and relative tolerances. Block-diagonal low-rank discovery projects onto the declared diagonal layout, computes a residual singular-value decomposition, and truncates to the requested rank.

Guarantees (E, P, B, K). Outputs are deterministic for fixed numerical inputs and backend routines. They are heuristic model selections accompanied by measured residuals, not proofs that the discovered support or rank is unique or optimal outside the stated projection problem. Dense singular-value decomposition can dominate runtime and memory.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_discovery_gpu.py` and `tests/test_algorithms_support.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 28 through 30.

C.1D · discover_packet_support

Identity (q, a, t, k). Public research-manifest route `komorebi_math.discover_packet_support`. Reflected implementation `komorebi_math.algorithms.discovery.discover_packet_support`. The same runtime object is also available through `komorebi_math.algorithms.discover_packet_support`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-DISCOVERY`.

Manifest signature (s).

```
(matrix: 'Any', layout: 'PacketLayout', *, absolute_tolerance: 'float' = 0.0, relative_tolerance: 'float' = 1e-12)
   ↪  -> 'SupportDiscoveryResult'
```

Definition. Discover a heuristic block support inside a fixed packet layout.

Contract (D, C, H, R, X). Discovery routines operate inside a fixed packet layout. Support discovery thresholds observed block norms using absolute and relative tolerances. Block-diagonal low-rank discovery projects onto the declared diagonal layout, computes a residual singular-value decomposition, and truncates to the requested rank.

Guarantees (E, P, B, K). Outputs are deterministic for fixed numerical inputs and backend routines. They are heuristic model selections accompanied by measured residuals, not proofs that the discovered support or rank is unique or optimal outside the stated projection problem. Dense singular-value decomposition can dominate runtime and memory.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_discovery_gpu.py` and `tests/test_algorithms_support.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 28 through 30.

C.1D · recompress_factors

Identity (q, a, t, k). Public research-manifest route `komorebi_math.recompress_factors`. Reflected implementation `komorebi_math.algorithms.low_rank.recompress_factors`. The same runtime object is also available through `komorebi_math.algorithms.recompress_factors`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-LOW-RANK`.

Manifest signature (s).

```
(left: 'Any', right: 'Any', rank: 'int', *, tolerance: 'float' = 1e-10) -> 'RecompressionResult'
```

Definition. Recompress a two factor product through an identity small core.

Contract (D, C, H, R, X). Low-rank factors must be two-dimensional, share a common rank, and represent `left @ right.conj().T`. A block-diagonal low-rank operator requires a square diagonal part and a correction of matching shape. Recompression validates the requested rank and tolerance, forms a small core, and truncates through singular-value decomposition.

Guarantees (E, P, B, K). Application and storage scale with factor rank rather than the full dense matrix when the rank is small. Recompression and Woodbury-style solves are numerical and depend on singular-value and conditioning thresholds. Materialization remains available but loses the storage advantage. Rank bounds are finite upper bounds, not minimum-rank proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_low_rank.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 29.

C.1D · schedule_unlimited

Identity (q, a, t, k). Public research-manifest route `komorebi_math.schedule_unlimited`. Reflected implementation `komorebi_math.algorithms.scheduling.schedule_unlimited`. The same runtime object is also available through `komorebi_math.algorithms.schedule_unlimited`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-ALG-SCHEDULING`.

Manifest signature (s).

```
(tasks: 'Sequence[Task]') -> 'TaskSchedule'
```

Definition. Return the earliest start schedule under unlimited concurrency.

Contract (D, C, H, R, X). Task names must be unique, durations finite and nonnegative, and every dependency must name a supplied task. The dependency graph must be acyclic. Unlimited-concurrency scheduling assigns each task its earliest feasible start and computes critical-path information without imposing an unstated worker limit.

Guarantees (E, P, B, K). The schedule is exact for the finite directed acyclic graph and supplied durations. Runtime is linear in tasks and dependency edges after validation. The result does not model resource contention, communication cost, or preemption unless represented separately.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_algorithms_scheduling.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapter 30.

Exact integration (38 cards).

C.1D · AtomicIntegratedDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AtomicIntegratedDerivativeProvider`. Reflected implementation `komorebi_math.integration.adapters.AtomicIntegratedDerivativeProvider`. The same runtime object is also available through `komorebi_math.integration.AtomicIntegratedDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-ADAPTER`.

Manifest signature (s).

```
(providers: 'Sequence[Any]', weights: 'Sequence[int | Fraction | float]', name: 'str' = 'atomic integrated
    ↪ derivative provider') -> None
```

Definition. A fixed finite weighted sum of compatible derivative providers.

Contract (D, C, H, R, X). Adapters convert finite formal-series or polynomial-family coordinates into `ExactPolynomial`, integrate through the ordinary measure interface, or combine compatible derivative providers with fixed scalar weights. Degree truncation must be explicit. Analysis-synthesis integration checks compare physical and coefficient-side finite sums under one declared system and atomic measure. Principal public operations and properties are `supports_order`, `value`, `derivative`, `certificate`.

Guarantees (E, P, B, K). Conversions are exact when coefficients, family data, and measures are exact. Truncation is reported rather than hidden. Provider sums preserve the weakest child certificate status. The atomic derivative adapter deliberately excludes parameter-dependent measure derivatives, which would require an additional term.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · AtomicMeasure

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AtomicMeasure`. Reflected implementation `komorebi_math.integration.measures.AtomicMeasure`. The same runtime object is also available through `komorebi_math.integration.AtomicMeasure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-MEASURE`.

Manifest signature (s).

```
(points: 'Iterable[Any]', weights: 'Iterable[Any]', *, name: 'str' = 'atomic measure') -> 'None'
```

Definition. A finite positive atomic measure with exact or floating-point data.

Contract (D, C, H, R, X). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions. Principal public operations and properties are `atom_count`, `mass`, `moment`, `normalized`, `coalesced`, `certificate`.

Guarantees (E, P, B, K). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · CompositeSimpson

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CompositeSimpson`. Reflected implementation `komorebi_math.integration.quadrature.CompositeSimpson`. The same runtime object is also available through `komorebi_math.integration.CompositeSimpson`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(subintervals: 'int' = 64, derivative_bound: 'DerivativeBound | None' = None, max_evaluations: 'int' = 1000000) ->
    ↪ None
```

Definition. Composite Simpson quadrature for bounded interval factors.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records. Principal public operations and properties are `without_derivative_bound`.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact

signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · DerivativeBound

Identity (q, a, t, k). Public research-manifest route `komorebi_math.DerivativeBound`. Reflected implementation `komorebi_math.integration.quadrature.DerivativeBound`. The same runtime object is also available through `komorebi_math.integration.DerivativeBound`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(order: 'int', bound: 'Fraction | float', certificate: 'Certificate', description: 'str' = 'derivative supremum
    ↪ bound', polynomial: 'ExactPolynomial | None' = None, interval: 'tuple[Fraction, Fraction] | None' = None) ->
    ↪ None
```

Definition. A declared bound `sup |f^(order)| <= bound` with its own proof status.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records. Principal public operations and properties are `guarantee`, `applies_to`, `assumed`.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · ErrorGuarantee

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ErrorGuarantee`. Reflected implementation `komorebi_math.integration.quadrature.ErrorGuarantee`. The same runtime object is also available through `komorebi_math.integration.ErrorGuarantee`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(*values)
```

Definition. Strength of an integration error statement.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource

paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · ExactAffineMap

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactAffineMap`. Reflected implementation `komorebi_math.integration.measures.ExactAffineMap`. The same runtime object is also available through `komorebi_math.integration.ExactAffineMap`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-MEASURE`.

Manifest signature (s).

```
(matrix: 'Iterable[Iterable[Rational]]', shift: 'Iterable[Rational]', *, name: 'str' = 'exact affine map') ->
   ↪ 'None'
```

Definition. An exact affine map `x -> matrix*x + shift` over `Q`.

Contract (D, C, H, R, X). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions. Principal public operations and properties are `identity`, `source_dimension`, `target_dimension`, `square`, `apply_point`, `then`, `pullback`, `determinant`, `certificate`.

Guarantees (E, P, B, K). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · ExactPolynomial

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactPolynomial`. Reflected implementation `komorebi_math.integration.polynomial.ExactPolynomial`. The same runtime object is also available through `komorebi_math.integration.ExactPolynomial`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-POLYNOMIAL`.

Manifest signature (s).

```
(dimension: 'int', terms: 'Mapping[Sequence[int], Rational] | Iterable[tuple[Sequence[int], Rational]]') -> 'None'
```

Definition. A sparse polynomial `sum_exponent c_exponent x^exponent` over `Q`.

Contract (D, C, H, R, X). An exact polynomial has a positive finite dimension and a sparse mapping from nonnegative exponent tuples to integer or `Fraction` coefficients. Construction combines duplicate exponents and removes zeros. Arithmetic, derivatives, antiderivatives, affine pullback, evaluation, and variable integration validate dimensions and enforce explicit term budgets where expansion can grow. Principal public operations and properties are `zero`, `constant`, `monomial`, `univariate`, `degree`, `degrees`, `term_count`, `coefficient`, `evaluate`, `add`, `subtract`, `scale`, `multiply`, `power`, `derivative`, `antiderivative`.

Guarantees (E, P, B, K). All polynomial coefficients and exact evaluations use `Fraction` arithmetic. Sparse costs scale with the number of terms, while multiplication, powers, and affine pullback can expand combinatorially. Certificates cover the finite polynomial representation and exact operations, not convergence of an infinite series.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `ExactQuadratureRule`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ExactQuadratureRule`. Reflected implementation `komorebi_math.integration.rules.ExactQuadratureRule`. The same runtime object is also available through `komorebi_math.integration.ExactQuadratureRule`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-RULE`.

Manifest signature (s).

```
(points: 'Iterable[Any]', weights: 'Iterable[Any]', *, name: 'str' = 'exact quadrature rule') -> 'None'
```

Definition. A quadrature functional with rational nodes and signed rational weights.

Contract (D, C, H, R, X). A quadrature rule is a finite linear functional with nodes and weights of equal nonzero length. General rules may use signed or floating weights. Exact rules require rational nodes and weights. Moment comparison determines the tested degree of exactness, and tensor products preserve the stated node ordering and finite dimensionality.

Guarantees (E, P, B, K). Exact rules integrate supported exact polynomials through rational arithmetic. Numerical rules preserve measured residuals and do not claim exactness beyond tested moments. Tensor-product node count multiplies across factors and can grow exponentially with dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `IntegralIdentity`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.IntegralIdentity`. Reflected implementation `komorebi_math.integration.identities.IntegralIdentity`. The same runtime object is also available through `komorebi_math.integration.IntegralIdentity`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-IDENTITY`.

Manifest signature (s).

```
(name: 'str', left: 'Any', right: 'Any', certificate: 'Certificate') -> None
```

Definition. Two computed sides of an integral identity and their certificate.

Contract (D, C, H, R, X). Identity constructors compute both sides from exact polynomials, finite measures, and exact affine maps, then compare them under the stated theorem. Fundamental-theorem and integration-by-parts identities require one-dimensional interval measures. Fubini identities require product measures and explicit variable orders. The all-orders routine enforces a factorial dimension budget. Principal public operations and properties are `valid`, `require`.

Guarantees (E, P, B, K). With exact inputs, both sides and equality checks use rational arithmetic and the certificate is exact. Callable pushforward assumptions are not silently discharged. Enumerating every Fubini order grows factorially, so dimensions above the explicit limit are rejected.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms,

and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `IntegralResult`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.IntegralResult`. Reflected implementation `komorebi_math.integration.quadrature.IntegralResult`. The same runtime object is also available through `komorebi_math.integration.IntegralResult`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (`s`).

```
(value: 'Any', certificate: 'Certificate', error: 'IntegrationError', method: 'str', evaluations: 'int') -> None
```

Definition. An integral value with method, evaluation count, certificate, and error.

Contract (`D, C, H, R, X`). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records. Principal public operations and properties are `valid`, `exact`, `require`.

Guarantees (`E, P, B, K`). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `IntegrationError`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.IntegrationError`. Reflected implementation `komorebi_math.integration.quadrature.IntegrationError`. The same runtime object is also available through `komorebi_math.integration.IntegrationError`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (`s`).

```
(absolute_bound: 'Fraction | float | None', guarantee: 'ErrorGuarantee', sources: 'tuple[str, ...]' = ()) -> None
```

Definition. One absolute error statement attached to an integral result.

Contract (`D, C, H, R, X`). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records. Principal public operations and properties are `rigorous`, `exact`.

Guarantees (`E, P, B, K`). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms,

and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `IntervalMeasure`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.IntervalMeasure`. Reflected implementation `komorebi_math.integration.measures.IntervalMeasure`. The same runtime object is also available through `komorebi_math.integration.IntervalMeasure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-MEASURE`.

Manifest signature (`s`).

```
(lower: 'Any', upper: 'Any', *, density: 'Any' = 1, name: 'str' = 'interval measure') -> 'None'
```

Definition. Constant-density Lebesgue measure on one bounded interval.

Contract (`D, C, H, R, X`). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions. Principal public operations and properties are `structurally_zero`, `mass`, `moment`, `normalized`, `pushforward_affine`, `certificate`.

Guarantees (`E, P, B, K`). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `Measure`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.Measure`. Reflected implementation `komorebi_math.integration.measures.Measure`. The same runtime object is also available through `komorebi_math.integration.Measure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-MEASURE`.

Manifest signature (`s`).

```
(*args, **kwargs)
```

Definition. Protocol for finite measures usable by `integrate`.

Contract (`D, C, H, R, X`). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions. Principal public operations and properties are `mass`, `moment`, `certificate`.

Guarantees (`E, P, B, K`). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · PolynomialIntegrationCovector

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolynomialIntegrationCovector`. Reflected implementation `komorebi_math.integration.coordinates.PolynomialIntegrationCovector`. The same runtime object is also available through `komorebi_math.integration.PolynomialIntegrationCovector`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-COORDINATE`.

Manifest signature (s).

```
(family: 'str', degree: 'int', measure: 'IntervalMeasure', weights: 'tuple[Fraction, ...]', basis_witness:
    ↪ 'tuple[tuple[Fraction, ...], ...] | None' = None) -> None
```

Definition. The integral functional in one finite polynomial basis.

Contract (D, C, H, R, X). A polynomial integration covector stores the exact interval moments of one finite polynomial basis. Construction validates family, degree, interval measure, and basis witness. Coordinate identities compare the integration covector with derivative, endpoint-evaluation, or basis-change matrices using exact finite linear algebra. Principal public operations and properties are `basis_verified`, `apply`, `certificate`.

Guarantees (E, P, B, K). A covector built by `polynomial_integration_covector` carries replayable basis provenance and exact rational weights. A manually supplied covector without a basis witness remains a finite linear functional but its family interpretation is conditional. Dense basis conversion can require cubic exact matrix work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapters 64 and 68.

C.1D · ProductMeasure

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ProductMeasure`. Reflected implementation `komorebi_math.integration.measures.ProductMeasure`. The same runtime object is also available through `komorebi_math.integration.ProductMeasure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-MEASURE`.

Manifest signature (s).

```
(factors: 'Iterable[Measure]', *, name: 'str' = 'product measure') -> 'None'
```

Definition. Finite product of typed component measures.

Contract (D, C, H, R, X). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions. Principal public operations and properties are `mass`, `moment`, `certificate`.

Guarantees (E, P, B, K). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results,

and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `PushforwardMeasure`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PushforwardMeasure`. Reflected implementation `komorebi_math.integration.measures.PushforwardMeasure`. The same runtime object is also available through `komorebi_math.integration.PushforwardMeasure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-MEASURE`.

Manifest signature (s).

```
(base: 'Measure', mapping: 'ExactAffineMap | Callable[[Any], Any]', *, target_dimension: 'int | None' = None, name:
   ↪  'str' = 'pushforward measure') -> 'None'
```

Definition. The pushforward `mapping_# base`.

Contract (D, C, H, R, X). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions. Principal public operations and properties are `mass`, `map_point`, `materialize_atomic`, `moment`, `certificate`.

Guarantees (E, P, B, K). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `QuadratureExactness`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.QuadratureExactness`. Reflected implementation `komorebi_math.integration.rules.QuadratureExactness`. The same runtime object is also available through `komorebi_math.integration.QuadratureExactness`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-RULE`.

Manifest signature (s).

```
(degree: 'int', max_tested_degree: 'int', exact: 'bool', certificate: 'Certificate') -> None
```

Definition. Moment comparison between a quadrature functional and one measure.

Contract (D, C, H, R, X). A quadrature rule is a finite linear functional with nodes and weights of equal nonzero length. General rules may use signed or floating weights. Exact rules require rational nodes and weights. Moment comparison determines the tested degree of exactness, and tensor products preserve the stated node ordering and finite dimensionality.

Guarantees (E, P, B, K). Exact rules integrate supported exact polynomials through rational arithmetic. Numerical rules preserve measured residuals and do not claim exactness beyond tested moments. Tensor-product node count multiplies across factors and can grow exponentially with dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `QuadratureRule`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.QuadratureRule`. Reflected implementation `komorebi_math.integration.rules.QuadratureRule`. The same runtime object is also available through `komorebi_math.integration.QuadratureRule`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1D-INT-RULE`.

Manifest signature (s).

```
(points: 'Iterable[Any]', weights: 'Iterable[Any]', *, name: 'str' = 'quadrature rule', _require_exact: 'bool' =
   ↪ False) -> 'None'
```

Definition. A finite linear functional `Q[f]=sum_i w_i f(x_i)`.

Contract (D, C, H, R, X). A quadrature rule is a finite linear functional with nodes and weights of equal nonzero length. General rules may use signed or floating weights. Exact rules require rational nodes and weights. Moment comparison determines the tested degree of exactness, and tensor products preserve the stated node ordering and finite dimensionality. Principal public operations and properties are `node_count`, `exact_data`, `positive`, `apply`, `moment`, `integrate_polynomial`, `tensor_product`, `as_atomic_measure`, `degree_of_exactness`, `certify_polynomial_integral`, `certificate`.

Guarantees (E, P, B, K). Exact rules integrate supported exact polynomials through rational arithmetic. Numerical rules preserve measured residuals and do not claim exactness beyond tested moments. Tensor-product node count multiplies across factors and can grow exponentially with dimension.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `affine_interval_change_of_variables`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.affine_interval_change_of_variables`. Reflected implementation `komorebi_math.integration.identities.affine_interval_change_of_variables`. The same runtime object is also available through `komorebi_math.integration.affine_interval_change_of_variables`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-IDENTITY`.

Manifest signature (s).

```
(polynomial: 'ExactPolynomial', base: 'IntervalMeasure', mapping: 'ExactAffineMap') -> 'IntegralIdentity'
```

Definition. Certify the one-dimensional affine Jacobian density law exactly.

Contract (D, C, H, R, X). Identity constructors compute both sides from exact polynomials, finite measures, and exact affine maps, then compare them under the stated theorem. Fundamental-theorem and integration-by-parts identities require one-dimensional interval measures. Fubini identities require product measures and explicit variable orders. The all-orders routine enforces a factorial dimension budget.

Guarantees (E, P, B, K). With exact inputs, both sides and equality checks use rational arithmetic and the certificate is exact. Callable pushforward assumptions are not silently discharged. Enumerating every Fubini order grows factorially, so dimensions above the explicit limit are rejected.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `all_fubini_orders`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.all_fubini_orders`. Reflected implementation `komorebi_math.integration.identities.all_fubini_orders`. The same runtime object is also available through `komorebi_math.integration.all_fubini_orders`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-IDENTITY`.

Manifest signature (s).

```
(polynomial: 'ExactPolynomial', measure: 'ProductMeasure', *, max_dimensions: 'int' = 7) ->
    ↪ 'tuple[IntegralIdentity, ...]'
```

Definition. Certify every variable order within an explicit factorial budget.

Contract (D, C, H, R, X). Identity constructors compute both sides from exact polynomials, finite measures, and exact affine maps, then compare them under the stated theorem. Fundamental-theorem and integration-by-parts identities require one-dimensional interval measures. Fubini identities require product measures and explicit variable orders. The all-orders routine enforces a factorial dimension budget.

Guarantees (E, P, B, K). With exact inputs, both sides and equality checks use rational arithmetic and the certificate is exact. Callable pushforward assumptions are not silently discharged. Enumerating every Fubini order grows factorially, so dimensions above the explicit limit are rejected.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `analysis_synthesis_integration_certificate`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.analysis_synthesis_integration_certificate`. Reflected implementation `komorebi_math.integration.adapters.analysis_synthesis_integration_certificate`. The same runtime object is also available through `komorebi_math.integration.analysis_synthesis_integration_certificate`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-ADAPTER`.

Manifest signature (s).

```
(system: 'AnalysisSynthesisSystem', measure: 'AtomicMeasure', physical_values: 'Sequence[Any]', *, tolerance:
    ↪ 'float' = 1e-10) -> 'Certificate'
```

Definition. Check that a fixed analysis/synthesis system commutes with finite integration.

Contract (D, C, H, R, X). Adapters convert finite formal-series or polynomial-family coordinates into `ExactPolynomial`, integrate through the ordinary measure interface, or combine compatible derivative providers with fixed scalar weights. Degree truncation must be explicit. Analysis-synthesis integration checks compare physical and coefficient-side finite sums under one declared system and atomic measure.

Guarantees (E, P, B, K). Conversions are exact when coefficients, family data, and measures are exact. Truncation is reported rather than hidden. Provider sums preserve the weakest child certificate status. The atomic derivative adapter deliberately excludes parameter-dependent measure derivatives, which would require an additional term.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · coordinate_fundamental_theorem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinate_fundamental_theorem`. Reflected implementation `komorebi_math.integration.coordinates.coordinate_fundamental_theorem`. The same runtime object is also available through `komorebi_math.integration.coordinate_fundamental_theorem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-COORDINATE`.

Manifest signature (s).

```
(family: 'PolynomialFamily', degree: 'int', measure: 'IntervalMeasure') -> 'IntegralIdentity'
```

Definition. Certify `ell D = rho(ev_b - ev_a)` in the declared basis.

Contract (D, C, H, R, X). A polynomial integration covector stores the exact interval moments of one finite polynomial basis. Construction validates family, degree, interval measure, and basis witness. Coordinate identities compare the integration covector with derivative, endpoint-evaluation, or basis-change matrices using exact finite linear algebra.

Guarantees (E, P, B, K). A covector built by `polynomial_integration_covector` carries replayable basis provenance and exact rational weights. A manually supplied covector without a basis witness remains a finite linear functional but its family interpretation is conditional. Dense basis conversion can require cubic exact matrix work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapters 64 and 68.

C.1D · coordinate_transport_identity

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinate_transport_identity`. Reflected implementation `komorebi_math.integration.coordinates.coordinate_transport_identity`. The same runtime object is also available through `komorebi_math.integration.coordinate_transport_identity`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-COORDINATE`.

Manifest signature (s).

```
(source: 'PolynomialFamily', target: 'PolynomialFamily', degree: 'int', measure: 'IntervalMeasure') ->
   ↪ 'IntegralIdentity'
```

Definition. Certify contragredient transport `ell_target C = ell_source`.

Contract (D, C, H, R, X). A polynomial integration covector stores the exact interval moments of one finite polynomial basis. Construction validates family, degree, interval measure, and basis witness. Coordinate identities compare the integration covector with derivative, endpoint-evaluation, or basis-change matrices using exact finite linear algebra.

Guarantees (E, P, B, K). A covector built by `polynomial_integration_covector` carries replayable basis provenance and exact rational weights. A manually supplied covector without a basis witness remains a finite linear functional but its family interpretation is conditional. Dense basis conversion can require cubic exact matrix work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `fundamental_theorem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.fundamental_theorem`. Reflected implementation `komorebi_math.integration.identities.fundamental_theorem`. The same runtime object is also available through `komorebi_math.integration.fundamental_theorem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-IDENTITY`.

Manifest signature (s).

```
(polynomial: 'ExactPolynomial', measure: 'IntervalMeasure') -> 'IntegralIdentity'
```

Definition. Certify `integral p d(rho x) = rho(F(b)-F(a))` exactly.

Contract (D, C, H, R, X). Identity constructors compute both sides from exact polynomials, finite measures, and exact affine maps, then compare them under the stated theorem. Fundamental-theorem and integration-by-parts identities require one-dimensional interval measures. Fubini identities require product measures and explicit variable orders. The all-orders routine enforces a factorial dimension budget.

Guarantees (E, P, B, K). With exact inputs, both sides and equality checks use rational arithmetic and the certificate is exact. Callable pushforward assumptions are not silently discharged. Enumerating every Fubini order grows factorially, so dimensions above the explicit limit are rejected.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · integrate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.integrate`. Reflected implementation `komorebi_math.integration.quadrature.integrate`. The same runtime object is also available through `komorebi_math.integration.integrate`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(integrand: 'ExactPolynomial | Callable[[Any], Any]', measure: 'Measure', *, provider: 'CompositeSimpson | None' =
    ↪ None) -> 'IntegralResult'
```

Definition. Integrate an exact polynomial or callable against a finite measure.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · integrate_derivative_provider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.integrate_derivative_provider`. Reflected implementation `komorebi_math.integration.quadrature.integrate_derivative_provider`. The same runtime object is also available through `komorebi_math.integration.integrate_derivative_provider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(provider: 'Any', measure: 'Measure', *, quadrature: 'CompositeSimpson | None' = None) -> 'IntegralResult'
```

Definition. Integrate the value map of an existing finite derivative provider.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `integrate_formal_series`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.integrate_formal_series`. Reflected implementation `komorebi_math.integration.adapters.integrate_formal_series`. The same runtime object is also available through `komorebi_math.integration.integrate_formal_series`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-ADAPTER`.

Manifest signature (s).

```
(series: 'FormalSeries', measure: 'Measure', *, degree: 'int | None' = None) -> 'IntegralResult'
```

Definition. Convert a finite truncation of a normalized formal series to an exact polynomial and integrate it against a finite measure.

Contract (D, C, H, R, X). Adapters convert finite formal-series or polynomial-family coordinates into `ExactPolynomial`, integrate through the ordinary measure interface, or combine compatible derivative providers with fixed scalar weights. Degree truncation must be explicit. Analysis-synthesis integration checks compare physical and coefficient-side finite sums under one declared system and atomic measure.

Guarantees (E, P, B, K). Conversions are exact when coefficients, family data, and measures are exact. Truncation is reported rather than hidden. Provider sums preserve the weakest child certificate status. The atomic derivative adapter deliberately excludes parameter-dependent measure derivatives, which would require an additional term.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `integrate_polynomial_coordinates`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.integrate_polynomial_coordinates`. Reflected implementation `komorebi_math.integration.adapters.integrate_polynomial_coordinates`. The same runtime object is also available through `komorebi_math.integration.integrate_polynomial_coordinates`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-ADAPTER`.

Manifest signature (s).

```
(family: 'PolynomialFamily', coefficients: 'Iterable[Rational]', measure: 'Measure') -> 'IntegralResult'
```

Definition. Convert coefficients in an exact polynomial family to ordinary polynomial form and integrate the result.

Contract (D, C, H, R, X). Adapters convert finite formal-series or polynomial-family coordinates into `ExactPolynomial`, integrate through the ordinary measure interface, or combine compatible derivative providers with fixed scalar weights. Degree truncation must be explicit. Analysis-synthesis integration checks compare physical and coefficient-side finite sums under one declared system and atomic measure.

Guarantees (E, P, B, K). Conversions are exact when coefficients, family data, and measures are exact. Truncation is reported rather than hidden. Provider sums preserve the weakest child certificate status. The atomic derivative adapter deliberately excludes parameter-dependent measure derivatives, which would require an additional term.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `integrate_polynomial_oriented`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.integrate_polynomial_oriented`. Reflected implementation `komorebi_math.integration.quadrature.integrate_polynomial_oriented`. The same runtime object is also available through `komorebi_math.integration.integrate_polynomial_oriented`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(polynomial: 'ExactPolynomial', lower: 'int | Fraction', upper: 'int | Fraction', *, density: 'int | Fraction' = 1)
   ↪  -> 'IntegralResult'
```

Definition. Integrate over oriented bounds without mislabeling orientation as a measure.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `integration_by_parts`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.integration_by_parts`. Reflected implementation `komorebi_math.integration.identities.integration_by_parts`. The same runtime object is also available through `komorebi_math.integration.integration_by_parts`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-IDENTITY`.

Manifest signature (s).

```
(left_factor: 'ExactPolynomial', right_factor: 'ExactPolynomial', measure: 'IntervalMeasure') -> 'IntegralIdentity'
```

Definition. Certify `int u v' = rho[uv]_a^b - int u' v` exactly.

Contract (D, C, H, R, X). Identity constructors compute both sides from exact polynomials, finite measures, and exact affine maps, then compare them under the stated theorem. Fundamental-theorem and integration-by-parts identities require one-dimensional interval measures. Fubini identities require product measures and explicit variable orders. The all-orders routine enforces a factorial dimension budget.

Guarantees (E, P, B, K). With exact inputs, both sides and equality checks use rational arithmetic and the certificate is exact. Callable pushforward assumptions are not silently discharged. Enumerating every Fubini order grows factorially, so dimensions above the explicit limit are rejected.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `polynomial_derivative_bound`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.polynomial_derivative_bound`. Reflected implementation `komorebi_math.integration.quadrature.polynomial_derivative_bound`. The same runtime object is also available through `komorebi_math.integration.polynomial_derivative_bound`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-QUADRATURE`.

Manifest signature (s).

```
(polynomial: 'ExactPolynomial', measure: 'IntervalMeasure', *, order: 'int' = 4) -> 'DerivativeBound'
```

Definition. Create a rigorous coefficient-triangle derivative bound.

Contract (D, C, H, R, X). Integration accepts an exact polynomial or a callable and one finite measure. Exact polynomials use moments when available. Atomic callables use finite weighted sums. Interval callables use composite Simpson quadrature with an even positive subinterval count and evaluation budget. Derivative bounds, error guarantees, orientation, and failure status remain explicit in the returned records.

Guarantees (E, P, B, K). Exact polynomial paths return exact values when all required moments are exact. Simpson bounds are rigorous only when a valid fourth-derivative bound applies to the interval. Otherwise the error status is conditional, estimated, or unknown as recorded. Numerical evaluation count is finite and bounded by the provider budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `polynomial_from_family_coordinates`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.polynomial_from_family_coordinates`. Reflected implementation `komorebi_math.integration.adapters.polynomial_from_family_coordinates`. The same runtime object is also available through `komorebi_math.integration.polynomial_from_family_coordinates`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-ADAPTER`.

Manifest signature (s).

```
(family: 'PolynomialFamily', coefficients: 'Iterable[Rational]') -> 'ExactPolynomial'
```

Definition. Convert finite coordinates in any exact polynomial family to a polynomial.

Contract (D, C, H, R, X). Adapters convert finite formal-series or polynomial-family coordinates into `ExactPolynomial`, integrate through the ordinary measure interface, or combine compatible derivative providers with fixed scalar weights. Degree truncation must be explicit. Analysis-synthesis integration checks compare physical and coefficient-side finite sums under one declared system and atomic measure.

Guarantees (E, P, B, K). Conversions are exact when coefficients, family data, and measures are exact. Truncation is reported rather than hidden. Provider sums preserve the weakest child certificate status. The atomic derivative adapter deliberately excludes parameter-dependent measure derivatives, which would require an additional term.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `polynomial_from_formal_series`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.polynomial_from_formal_series`. Reflected implementation `komorebi_math.integration.adapters.polynomial_from_formal_series`. The same runtime object is also available through `komorebi_math.integration.polynomial_from_formal_series`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-ADAPTER`.

Manifest signature (s).

```
(series: 'FormalSeries', *, degree: 'int | None' = None) -> 'ExactPolynomial'
```

Definition. Convert one finite normalized formal series to ordinary polynomial form.

Contract (D, C, H, R, X). Adapters convert finite formal-series or polynomial-family coordinates into `ExactPolynomial`, integrate through the ordinary measure interface, or combine compatible derivative providers with fixed scalar weights. Degree truncation must be explicit. Analysis-synthesis integration checks compare physical and coefficient-side finite sums under one declared system and atomic measure.

Guarantees (E, P, B, K). Conversions are exact when coefficients, family data, and measures are exact. Truncation is reported rather than hidden. Provider sums preserve the weakest child certificate status. The atomic derivative adapter deliberately excludes parameter-dependent measure derivatives, which would require an additional term.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `polynomial_integration_covector`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.polynomial_integration_covector`. Reflected implementation `komorebi_math.integration.coordinates.polynomial_integration_covector`. The same runtime object is also available through `komorebi_math.integration.polynomial_integration_covector`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-COORDINATE`.

Manifest signature (s).

```
(family: 'PolynomialFamily', degree: 'int', measure: 'IntervalMeasure') -> 'PolynomialIntegrationCovector'
```

Definition. Construct the exact interval-integration functional in a declared finite polynomial basis.

Contract (D, C, H, R, X). A polynomial integration covector stores the exact interval moments of one finite polynomial basis. Construction validates family, degree, interval measure, and basis witness. Coordinate identities compare the integration covector with derivative, endpoint-evaluation, or basis-change matrices using exact finite linear algebra.

Guarantees (E, P, B, K). A covector built by `polynomial_integration_covector` carries replayable basis provenance and exact rational weights. A manually supplied covector without a basis witness remains a finite linear functional but its family interpretation is conditional. Dense basis conversion can require cubic exact matrix work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py` and `tests/test_coordinates_polynomials.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapters 64 and 68.

C.1D · `product_measure`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.product_measure`. Reflected implementation `komorebi_math.integration.measures.product_measure`. The same runtime object is also available through `komorebi_math.integration.product_measure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-MEASURE`.

Manifest signature (s).

```
(*factors: 'Measure', name: 'str' = 'product measure') -> 'ProductMeasure'
```

Definition. Construct a finite product measure from the supplied factors.

Contract (D, C, H, R, X). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions.

Guarantees (E, P, B, K). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `pushforward_identity`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.pushforward_identity`. Reflected implementation `komorebi_math.integration.identities.pushforward_identity`. The same runtime object is also available through `komorebi_math.integration.pushforward_identity`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-IDENTITY`.

Manifest signature (s).

```
(polynomial: 'ExactPolynomial', base: 'Measure', mapping: 'ExactAffineMap') -> 'IntegralIdentity'
```

Definition. Certify `int f d(mapping_# mu) = int (f o mapping) dmu`.

Contract (D, C, H, R, X). Identity constructors compute both sides from exact polynomials, finite measures, and exact affine maps, then compare them under the stated theorem. Fundamental-theorem and integration-by-parts identities require one-dimensional interval measures. Fubini identities require product measures and explicit variable orders. The all-orders routine enforces a factorial dimension budget.

Guarantees (E, P, B, K). With exact inputs, both sides and equality checks use rational arithmetic and the certificate is exact. Callable pushforward assumptions are not silently discharged. Enumerating every Fubini order grows factorially, so dimensions above the explicit limit are rejected.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1D · `pushforward_measure`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.pushforward_measure`. Reflected implementation `komorebi_math.integration.measures.pushforward_measure`. The same runtime object is also available through `komorebi_math.integration.pushforward_measure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This card does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1D-INT-MEASURE`.

Manifest signature (s).

```
(base: 'Measure', mapping: 'ExactAffineMap | Callable[[Any], Any]', *, target_dimension: 'int | None' = None, name:
    ↪ 'str' = 'pushforward measure') -> 'PushforwardMeasure'
```

Definition. Construct the pushforward of a finite base measure through an exact affine map or declared callable.

Contract (D, C, H, R, X). Measures expose finite dimension, mass, moments, exactness, and a structural certificate. Atomic measures require compatible finite points and nonnegative finite weights. Interval measures use finite ordered bounds and nonnegative constant density. Products preserve factor order. Exact affine pushforwards validate dimensions and Jacobian data, while arbitrary callable pushforwards retain explicit unchecked regularity and purity assumptions.

Guarantees (E, P, B, K). Integer and `Fraction` data remain exact. Floating data are checked for finiteness and produce numerical or conditional evidence. Atomic work is linear in atom count, product moments multiply factor results, and affine polynomial pullback can grow combinatorially in term count. Callable pushforwards are definitions with stated assumptions, not global regularity proofs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused evidence is `tests/test_block19_integration.py`. The independent verifier for core operators, algorithms, and integration exercises representative construction, invariant, failure, exactness, numerical-residual, and resource paths for this contract family. The source validator for core operators, algorithms, and integration checks the exact signature, implementation identity, alias routes, card counts, unique anchor, and preservation of the reference cards and formulas. See Chapters 47 through 49 and Chapter 68.

C.1E Root nonlinear calculus, packet-jet, and execution facades: 90 entries

This root section documents the top-level import routes for the nonlinear subsystem documented in Section C.5. These routes expose derivative providers, composition machinery, obstruction and lifting objects, packet jets, sparse execution plans, snapshots, resumable streams, profiling records, optional accelerator boundaries, and ordered rooted-tree expansions directly through `komorebi_math`. Each card retains the domain contract while making the root alias, defining implementation, signature, and stability boundary explicit.

Contract family	Cards
Derivatives and composition	15
Defects, lifting, grading, and transport	27
Packet jets and sparse tensors	7
Execution, snapshots, streaming, and profiling	35
Rooted-tree expansions and majorants	6
Total	**90**

The facade does not create a second implementation. Every callable or class card requires identity with its `komorebi_math.nonlinear` route and its reflected owner. Optional JAX, Torch, and CuPy symbols retain their unavailable-

backend contracts when the corresponding runtime is absent. The recorded CPU-safe validation does not constitute framework or accelerator qualification.

Derivatives and composition (15 cards).

C.1E · AutomaticDifferentiationProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AutomaticDifferentiationProvider`. Reflected implementation `komorebi_math.nonlinear.autodiff.AutomaticDifferentiationProvider`. The same runtime object is also available through `komorebi_math.nonlinear.AutomaticDifferentiationProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', jvp: 'DirectionalJVP', source_dimension: 'int', target_dimension: 'int',
   ↪ max_order: 'int' = 4, exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, name: 'str' = 'automatic
   ↪ differentiation provider') -> None
```

Definition. Framework-neutral higher derivatives obtained by nested JVP calls.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process. Principal public operations and properties are `supports_order`, `value`, `derivative`, `validation_certificate`, `to_dict`.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls. The provenance registry records `PSC-III-N04A` as Directional automatic-differentiation adapter. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 37.

C.1E · CallableDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CallableDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.CallableDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.CallableDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', derivatives: 'Mapping[int, DirectionalDerivative]', source_dimension: 'int',
   ↪ target_dimension: 'int', exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, name: 'str' =
   ↪ 'declared derivative provider') -> None
```

Definition. A map with explicitly supplied directional derivative callables.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the

optional symbolic dependency. Principal public operations and properties are `available_orders`, `supports_order`, `value`, `derivative`, `validation_certificate`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-D02` as Declared finite dimensional derivative provider. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 37 and 38.

C.1E · `ComposedDerivativeProvider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ComposedDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.composition.ComposedDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.ComposedDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(outer: 'DerivativeProvider', inner: 'DerivativeProvider', *, name: 'str | None' = None) -> 'None'
```

Definition. Expose a composition as another derivative provider.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records. Principal public operations and properties are `supports_order`, `value`, `derivative`.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded. The provenance registry records `PSC-III-D12` as Composed derivative provider. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `CuPyDeviceDerivativeProvider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CuPyDeviceDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.execution.CupyDeviceDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.CuPyDeviceDerivativeProvider`. The public export name maps to implementation object `CupyDeviceDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (`s`).

```
(*args, **kwargs)
```

Definition. Optional protocol consumed by `CupyPacketJetExecutor`.

Contract (`D, C, H, R, X`). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `supports_order`, `device_derivative`.

Guarantees (`E, P, B, K`). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `CuPyPacketJetExecutor`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.CuPyPacketJetExecutor`. Reflected implementation `komorebi_math.nonlinear.execution.CupyPacketJetExecutor`. The same runtime object is also available through `komorebi_math.nonlinear.CuPyPacketJetExecutor`. The public export name maps to implementation object `CupyPacketJetExecutor`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (`s`).

```
(family: 'PacketJetFamily', plan: 'PacketJetExecutionPlan | None' = None) -> 'None'
```

Definition. Device-resident packet projections and polynomial jet reconstruction.

Contract (`D, C, H, R, X`). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `execute`, `synchronize`, `hardware_certificate`.

Guarantees (`E, P, B, K`). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · CuPyPacketJetSnapshotExecutor

Identity (q, a, t, k). Public research-manifest route komorebi_math.CuPyPacketJetSnapshotExecutor. Reflected implementation komorebi_math.nonlinear.gpu.CuPySnapshotExecutor. The same runtime object is also available through komorebi_math.nonlinear.CuPyPacketJetSnapshotExecutor. The public export name maps to implementation object CuPySnapshotExecutor. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1E-EXECUTION.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', *, dtype: 'Any | None' = None) -> 'None'
```

Definition. Device evaluator for one sparse PacketJetSnapshot.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance. Principal public operations and properties are evaluate_batch, evaluate.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified. The provenance registry records PSC-III-N59 as Sparse CuPy packet-jet execution. Its recorded status is finite certificate. Recorded limitation: no performance claim without matched hardware benchmarking.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are tests/test_block16_gpu_qualification.py and tests/test_nonlinear_execution.py. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43. The recorded reference environment had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.1E · CuPyPolynomialDerivativeProvider

Identity (q, a, t, k). Public research-manifest route komorebi_math.CuPyPolynomialDerivativeProvider. Reflected implementation komorebi_math.nonlinear.execution.CupyPolynomialDerivativeProvider. The same runtime object is also available through komorebi_math.nonlinear.CuPyPolynomialDerivativeProvider. The public export name maps to implementation object CupyPolynomialDerivativeProvider. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1E-EXECUTION.

Manifest signature (s).

```
(tensors: 'Mapping[int, Any]', *, source_dimension: 'int | None' = None, target_dimension: 'int | None' = None,
    ↪ tolerance: 'float' = 1e-10, name: 'str' = 'CuPy polynomial derivative provider') -> 'None'
```

Definition. Dense polynomial derivatives resident on one CuPy device.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are degree, supports_order, device_value, value, device_derivative, derivative, synchronize.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `CuPyRuntimeStatus`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CuPyRuntimeStatus`. Reflected implementation `komorebi_math.nonlinear.gpu.CuPyRuntimeStatus`. The same runtime object is also available through `komorebi_math.nonlinear.CuPyRuntimeStatus`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(installed: 'bool', runtime_available: 'bool', device_count: 'int', runtime_version: 'int | None', error: 'str |
    ↪ None' = None) -> None
```

Definition. Observed CuPy import and CUDA device state.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43. The recorded reference environment had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.1E · `CuPySnapshotExecutor`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CuPySnapshotExecutor`. Reflected implementation `komorebi_math.nonlinear.gpu.CuPySnapshotExecutor`. The same runtime object is also available through `komorebi_math.nonlinear.CuPySnapshotExecutor`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', *, dtype: 'Any | None' = None) -> 'None'
```

Definition. Device evaluator for one sparse `PacketJetSnapshot`.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance. Principal public operations and properties are `evaluate_batch`, `evaluate`.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified. The provenance registry records `PSC-`

III-N59 as Sparse CuPy packet-jet execution. Its recorded status is finite certificate. Recorded limitation: no performance claim without matched hardware benchmarking.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are tests/test_block16_gpu_qualification.py and tests/test_nonlinear_execution.py. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43. The recorded reference environment had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

C.1E · CuPyValidationResult

Identity (q, a, t, k). Public research-manifest route komorebi_math.CuPyValidationResult. Reflected implementation komorebi_math.nonlinear.gpu.CuPyValidationResult. The same runtime object is also available through komorebi_math.nonlinear.CuPyValidationResult. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1E-EXECUTION.

Manifest signature (s).

```
(probe_count: 'int', maximum_residual: 'float', runtime: 'CuPyRuntimeStatus', certificate: 'Certificate') -> None
```

Definition. Matched CPU and CuPy packet-jet validation data.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are tests/test_block16_gpu_qualification.py and tests/test_nonlinear_execution.py. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43. The recorded reference environment had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

Derivatives and composition (15 cards).

C.1E · DirectionalJVP

Identity (q, a, t, k). Public research-manifest route komorebi_math.DirectionalJVP. Reflected implementation komorebi_math.nonlinear.autodiff.DirectionalJVP. The same runtime object is also available through komorebi_math.nonlinear.DirectionalJVP. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1E-DERIVATIVE.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. One forward-mode Jacobian-vector product primitive.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 37.

Defects, lifting, grading, and transport (27 cards).

C.1E · `FilteredCorrectionProblem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FilteredCorrectionProblem`. Reflected implementation `komorebi_math.nonlinear.filtered.FilteredCorrectionProblem`. The same runtime object is also available through `komorebi_math.nonlinear.FilteredCorrectionProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(source: 'FilteredVectorSpace', target: 'FilteredVectorSpace', correction_map: 'Any', defect: 'Any', depth: 'int')
    ↪  -> 'None'
```

Definition. One associated-graded correction problem over a prime field.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `induced_map`, `solve`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions. The provenance registry records `PSC-III-T51` as One-step filtered lifting criterion. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 42.

C.1E · `FilteredVectorSpace`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FilteredVectorSpace`. Reflected implementation `komorebi_math.nonlinear.filtered.FilteredVectorSpace`. The same runtime object is also available through `komorebi_math.nonlinear.FilteredVectorSpace`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(dimension: 'int', levels: 'Mapping[int, Any]', *, prime: 'int') -> 'None'
```

Definition. A finite decreasing filtration `F^0 V >= ... >= F^N V = 0`.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `from_weights`, `basis`, `dimension_at`, `contains`, `graded_basis`, `graded_dimension`, `graded_coordinates`, `lift_graded`, `certificate`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions. The provenance registry records `PSC-III-D50` as Finite decreasing filtration over a prime field. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 42.

C.1E · `FiniteAbelianGroup`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteAbelianGroup`. Reflected implementation `komorebi_math.nonlinear.graded.FiniteAbelianGroup`. The same runtime object is also available through `komorebi_math.nonlinear.FiniteAbelianGroup`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(labels: 'Sequence[str]', addition: 'Mapping[tuple[str, str], str]', *, zero: 'str', validate: 'bool' = True) ->
    ↪ 'None'
```

Definition. A finite abelian group represented by an explicit addition table.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes. Principal public operations and properties are `cyclic`, `add`, `sum`, `inverse`, `certificate`, `to_dict`.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred. The provenance registry records `PSC-III-D17` as Finite abelian grading group. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Derivatives and composition (15 cards).

C.1E · FiniteDifferenceDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteDifferenceDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.FiniteDifferenceDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.FiniteDifferenceDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(function: 'Callable[[np.ndarray], Any]', source_dimension: 'int', target_dimension: 'int', step: 'float' =
   ↪ 0.0001, max_order: 'int' = 4, name: 'str' = 'central finite difference provider', exactness: 'Exactness' =
   ↪ <Exactness.NUMERICAL: 'numerical'>) -> None
```

Definition. Numerical directional derivatives by recursive central differences.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `supports_order`, `value`, `derivative`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-N03` as Recursive central directional differences. Its recorded status is `finite certificate`. The provenance record notes that roundoff and truncation error grow with derivative order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 37 and 38.

Defects, lifting, grading, and transport (27 cards).

C.1E · FiniteFilteredCochainComplex

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteFilteredCochainComplex`. Reflected implementation `komorebi_math.nonlinear.filtered.FiniteFilteredCochainComplex`. The same runtime object is also available through `komorebi_math.nonlinear.FiniteFilteredCochainComplex`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(dimensions: 'Mapping[int, int]', differentials: 'Mapping[int, Any]', filtrations: 'Mapping[int,
   ↪ FilteredVectorSpace]', *, prime: 'int') -> 'None'
```

Definition. An exact filtered cochain complex over a prime field.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller. Principal public operations and properties are `differential`, `page`, `total_cohomology_dimensions`, `spectral_sequence`.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence.

It does not prove completeness or convergence beyond those assumptions. The provenance registry records `PSC-III-S54` as Spectral sequence of a finite filtered complex. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 42.

C.1E · FiniteLiftTree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteLiftTree`. Reflected implementation `komorebi_math.nonlinear.lifting.FiniteLiftTree`. The same runtime object is also available through `komorebi_math.nonlinear.FiniteLiftTree`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(prime: 'int', levels: 'tuple[tuple[LiftTreeNode, ...], ...]') -> None
```

Definition. A finite prefix of a prime power lift tree.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `max_depth`, `terminal_branches`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · GradedPacketOperation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.GradedPacketOperation`. Reflected implementation `komorebi_math.nonlinear.graded.GradedPacketOperation`. The same runtime object is also available through `komorebi_math.nonlinear.GradedPacketOperation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', packets: 'PacketSystem', arity: 'int', operation: 'GradedOperationCallable', *,
   ↪  exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance: 'float | None' = None, name: 'str' =
   ↪  'graded packet operation') -> 'None'
```

Definition. A multilinear operation tested against a finite packet grading.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes. Principal public operations and properties are `evaluate`, `grading_certificate`, `packet_convolution`.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite

Maurer Cartan series is inferred. The provenance registry records `PSC-III-T18` as Graded packet convolution. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

C.1E · `HilbertObstructionProjector`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.HilbertObstructionProjector`. Reflected implementation `komorebi_math.nonlinear.correction.HilbertObstructionProjector`. The same runtime object is also available through `komorebi_math.nonlinear.HilbertObstructionProjector`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(correction_map: 'Any', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Moore–Penrose correction and orthogonal cokernel projection.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point. Principal public operations and properties are `solve`.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions. The provenance registry records `PSC-III-T31` as Orthogonal Hilbert obstruction projector. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 41.

Derivatives and composition (15 cards).

C.1E · `JaxDerivativeProvider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.JaxDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.autodiff.JaxDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.JaxDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', max_order: 'int' = 4, dtype:
    ↪ 'str | None' = None, name: 'str' = 'JAX derivative provider', exactness: 'Exactness' = <Exactness.NUMERICAL:
    ↪ 'numerical'>) -> None
```

Definition. Nested `jax.jvp` derivatives with lazy framework import.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Frame-

work discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process. Principal public operations and properties are `available`, `value`, `derivative`, `to_dict`.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls. The provenance registry records `PSC-III-N04J` as Lazy JAX derivative adapter. Its recorded status is `finite certificate`. The provenance record notes that device and precision behavior are controlled by the external JAX runtime.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 37.

Defects, lifting, grading, and transport (27 cards).

C.1E · KatoTransport

Identity (q, a, t, k). Public research-manifest route `komorebi_math.KatoTransport`. Reflected implementation `komorebi_math.nonlinear.transport.KatoTransport`. The same runtime object is also available through `komorebi_math.nonlinear.KatoTransport`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(system: 'MovingPacketSystem') -> 'None'
```

Definition. Numerical finite Kato transport for a moving packet system.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance. Principal public operations and properties are `evolve`, `direct_rotation_product`, `refinement_certificate`.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates. The provenance registry records `PSC-III-T58` as Finite smooth packet transport. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_transport.py`, and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 40 and 44.

C.1E · LinearLiftProblem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LinearLiftProblem`. Reflected implementation `komorebi_math.nonlinear.lifting.LinearLiftProblem`. The same runtime object is also available through `komorebi_math.nonlinear.LinearLiftProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(matrix: 'Any', rhs: 'Any', point: 'Any', *, prime: 'int', depth: 'int') -> 'None'
```

Definition. Lift a linear congruence one prime power at a time.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `step`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit. The provenance registry records `PSC-III-T28` as One step lifting criterion. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · `LinearObstructionProblem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LinearObstructionProblem`. Reflected implementation `komorebi_math.nonlinear.obstruction.LinearObstructionProblem`. The same runtime object is also available through `komorebi_math.nonlinear.LinearObstructionProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(correction_map: 'Any', defect: 'Any', *, backend: 'str | LinearAlgebraBackend | None' = None, tolerance: 'float' =
    ↪ 1e-10) -> 'None'
```

Definition. Compute the obstruction to solving `D u = -defect`.

Contract (D, C, H, R, X). A linear obstruction problem requires a finite matrix and a target residual of matching dimension. The obstruction square additionally requires compatible maps whose two routes can be compared. Tolerances must be positive and finite when numerical rank decisions are used. Principal public operations and properties are `solve`.

Guarantees (E, P, B, K). The solver separates the residual into a least squares range component and a cokernel obstruction component. The correction is accepted only when the obstruction norm is within tolerance. Certificates record residuals and rank information for the supplied finite matrix. They do not establish exact vanishing outside the represented arithmetic and tolerance model. The provenance registry records `PSC-III-D13` as Linear correction datum and cokernel obstruction. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_obstruction.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · LyapunovSchmidtReduction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LyapunovSchmidtReduction`. Reflected implementation `komorebi_math.nonlinear.correction.LyapunovSchmidtReduction`. The same runtime object is also available through `komorebi_math.nonlinear.LyapunovSchmidtReduction`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', base_point: 'Any', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Numerical SVD realization of local Lyapunov–Schmidt reduction.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point. Principal public operations and properties are `solve_range`, `base_derivative_certificate`, `reduced_second_derivative`.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions. The provenance registry records `PSC-III-T33` as Finite local Lyapunov–Schmidt reduction. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 41.

C.1E · MovingPacketSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MovingPacketSystem`. Reflected implementation `komorebi_math.nonlinear.transport.MovingPacketSystem`. The same runtime object is also available through `komorebi_math.nonlinear.MovingPacketSystem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(projectors: 'Callable[[float], Iterable[Any]]', derivatives: 'Callable[[float], Iterable[Any]]', *, tolerance:
    ↪ 'float' = 1e-09, reference_time: 'float' = 0.0) -> 'None'
```

Definition. A differentiable finite family of complete orthogonal projectors.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance. Principal public operations and properties are `packets`, `packet_derivatives`, `derivative_certificate`, `canonical_generator`, `generator_certificate`.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates. The provenance registry records `PSC-III-D56` as Smooth finite packet system. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_transport.py`, and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family.

The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 40 and 44.

Rooted-tree expansions and majorants (6 cards).

C.1E · `MultilinearOperation`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.MultilinearOperation`. Reflected implementation `collections.abc.Callable`. The same runtime object is also available through `komorebi_math.nonlinear.MultilinearOperation`. The public export name maps to implementation object `Callable`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `data`. Profile `C1E-ROOTED-TREES`.

Manifest signature (`s`).

```
(*args, **kwargs)
```

Definition. Callable type alias for one finite multilinear operation on a tuple of values.

Contract (`D, C, H, R, X`). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (`E, P, B, K`). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Defects, lifting, grading, and transport (27 cards).

C.1E · `NonlinearPacketMap`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.NonlinearPacketMap`. Reflected implementation `komorebi_math.nonlinear.coordinates.NonlinearPacketMap`. The same runtime object is also available through `komorebi_math.nonlinear.NonlinearPacketMap`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (`s`).

```
(function: 'Callable[[Any], Any]', source: 'PacketSystem', target: 'PacketSystem', name: 'str' = 'nonlinear packet
   ↪ map') -> None
```

Definition. A nonlinear map evaluated through exact packet analysis and synthesis.

Contract (`D, C, H, R, X`). A nonlinear packet map requires a callable finite map and compatible finite source and target packet systems. Inputs must have the source ambient dimension. Packet evaluation projects the input into declared source channels, evaluates the map, and resolves the output through the target packet family. Principal public operations and properties are `apply`, `certificate`, `iterate`, `fixed_point_residual`.

Guarantees (`E, P, B, K`). For a complete target packet system, the recorded packet outputs reconstruct the direct finite map value within the certificate tolerance. The certificate concerns one supplied input and one implemented packet decomposition. It does not imply global linearity, smoothness, or invertibility. Work is dominated by packet projection and one map evaluation. The provenance registry records `PSC-III-D01` as Nonlinear packet coordinate map. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_coordinates_defects.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · NonlinearRefinementDefect

Identity (q, a, t, k). Public research-manifest route `komorebi_math.NonlinearRefinementDefect`. Reflected implementation `komorebi_math.nonlinear.defects.NonlinearRefinementDefect`. The same runtime object is also available through `komorebi_math.nonlinear.NonlinearRefinementDefect`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(fine_map: 'Callable[[Any], Any]', coarse_map: 'Callable[[Any], Any]', coarsen_source: 'Any', coarsen_target:
   ↪  'Any') -> None
```

Definition. Pointwise defect `C_Y F_f(x) - F_c(C_X x)`.

Contract (D, C, H, R, X). A nonlinear refinement defect requires fine and coarse maps together with finite source and target coarsening operators of compatible shape. Iterated bounds additionally require a nonnegative iteration count and a caller supplied coarse Lipschitz bound. Principal public operations and properties are `evaluate`, `norm`, `composition_identity`, `iterated_orbit_bound`, `fixed_point_bound`.

Guarantees (E, P, B, K). The direct defect is the finite discrepancy between coarsening after the fine map and applying the coarse map after source coarsening. Orbit estimates are conditional on the supplied Lipschitz constant and measured finite defects. They do not independently prove a global contraction property. The provenance registry records `PSC-III-D10` as Nonlinear refinement defect. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_coordinates_defects.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · NonlinearSchurElimination

Identity (q, a, t, k). Public research-manifest route `komorebi_math.NonlinearSchurElimination`. Reflected implementation `komorebi_math.nonlinear.elimination.NonlinearSchurElimination`. The same runtime object is also available through `komorebi_math.nonlinear.NonlinearSchurElimination`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(retained_provider: 'DerivativeProvider', hidden_provider: 'DerivativeProvider', retained_dimension: 'int',
   ↪  hidden_dimension: 'int', base_retained: 'Any', base_hidden: 'Any', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. First and second derivatives after eliminating hidden variables.

Contract (D, C, H, R, X). Nonlinear Schur elimination requires retained and hidden derivative providers with a declared split of visible and hidden coordinates. The hidden derivative at the base point must be square and numerically invertible. Hidden solves require an initial point, a finite iteration limit, and a positive tolerance. Principal public operations and properties are `first_derivatives`, `second_derivative`, `solve_hidden`, `reduced_value`.

Guarantees (E, P, B, K). The first derivative contract implements the finite implicit derivative and reduced Schur derivative. The second derivative contract applies the declared provider derivatives through order two. Exact symbolic inputs may retain exact matrices. Numerical inputs receive residual certificates tied to the selected solve and

base point. These are local finite statements, not global existence claims. The provenance registry records `PSC-III-T41` as Finite nonlinear Schur elimination. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 41.

Rooted-tree expansions and majorants (6 cards).

C.1E · `OrderedRootedTree`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.OrderedRootedTree`. Reflected implementation `komorebi_math.nonlinear.trees.OrderedRootedTree`. The same runtime object is also available through `komorebi_math.nonlinear.OrderedRootedTree`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-ROOTED-TREES`.

Manifest signature (s).

```
(children: "tuple['OrderedRootedTree', ...]" = ()) -> None
```

Definition. An unlabeled ordered rooted tree.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius. Principal public operations and properties are `leaf`, `is_leaf`, `arity`, `height`, `leaf_count`, `internal_count`, `vertex_count`, `arity_profile`, `prefix`, `to_dict`.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records `PSC-III-D13` as Finite ordered rooted tree. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Packet jets and sparse tensors (7 cards).

C.1E · `PacketJet`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJet`. Reflected implementation `komorebi_math.nonlinear.jets.PacketJet`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJet`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', point: 'Any', source: 'PacketSystem', target: 'PacketSystem', output_index:
    ↪ 'int', input_indices: 'tuple[int, ...]') -> None
```

Definition. One projected multilinear derivative block.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive

finite tolerances and explicit evaluation budgets. Principal public operations and properties are `order`, `address`, `exactness`, `evaluate`, `norm_bound`, `symmetry_certificate`, `to_dict`.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-D06` as Finite packet jet. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `PacketJetBatchResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetBatchResult`. Reflected implementation `komorebi_math.nonlinear.execution.PacketJetBatchResult`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetBatchResult`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(evaluations: 'tuple[PacketJetEvaluation, ...]', reconstructed: 'Any', direct: 'Any', derivative_calls: 'int',
    ↪ input_projections: 'int', output_projections: 'int', pruned_blocks: 'int', backend: 'str', returned_to_host:
    ↪ 'bool', certificate: 'Certificate') -> None
```

Definition. Result of one projection-cached packet-jet execution.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `as_mapping`, `value`, `to_dict`.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `PacketJetComplexityEstimate`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetComplexityEstimate`. Reflected implementation `komorebi_math.nonlinear.profiling.PacketJetComplexityEstimate`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetComplexityEstimate`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(order: 'int', source_dimension: 'int', target_dimension: 'int', source_packets: 'int', target_packets: 'int',
   ↪ family_addresses: 'int', active_addresses: 'int', pruned_addresses: 'int', input_groups: 'int',
   ↪ naive_derivative_calls: 'int', planned_derivative_calls: 'int', projected_input_vectors: 'int',
   ↪ output_projections: 'int', dense_basis_evaluations: 'int', dense_tensor_elements: 'int', certificate:
   ↪ 'Certificate') -> None
```

Definition. Exact finite counts implied by packet and ambient dimensions.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets. Principal public operations and properties are `derivative_call_reduction`, `to_dict`.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `PacketJetExecutionPlan`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetExecutionPlan`. Reflected implementation `komorebi_math.nonlinear.execution.PacketJetExecutionPlan`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetExecutionPlan`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(order: 'int', source_names: 'tuple[str, ...]', target_names: 'tuple[str, ...]', groups:
   ↪ 'tuple[PacketJetInputGroup, ...]', active_addresses: 'tuple[PacketJetAddress, ...]', pruned_addresses:
   ↪ 'tuple[PacketJetAddress, ...]', support_was_supplied: 'bool', support_complete: 'bool', certificate:
   ↪ 'Certificate') -> None
```

Definition. A deterministic grouping of packet-jet blocks by projected inputs.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device. Principal public operations and properties are `active_address_count`, `pruned_address_count`, `full_address_count`, `derivative_call_count`, `naive_derivative_call_count`, `derivative_call_reduction`, `matches`, `to_dict`.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly. The provenance registry records `PSC-III-A10` as Projection-cached packet-jet execution plan. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implemen-

tation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Packet jets and sparse tensors (7 cards).

C.1E · PacketJetFamily

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetFamily`. Reflected implementation `komorebi_math.nonlinear.jets.PacketJetFamily`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetFamily`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', point: 'Any', source: 'PacketSystem', target: 'PacketSystem', order: 'int') ->
    ↪ 'None'
```

Definition. Every packet block of one derivative order at one base point.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets. Principal public operations and properties are `jet`, `addresses`, `reconstruct`, `reconstruction_certificate`, `to_dict`.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-T07` as Exact reconstruction of finite packet derivatives. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · PacketJetProfileReport

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetProfileReport`. Reflected implementation `komorebi_math.nonlinear.profiling.PacketJetProfileReport`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetProfileReport`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(estimate: 'PacketJetComplexityEstimate', stages: 'tuple[RuntimeStageProfile, ...]', environment: 'Mapping[str,
    ↪ Any]', certificate: 'Certificate') -> None
```

Definition. Exact counts paired with environment-specific runtime observations.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets. Principal public operations and properties are `to_dict`.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observa-

tions. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `PacketJetSnapshot`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetSnapshot`. Reflected implementation `komorebi_math.nonlinear.snapshots.PacketJetSnapshot`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetSnapshot`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(address: 'PacketJetAddress', source_dimension: 'int', target_dimension: 'int', provider_name: 'str', exactness:
    ↪ 'Exactness', point: 'tuple[Any, ...]', coefficients: 'tuple[PacketJetCoefficient, ...]',
    ↪ capture_certificate: 'Certificate') -> None
```

Definition. A provider-independent sparse coefficient record of one packet jet.

Contract (D, C, H, R, X). A snapshot captures one fixed packet jet by evaluating the ambient standard-basis tuples through an explicit finite budget. The source and target dimensions, base point, address, provider name, exactness, and sparse coefficients are stored in the record. Snapshot evaluation requires direction vectors of the recorded source dimension. Principal public operations and properties are `order`, `nnz`, `dense_coefficient_count`, `coefficient`, `evaluate`, `to_dense`, `comparison_certificate`, `to_dict`.

Guarantees (E, P, B, K). The snapshot is provider-independent after capture and reconstructs the recorded multilinear block from its stored coefficients. Its comparison certificate checks matched evaluations against the source jet on supplied probes. Exact coefficients preserve exact arithmetic. Numerical coefficients use the stored tolerance and certificate. Dense capture cost grows as the source dimension raised to the jet order. The provenance registry records `PSC-III-D58` as Finite packet-jet snapshot. Its recorded status is `finite certificate`. Recorded limitation: snapshot represents one fixed order, address, and base point.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 38 and 43.

C.1E · `PacketJetSnapshotStreamReader`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetSnapshotStreamReader`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetSnapshotStreamReader`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetSnapshotStreamReader`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(path: 'str | os.PathLike[str]', *, allow_incomplete: 'bool' = False, verify_chunks: 'bool' = False) -> 'None'
```

Definition. Bounded-memory reader for a complete or explicitly allowed partial stream.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed. Principal public operations and properties are `complete`, `iter_chunks`, `iter_coefficients`, `select`, `evaluate`, `load_snapshot`, `verify`.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `PacketJetStreamChunkRecord`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetStreamChunkRecord`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamChunkRecord`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetStreamChunkRecord`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(index: 'int', filename: 'str', basis_start: 'int', basis_stop: 'int', coefficient_start: 'int', coefficient_stop:
    ↪  'int', payload_sha256: 'str', byte_count: 'int') -> None
```

Definition. One immutable chunk index entry in a packet-jet stream manifest.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed. Principal public operations and properties are `coefficient_count`, `basis_count`, `to_dict`, `from_dict`.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · PacketJetStreamManifest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetStreamManifest`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamManifest`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetStreamManifest`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(state: 'StreamState', producer_version: 'str', address: 'PacketJetAddress', source_dimension: 'int',
   ↪ target_dimension: 'int', provider_name: 'str', exactness: 'Exactness', point: 'tuple[Any, ...]', tolerance:
   ↪ 'float', dense_coefficient_count: 'int', capture_mode: 'CaptureMode', source_digest: 'str', metadata_sha256:
   ↪ 'str', chunk_size: 'int', evaluations_completed: 'int', coefficients_completed: 'int',
   ↪ maximum_omitted_basis_norm: 'float', chunks: 'tuple[PacketJetStreamChunkRecord, ...]', capture_certificate:
   ↪ 'Certificate | None', stream_sha256: 'str') -> None
```

Definition. Validated metadata and progress for one chunked packet-jet stream.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed. Principal public operations and properties are `complete`, `order`, `metadata_dict`, `to_payload`, `from_payload`.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · PacketJetStreamSelection

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetStreamSelection`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamSelection`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetStreamSelection`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(coefficient_start: 'int', coefficient_stop: 'int', coefficients: 'tuple[PacketJetCoefficient, ...]',
   ↪ complete_snapshot: 'bool', certificate: 'Certificate') -> None
```

Definition. A bounded coefficient selection loaded from a packet-jet stream.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `PacketJetStreamWriteResult`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketJetStreamWriteResult`. Reflected implementation `komorebi_math.nonlinear.streaming.PacketJetStreamWriteResult`. The same runtime object is also available through `komorebi_math.nonlinear.PacketJetStreamWriteResult`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(destination: 'Path', active_path: 'Path', completed: 'bool', resumed: 'bool', chunks_written: 'int',
    ↪ evaluations_written: 'int', coefficients_written: 'int', manifest: 'PacketJetStreamManifest', certificate:
    ↪ 'Certificate') -> None
```

Definition. Progress returned by a direct or snapshot stream write.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Derivatives and composition (15 cards).

C.1E · `PolynomialDerivativeProvider`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolynomialDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.PolynomialDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.PolynomialDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(tensors: 'Mapping[int, Any]', *, source_dimension: 'int | None' = None, target_dimension: 'int | None' = None,
    ↪ exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance: 'float' = 1e-10, name: 'str' =
    ↪ 'polynomial derivative provider') -> 'None'
```

Definition. A finite polynomial map represented by symmetric coefficient tensors.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction

vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `degree`, `supports_order`, `value`, `derivative`, `symmetry_certificate`.

Guarantees (`E`, `P`, `B`, `K`). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-D04` as Symmetric polynomial derivative tensors. Its recorded status is `definition`.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 37 and 38.

Rooted-tree expansions and majorants (6 cards).

C.1E · `PolynomialFixedPointProblem`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.PolynomialFixedPointProblem`. Reflected implementation `komorebi_math.nonlinear.trees.PolynomialFixedPointProblem`. The same runtime object is also available through `komorebi_math.nonlinear.PolynomialFixedPointProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-ROOTED-TREES`.

Manifest signature (`s`).

```
(seed: 'Any', operations: 'Mapping[int, MultilinearOperation]', *, exactness: 'Exactness' = <Exactness.NUMERICAL:
    ↪ 'numerical'>, tolerance: 'float' = 1e-10, name: 'str' = 'polynomial fixed-point problem') -> 'None'
```

Definition. A finite-dimensional equation `u = s + sum_r B_r(u,...,u)`.

Contract (`D`, `C`, `H`, `R`, `X`). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius. Principal public operations and properties are `operation`, `map`, `residual`, `picard`, `tree_value`, `tree_expansion`, `convergence_certificate`.

Guarantees (`E`, `P`, `B`, `K`). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records `PSC-III-T14A` as Finite polynomial rooted-tree expansion. Its recorded status is `finite certificate`.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Defects, lifting, grading, and transport (27 cards).

C.1E · PolynomialLiftProblem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolynomialLiftProblem`. Reflected implementation `komorebi_math.nonlinear.lifting.PolynomialLiftProblem`. The same runtime object is also available through `komorebi_math.nonlinear.PolynomialLiftProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(function: 'Callable[[tuple[int, ...]], Iterable[int]]', jacobian: 'Callable[[tuple[int, ...]], Any]', point:
   ↪ 'Any', *, prime: 'int', depth: 'int') -> 'None'
```

Definition. Lift a polynomial system by its Jacobian over the residual field.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget. Principal public operations and properties are `step`.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · RightInverseCorrectionProblem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RightInverseCorrectionProblem`. Reflected implementation `komorebi_math.nonlinear.correction.RightInverseCorrectionProblem`. The same runtime object is also available through `komorebi_math.nonlinear.RightInverseCorrectionProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(linear_map: 'Any', right_inverse: 'Any', nonlinear: 'Callable[[np.ndarray], Any]', target: 'Any', *, radius:
   ↪ 'float', lipschitz_bound: 'float', tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Solve `D x + N(x) = y` by the theorem's fixed-point map.

Contract (D, C, H, R, X). Correction contracts operate on finite matrices or derivative providers with explicit dimensions, tolerances, radii, right inverses, and Lipschitz bounds. Hilbert obstruction projection uses the declared linearized operator. Right inverse correction checks the supplied contraction inequalities. Lyapunov Schmidt reduction computes numerical kernel, complement, range, and obstruction coordinates at a specified base point. Principal public operations and properties are `hypothesis_certificate`, `solve`, `target_stability_bound`.

Guarantees (E, P, B, K). Certificates report finite residuals, rank decisions, obstruction norms, and the inequalities actually checked. A vanishing obstruction is always relative to the stored tolerance. Local contraction or Lyapunov Schmidt conclusions remain conditional on the supplied finite hypotheses. Matrix factorizations dominate cost and use storage quadratic in the ambient dimensions. The provenance registry records `PSC-III-T32` as Right-inverse nonlinear correction. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_correction_elimination.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 41.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · RuntimeProfileSample

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RuntimeProfileSample`. Reflected implementation `komorebi_math.nonlinear.profiling.RuntimeProfileSample`. The same runtime object is also available through `komorebi_math.nonlinear.RuntimeProfileSample`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(duration_ns: 'int', traced_peak_bytes: 'int') -> None
```

Definition. One observed duration and Python allocation peak.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · RuntimeStageProfile

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RuntimeStageProfile`. Reflected implementation `komorebi_math.nonlinear.profiling.RuntimeStageProfile`. The same runtime object is also available through `komorebi_math.nonlinear.RuntimeStageProfile`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(name: 'str', scope: 'str', warmup: 'int', samples: 'tuple[RuntimeProfileSample, ...]') -> None
```

Definition. Repeated observations for one precisely named runtime stage.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets. Principal public operations and properties are `repetitions`, `minimum_duration_ns`, `median_duration_ns`, `maximum_duration_ns`, `median_peak_bytes`, `maximum_peak_bytes`, `to_dict`.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Packet jets and sparse tensors (7 cards).

C.1E · SparsePolynomialDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SparsePolynomialDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.sparse.SparsePolynomialDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.SparsePolynomialDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(tensors: 'Mapping[int, SparseSymmetricTensor | Mapping[tuple[int, ...], Any] | Any]', *, source_dimension: 'int |
   ↪ None' = None, target_dimension: 'int | None' = None, exactness: 'Exactness' = <Exactness.NUMERICAL:
   ↪ 'numerical'>, tolerance: 'float' = 1e-10, name: 'str' = 'sparse polynomial derivative provider') -> 'None'
```

Definition. Polynomial derivatives evaluated from sparse symmetric tensor orbits.

Contract (D, C, H, R, X). Sparse tensor records require nonnegative output indices, canonical nondecreasing source-index tuples, positive finite dimensions, and coefficients compatible with the selected exactness model. A sparse polynomial provider requires one finite tensor per declared derivative order and common source and target dimensions. Principal public operations and properties are `from_dense_provider`, `degree`, `stored_entry_count`, `dense_entry_count`, `storage_ratio`, `supports_order`, `value`, `derivative`, `to_dense_provider`, `storage_certificate`, `to_dict`.

Guarantees (E, P, B, K). Orbit storage represents symmetric ordered tensor entries without storing every permutation. Contraction and dense reconstruction agree with the implemented orbit expansion. Exact object arithmetic remains exact when requested and supported. Numerical compression uses the declared tolerance. Storage savings depend on symmetry and sparsity, while dense materialization still requires the full ambient tensor size. The provenance registry records `PSC-III-D04P` as Sparse polynomial derivative provider. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

C.1E · SparseSymmetricTensor

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SparseSymmetricTensor`. Reflected implementation `komorebi_math.nonlinear.sparse.SparseSymmetricTensor`. The same runtime object is also available through `komorebi_math.nonlinear.SparseSymmetricTensor`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(order: 'int', source_dimension: 'int', target_dimension: 'int', entries: 'tuple[SparseTensorEntry, ...]' = ()) ->
   ↪ None
```

Definition. One finite symmetric tensor stored by source-index orbits.

Contract (D, C, H, R, X). Sparse tensor records require nonnegative output indices, canonical nondecreasing source-index tuples, positive finite dimensions, and coefficients compatible with the selected exactness model. A sparse polynomial provider requires one finite tensor per declared derivative order and common source and target dimensions. Principal public operations and properties are `from_mapping`, `from_dense`, `stored_entry_count`, `dense_entry_count`, `expanded_nonzero_count`, `storage_ratio`, `contract`, `to_dense`, `certificate`, `to_dict`.

Guarantees (E, P, B, K). Orbit storage represents symmetric ordered tensor entries without storing every permutation. Contraction and dense reconstruction agree with the implemented orbit expansion. Exact object arithmetic remains exact when requested and supported. Numerical compression uses the declared tolerance. Storage savings depend on symmetry and sparsity, while dense materialization still requires the full ambient tensor size. The provenance registry records `PSC-III-D04S` as Sparse symmetric derivative tensor. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades

checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

C.1E · SparseTensorEntry

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SparseTensorEntry`. Reflected implementation `komorebi_math.nonlinear.sparse.SparseTensorEntry`. The same runtime object is also available through `komorebi_math.nonlinear.SparseTensorEntry`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(output: 'int', inputs: 'tuple[int, ...]', value: 'Any') -> None
```

Definition. One coefficient of a symmetric tensor orbit.

Contract (D, C, H, R, X). Sparse tensor records require nonnegative output indices, canonical nondecreasing source-index tuples, positive finite dimensions, and coefficients compatible with the selected exactness model. A sparse polynomial provider requires one finite tensor per declared derivative order and common source and target dimensions.

Guarantees (E, P, B, K). Orbit storage represents symmetric ordered tensor entries without storing every permutation. Contraction and dense reconstruction agree with the implemented orbit expansion. Exact object arithmetic remains exact when requested and supported. Numerical compression uses the declared tolerance. Storage savings depend on symmetry and sparsity, while dense materialization still requires the full ambient tensor size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · StreamedPacketJetEvaluation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.StreamedPacketJetEvaluation`. Reflected implementation `komorebi_math.nonlinear.streaming.StreamedPacketJetEvaluation`. The same runtime object is also available through `komorebi_math.nonlinear.StreamedPacketJetEvaluation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(value: 'np.ndarray', coefficient_start: 'int', coefficient_stop: 'int', total_coefficients: 'int',
    ↪ complete_snapshot: 'bool', certificate: 'Certificate') -> None
```

Definition. One chunk-wise packet-jet evaluation with an explicit coverage record.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Derivatives and composition (15 cards).

C.1E · SympyDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SympyDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.derivatives.SympyDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.SympyDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(expressions: 'Sequence[Any]', variables: 'Sequence[Any]', *, name: 'str' = 'SymPy derivative provider') -> 'None'
```

Definition. Exact directional derivatives of a finite SymPy expression vector.

Contract (D, C, H, R, X). Derivative providers expose one common finite dimensional interface for map evaluation and directional derivatives. A call must use an order supported by the provider and exactly that many direction vectors of the declared source dimension. Callable and polynomial providers trust explicitly supplied derivative data. The finite difference provider additionally requires a positive finite step. The SymPy provider requires the optional symbolic dependency. Principal public operations and properties are `supports_order`, `value`, `derivative`.

Guarantees (E, P, B, K). Polynomial and symbolic providers preserve exact objects where their inputs permit exact arithmetic. Callable providers inherit the exactness declared by the caller. Finite differences return numerical evidence only. Every provider checks dimensions and finite values before evaluation. Tensor contraction cost grows with derivative order and ambient dimension. The provenance registry records `PSC-III-E05` as Exact symbolic directional derivatives. Its recorded status is `finite certificate`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_sparse_autodiff.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 37 and 38.

C.1E · TorchDerivativeProvider

Identity (q, a, t, k). Public research-manifest route `komorebi_math.TorchDerivativeProvider`. Reflected implementation `komorebi_math.nonlinear.autodiff.TorchDerivativeProvider`. The same runtime object is also available through `komorebi_math.nonlinear.TorchDerivativeProvider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', max_order: 'int' = 4, dtype:
    ↪ 'str' = 'float64', device: 'str | None' = None, name: 'str' = 'PyTorch derivative provider', exactness:
    ↪ 'Exactness' = <Exactness.NUMERICAL: 'numerical'>) -> None
```

Definition. Nested `torch.func.jvp` derivatives with lazy framework import.

Contract (D, C, H, R, X). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process. Principal public operations and properties are `available`, `value`, `derivative`, `to_dict`.

Guarantees (E, P, B, K). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls. The provenance registry records `PSC-III-N04T` as Lazy PyTorch derivative adapter. Its recorded status is `finite certificate`. The provenance record notes that device and precision behavior are controlled by the external PyTorch runtime.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 37.

Defects, lifting, grading, and transport (27 cards).

C.1E · `TransportEdge`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.TransportEdge`. Reflected implementation `komorebi_math.nonlinear.holonomy.TransportEdge`. The same runtime object is also available through `komorebi_math.nonlinear.TransportEdge`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Any', name: 'str' = '') -> None
```

Definition. An invertible transport from `source` to `target`.

Contract (D, C, H, R, X). A transport graph requires a finite vertex set and directed edges carrying compatible square matrices. Path transport requires composable endpoints. Gluing and intertwining checks require a chosen root and finite tolerance. Fundamental holonomy is computed from the selected spanning structure and recorded non tree edges. Principal public operations and properties are `reversed_name`.

Guarantees (E, P, B, K). The graph routines compute exact path products for exact input matrices or numerical products otherwise. Certificates compare finite cycle transports, root gauges, and intertwining residuals. The result describes the supplied finite graph. It is not a continuum connection or topological classification without additional hypotheses.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_holonomy.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

C.1E · `TransportGraph`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.TransportGraph`. Reflected implementation `komorebi_math.nonlinear.holonomy.TransportGraph`. The same runtime object is also available through `komorebi_math.nonlinear.TransportGraph`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(vertices: 'Iterable[str]', edges: 'Iterable[TransportEdge]', *, backend: 'str | LinearAlgebraBackend | None' =
    ↪ None, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. A connected finite graph with invertible matrix transports.

Contract (D, C, H, R, X). A transport graph requires a finite vertex set and directed edges carrying compatible square matrices. Path transport requires composable endpoints. Gluing and intertwining checks require a chosen root and

finite tolerance. Fundamental holonomy is computed from the selected spanning structure and recorded non tree edges. Principal public operations and properties are `edge_label`, `oriented_matrix`, `spanning_tree`, `tree_transports`, `tree_gauge`, `gauge_transform`, `fundamental_holonomies`, `gluing_certificate`, `intertwine`.

Guarantees (`E`, `P`, `B`, `K`). The graph routines compute exact path products for exact input matrices or numerical products otherwise. Certificates compare finite cycle transports, root gauges, and intertwining residuals. The result describes the supplied finite graph. It is not a continuum connection or topological classification without additional hypotheses. The provenance registry records `PSC-III-D38` as Finite matrix transport system. Its recorded status is `definition`.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_holonomy.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

Derivatives and composition (15 cards).

C.1E · `autodiff_provider`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.autodiff_provider`. Reflected implementation `komorebi_math.nonlinear.autodiff.autodiff_provider`. The same runtime object is also available through `komorebi_math.nonlinear.autodiff_provider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-DERIVATIVE`.

Manifest signature (`s`).

```
(framework: 'str', function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', *,
   ↪  max_order: 'int' = 4, **options: 'Any') -> 'JaxDerivativeProvider | TorchDerivativeProvider'
```

Definition. Construct one supported external automatic-differentiation adapter.

Contract (`D`, `C`, `H`, `R`, `X`). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (`E`, `P`, `B`, `K`). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 37.

C.1E · `automatic_derivative_provider`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.automatic_derivative_provider`. Reflected implementation `komorebi_math.nonlinear.autodiff.autodiff_provider`. The same runtime object is also available through `komorebi_math.nonlinear.automatic_derivative_provider`. The public export name maps to implementation object `autodiff_provider`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-DERIVATIVE`.

Manifest signature (`s`).

```
(framework: 'str', function: 'Callable[[Any], Any]', source_dimension: 'int', target_dimension: 'int', *,
    ↪ max_order: 'int' = 4, **options: 'Any') -> 'JaxDerivativeProvider | TorchDerivativeProvider'
```

Definition. Construct one supported external automatic-differentiation adapter.

Contract (`D, C, H, R, X`). Automatic differentiation adapters require a callable finite dimensional map, positive source and target dimensions, a declared maximum order, and a directional Jacobian vector product primitive supplied either directly or by an optional framework. Direction counts must equal the requested derivative order. Framework discovery is isolated in child processes so that a broken optional runtime cannot terminate the calling process.

Guarantees (`E, P, B, K`). A successful provider returns the finite directional derivative computed by the selected JVP recursion and records numerical exactness unless the caller supplies a stronger justified classification. Framework availability means that an isolated probe imported the runtime and found the required JVP capability. It does not assert numerical agreement for every model or device. Work grows with derivative order and the number of nested JVP calls.

Work grows with derivative order and the number of nested JVP calls.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_sparse_autodiff.py`, `tests/test_block10_sparse_autodiff.py`, and `tests/test_optional_backend_probe.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 37.

Defects, lifting, grading, and transport (27 cards).

C.1E · build_lift_tree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.build_lift_tree`. Reflected implementation `komorebi_math.nonlinear.lifting.build_lift_tree`. The same runtime object is also available through `komorebi_math.nonlinear.build_lift_tree`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(problem_factory: 'Callable[[tuple[int, ...], int], LinearLiftProblem | PolynomialLiftProblem]', roots:
    ↪ 'Iterable[tuple[int, ...]]', *, prime: 'int', start_depth: 'int', max_depth: 'int', max_nodes: 'int' =
    ↪ 100000) -> 'FiniteLiftTree'
```

Definition. Build a finite lift tree from exact one step correction problems.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit. The provenance registry records `PSC-III-T30` as Finite lift tree construction. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe

execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · capture_packet_jet_stream

Identity (q, a, t, k). Public research-manifest route `komorebi_math.capture_packet_jet_stream`. Reflected implementation `komorebi_math.nonlinear.streaming.capture_packet_jet_stream`. The same runtime object is also available through `komorebi_math.nonlinear.capture_packet_jet_stream`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(jet: 'PacketJet', path: 'str | os.PathLike[str]', *, tolerance: 'float | None' = None, max_evaluations: 'int' =
    ↪ 10000000, chunk_size: 'int' = 1024, evaluation_budget: 'int | None' = None, resume: 'bool' = False,
    ↪ overwrite: 'bool' = False) -> 'PacketJetStreamWriteResult'
```

Definition. Capture a packet jet directly into bounded, resumable basis chunks.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes. The provenance registry records `PSC-III-D60` as Chunked resumable packet-jet capture. Its recorded status is `finite certificate`. Recorded limitations state that integrity digests are not signatures and that resuming assumes the provider behavior still agrees with its recorded identity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · compile_packet_jet_plan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compile_packet_jet_plan`. Reflected implementation `komorebi_math.nonlinear.execution.compile_packet_jet_plan`. The same runtime object is also available through `komorebi_math.nonlinear.compile_packet_jet_plan`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', support: 'PacketJetSupport | None' = None, *, max_addresses: 'int' = 1000000) ->
    ↪ 'PacketJetExecutionPlan'
```

Definition. Compile a projection-cached plan, pruning only certified zero blocks.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented

derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Defects, lifting, grading, and transport (27 cards).

C.1E · `conditional_projective_limit_completion`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.conditional_projective_limit_completion`. Reflected implementation `komorebi_math.nonlinear.filtered.conditional_projective_limit_completion`. The same runtime object is also available through `komorebi_math.nonlinear.conditional_projective_limit_completion`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(verified_prefix_depth: 'int', *, separated: 'bool', complete: 'bool', continuous: 'bool',
    ↪ compatible_infinite_branch: 'bool') -> 'ConditionalResult[ProjectiveLimitRecord]'
```

Definition. Record the conditional infinite filtered-lifting conclusion.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 42.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `cupy_runtime_status`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.cupy_runtime_status`. Reflected implementation `komorebi_math.nonlinear.gpu.cupy_runtime_status`. The same runtime object is also available through `komorebi_math.nonlinear.cupy_runtime_status`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
() -> 'CuPyRuntimeStatus'
```

Definition. Inspect CuPy and CUDA availability without raising on absent hardware.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and

compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43. The recorded reference environment had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

Defects, lifting, grading, and transport (27 cards).

C.1E · `direct_packet_rotation`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.direct_packet_rotation`. Reflected implementation `komorebi_math.nonlinear.transport.direct_packet_rotation`. The same runtime object is also available through `komorebi_math.nonlinear.direct_packet_rotation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(source: 'Iterable[Any]', target: 'Iterable[Any]', *, tolerance: 'float' = 1e-10) -> 'DirectRotationResult'
```

Definition. Return the polar unitary of `sum target[a] source[a]`.

Contract (D, C, H, R, X). Smooth transport requires complete finite orthogonal packet families of fixed dimension together with declared packet derivatives. Direct rotation requires two compatible packet families whose overlap sum is numerically invertible. Kato transport requires finite start and end times, a positive step count, and a positive tolerance.

Guarantees (E, P, B, K). Direct polar rotation returns a finite unitary intertwiner when its residual checks pass. Kato transport integrates the canonical finite generator with midpoint exponential steps and records unitarity, packet transport, and mesh refinement residuals. These certificates are numerical and path specific. They do not prove differentiability of an undeclared family or continuum convergence without external estimates. The provenance registry records `PSC-III-T55` as Direct rotation of finite packet systems. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_transport.py`, and `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 40 and 44.

C.1E · `divided_square_packets`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.divided_square_packets`. Reflected implementation `komorebi_math.nonlinear.graded.divided_square_packets`. The same runtime object is also available through `komorebi_math.nonlinear.divided_square_packets`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', components: 'Mapping[str, Any]', differential: 'LinearOperation', bracket:
    ↪ 'BracketOperation', divided_square: 'LinearOperation', *, exactness: 'Exactness' = <Exactness.NUMERICAL:
    ↪ 'numerical'>, tolerance: 'float' = 1e-10) -> 'DividedSquareResult'
```

Definition. Assemble `d eta + q(eta)` from divided-square packet identities.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `estimate_packet_jet_complexity`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.estimate_packet_jet_complexity`. Reflected implementation `komorebi_math.nonlinear.profiling.estimate_packet_jet_complexity`. The same runtime object is also available through `komorebi_math.nonlinear.estimate_packet_jet_complexity`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', support: 'PacketJetSupport | None' = None, *, plan: 'PacketJetExecutionPlan | None' =
    ↪ None, max_addresses: 'int' = 1000000) -> 'PacketJetComplexityEstimate'
```

Definition. Return exact finite operation counts for a packet-jet family.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · execute_packet_jet_plan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.execute_packet_jet_plan`. Reflected implementation `komorebi_math.nonlinear.execution.execute_packet_jet_plan`. The same runtime object is also available through `komorebi_math.nonlinear.execute_packet_jet_plan`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(plan: 'PacketJetExecutionPlan', family: 'PacketJetFamily', directions: 'Sequence[Any]', *, tolerance: 'float |
    ↪ None' = None) -> 'PacketJetBatchResult'
```

Definition. Execute a packet-jet plan with cached input projections.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · execute_packet_jets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.execute_packet_jets`. Reflected implementation `komorebi_math.nonlinear.execution.execute_packet_jets`. The same runtime object is also available through `komorebi_math.nonlinear.execute_packet_jets`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', directions: 'Sequence[Any]', *, support: 'PacketJetSupport | None' = None, tolerance:
    ↪ 'float | None' = None, max_addresses: 'int' = 1000000) -> 'PacketJetBatchResult'
```

Definition. Compile and execute one projection-cached packet-jet family.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator

for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Derivatives and composition (15 cards).

C.1E · faa_di_bruno

Identity (q, a, t, k). Public research-manifest route `komorebi_math.faa_di_bruno`. Reflected implementation `komorebi_math.nonlinear.composition.faa_di_bruno`. The same runtime object is also available through `komorebi_math.nonlinear.faa_di_bruno`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(outer: 'DerivativeProvider', inner: 'DerivativeProvider', point: 'Any', directions: 'Sequence[Any]', *,
    ↪ direct_provider: 'DerivativeProvider | None' = None, tolerance: 'float' = 1e-09, retain_terms: 'bool' =
    ↪ True) -> 'FaaDiBrunoResult'
```

Definition. Evaluate the directional higher chain rule for `outer(inner(x))`.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded. The provenance registry records `PSC-III-T10` as Finite dimensional Faà di Bruno formula. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Defects, lifting, grading, and transport (27 cards).

C.1E · higher_maurer_cartan_packets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.higher_maurer_cartan_packets`. Reflected implementation `komorebi_math.nonlinear.graded.higher_maurer_cartan_packets`. The same runtime object is also available through `komorebi_math.nonlinear.higher_maurer_cartan_packets`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(group: 'FiniteAbelianGroup', components: 'Mapping[str, Any]', operations: 'Mapping[int,
    ↪ GradedOperationCallable]', *, exactness: 'Exactness' = <Exactness.NUMERICAL: 'numerical'>, tolerance:
    ↪ 'float' = 1e-10) -> 'HigherMaurerCartanResult'
```

Definition. Assemble a finite truncation `sum_r ell_r(eta^r)/r!` by labels.

Contract (D, C, H, R, X). Graded operations require a finite abelian grading group, finite component records, and multilinear operations whose declared output grade is the group sum of the input grades. Maurer Cartan routines evaluate only the supplied finite arity range. Divided square evaluation requires the supplied differential, bracket, and divided square maps to have compatible component shapes.

Guarantees (E, P, B, K). Grade bookkeeping and finite group arithmetic are exact. Numerical component values inherit the arithmetic of the supplied arrays and operations. Certificates compare the gradewise reconstruction

with the direct finite expression and record any failed compatibility law. No unspecified higher operation or infinite Maurer Cartan series is inferred. The provenance registry records `PSC-III-P20` as Finite truncated packet equations for higher operations. Its recorded status is `proved`. The provenance record notes that this result does not certify convergence of an infinite Maurer–Cartan series.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_graded.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `load_packet_jet_snapshot_stream`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.load_packet_jet_snapshot_stream`. Reflected implementation `komorebi_math.nonlinear.streaming.load_packet_jet_snapshot_stream`. The same runtime object is also available through `komorebi_math.nonlinear.load_packet_jet_snapshot_stream`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (`s`).

```
(path: 'str | os.PathLike[str]', *, max_coefficients: 'int' = 1000000, verify_chunks: 'bool' = True) ->
   ↪  'PacketJetSnapshot'
```

Definition. Load a complete stream into a conventional in-memory snapshot.

Contract (`D`, `C`, `H`, `R`, `X`). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (`E`, `P`, `B`, `K`). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Rooted-tree expansions and majorants (6 cards).

C.1E · `majorant_convergence`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.majorant_convergence`. Reflected implementation `komorebi_math.nonlinear.trees.majorant_convergence`. The same runtime object is also available through `komorebi_math.nonlinear.majorant_convergence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-ROOTED-TREES`.

Manifest signature (s).

```
(seed_norm: 'float', operation_norms: 'Mapping[int, float]', radius: 'float', *, tolerance: 'float' = 1e-12) ->
    ↪ 'MajorantConvergence'
```

Definition. Validate `phi(R)<=R` and `sum r*b_r*R^(r-1)<1`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records `PSC-III-T14` as Polynomial rooted-tree convergence certificate. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Defects, lifting, grading, and transport (27 cards).

C.1E · `maurer_cartan_packets`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.maurer_cartan_packets`. Reflected implementation `komorebi_math.nonlinear.graded.maurer_cartan_packets`. The same runtime object is also available through `komorebi_math.nonlinear.maurer_cartan_packets`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

    ↪ 'PacketJetSnapshotStreamReader'
```

Definition. Open one packet-jet stream with explicit incomplete-stream policy.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family.

The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Derivatives and composition (15 cards).

C.1E · packet_faa_di_bruno

Identity (q, a, t, k). Public research-manifest route `komorebi_math.packet_faa_di_bruno`. Reflected implementation `komorebi_math.nonlinear.composition.packet_faa_di_bruno`. The same runtime object is also available through `komorebi_math.nonlinear.packet_faa_di_bruno`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-DERIVATIVE`.

Manifest signature (s).

```
(outer: 'DerivativeProvider', inner: 'DerivativeProvider', point: 'Any', directions: 'Sequence[Any]', source:
    ↪ 'PacketSystem', intermediate: 'PacketSystem', target: 'PacketSystem', *, input_packets:
    ↪ 'Sequence[PacketLabel]', output_packet: 'PacketLabel', inner_support: 'Mapping[int, PacketJetSupport] |
    ↪ None' = None, outer_support: 'Mapping[int, PacketJetSupport] | None' = None, tolerance: 'float | None' =
    ↪ None, retain_terms: 'bool' = True, max_terms: 'int' = 1000000) -> 'FaaDiBrunoResult'
```

Definition. Evaluate one packet jet of a composition through decorated partitions.

Contract (D, C, H, R, X). Composition requires compatible inner and outer dimensions and derivative support through the requested order. The Faà di Bruno routines enumerate set partitions of the direction labels. Packet composition also requires compatible source, intermediate, and target packet systems. Partition utilities accept nonnegative finite orders and return canonical immutable records.

Guarantees (E, P, B, K). For the composition operations in this family, the computed derivative value equals the implemented finite Faà di Bruno sum for the supplied providers and directions. Exactness follows the participating providers. The composition result records retained terms, partition counts, and a certificate comparing the composed derivative with the direct implementation when that comparison is available. Enumeration grows according to Bell and Stirling counts, so callers must keep the derivative order bounded. The provenance registry records `PSC-III-T11A` as Packet Faà di Bruno formula. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_jets_composition.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · packet_jet_benchmark_contract

Identity (q, a, t, k). Public research-manifest route `komorebi_math.packet_jet_benchmark_contract`. Reflected implementation `komorebi_math.nonlinear.execution.packet_jet_benchmark_contract`. The same runtime object is also available through `komorebi_math.nonlinear.packet_jet_benchmark_contract`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', *, backend: 'str', timing_scope: 'str' = 'kernel') -> 'Any'
```

Definition. Create a matched benchmark contract without importing algorithms eagerly.

Contract (D, C, H, R, X). Execution plans require a finite packet-jet family and an optional support record for the same order and packet names. Only blocks certified zero may be pruned. Plan compilation enforces an explicit address budget. Execution requires one direction per derivative slot and checks that the plan still matches the family. CuPy execution additionally requires an importable CuPy runtime and a CUDA device.

Guarantees (E, P, B, K). The CPU planner groups active output blocks by common projected inputs, caches those projections, and reports derivative-call and projection counts. Reconstruction is compared with the direct represented

derivative. Optional CuPy classes preserve the same finite packet contract when the hardware boundary is available. Runtime discovery alone is not a performance or correctness qualification, and unavailable device paths fail explicitly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_execution.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Packet jets and sparse tensors (7 cards).

C.1E · packet_jet_support

Identity (q, a, t, k). Public research-manifest route `komorebi_math.packet_jet_support`. Reflected implementation `komorebi_math.nonlinear.jets.packet_jet_support`. The same runtime object is also available through `komorebi_math.nonlinear.packet_jet_support`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(family: 'PacketJetFamily', *, tolerance: 'float | None' = None, max_evaluations: 'int' = 100000) ->
    ↪ 'PacketJetSupport'
```

Definition. Classify packet jet blocks by exhaustive packet-range basis tests.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evaluation requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets.

Guarantees (E, P, B, K). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-C08` as Finite packet jet support test. Its recorded status is `finite certificate`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

C.1E · packet_taylor

Identity (q, a, t, k). Public research-manifest route `komorebi_math.packet_taylor`. Reflected implementation `komorebi_math.nonlinear.jets.packet_taylor`. The same runtime object is also available through `komorebi_math.nonlinear.packet_taylor`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-PACKET-JET`.

Manifest signature (s).

```
(provider: 'DerivativeProvider', point: 'Any', increment: 'Any', source: 'PacketSystem', target: 'PacketSystem',
    ↪ order: 'int', *, tolerance: 'float | None' = None) -> 'PacketTaylorResult'
```

Definition. Assemble a finite Taylor polynomial through packet jet reconstruction.

Contract (D, C, H, R, X). Packet jets require a derivative provider, compatible finite source and target packet systems, a valid base point, and a positive supported derivative order. Packet labels must resolve inside their systems. Evalua-

tion requires one source direction per input address. Support discovery and Taylor assembly also require positive finite tolerances and explicit evaluation budgets.

Guarantees (`E, P, B, K`). A packet jet evaluates the declared derivative after source projection and target projection. A complete family reconstructs the represented finite derivative when both packet systems are complete. Support classifications are exhaustive only when the evaluation budget covers every required packet basis probe. Taylor certificates compare one finite truncation with the observed map value at the supplied increment. Address counts and support work grow combinatorially with order and packet count. The provenance registry records `PSC-III-C09` as Finite packet Taylor reconstruction. Its recorded status is `finite certificate`. Recorded limitation: no automatic bound on the omitted Taylor remainder.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_jets_composition.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 38.

Rooted-tree expansions and majorants (6 cards).

C.1E · `packet_tree_reconstruction`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.packet_tree_reconstruction`. Reflected implementation `komorebi_math.nonlinear.trees.packet_tree_reconstruction`. The same runtime object is also available through `komorebi_math.nonlinear.packet_tree_reconstruction`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-ROOTED-TREES`.

Manifest signature (`s`).

```
(problem: 'PolynomialFixedPointProblem', tree: 'OrderedRootedTree', packets: 'PacketSystem', *, zero_support:
   ↪ 'Mapping[int, PacketJetSupport] | None' = None, tolerance: 'float | None' = None) -> 'PacketTreeResult'
```

Definition. Reconstruct one tree by summing packet labels at every vertex.

Contract (`D, C, H, R, X`). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (`E, P, B, K`). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity. The provenance registry records `PSC-III-T16` as Packet-labeled rooted-tree reconstruction. Its recorded status is `proved`.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · profile_operation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.profile_operation`. Reflected implementation `komorebi_math.nonlinear.profiling.profile_operation`. The same runtime object is also available through `komorebi_math.nonlinear.profile_operation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(name: 'str', operation: 'Callable[[], T]', *, repetitions: 'int' = 5, warmup: 'int' = 1, scope: 'str' = 'Python
   ↪  call including allocations and synchronization performed by the callable') -> 'RuntimeStageProfile'
```

Definition. Observe one callable without interpreting timings as asymptotic evidence.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · profile_packet_jet_runtime

Identity (q, a, t, k). Public research-manifest route `komorebi_math.profile_packet_jet_runtime`. Reflected implementation `komorebi_math.nonlinear.profiling.profile_packet_jet_runtime`. The same runtime object is also available through `komorebi_math.nonlinear.profile_packet_jet_runtime`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(family: 'PacketJetFamily', directions: 'Sequence[Any]', *, support: 'PacketJetSupport | None' = None, jet:
   ↪  'PacketJet | None' = None, repetitions: 'int' = 5, warmup: 'int' = 1, max_addresses: 'int' = 1000000,
   ↪  max_snapshot_evaluations: 'int' = 100000, include_stream_write: 'bool' = False, stream_chunk_size: 'int' =
   ↪  1024) -> 'PacketJetProfileReport'
```

Definition. Profile selected packet-jet stages under one explicit local contract.

Contract (D, C, H, R, X). Complexity estimation requires a finite family and a compatible optional support record or execution plan. Runtime profiles require positive repetition counts, nonnegative warmup counts, and a precisely stated measurement scope. Packet-jet profiling may include planning, execution, snapshot capture, and optional stream writing under explicit budgets.

Guarantees (E, P, B, K). Deterministic estimate fields are exact finite counts derived from the represented dimensions, packets, addresses, and plan. Timing and traced Python allocation samples are environment-dependent observations. They are not asymptotic evidence and do not include unreported device allocation or external process cost. Reports retain the interpreter, platform, scope, repetitions, and certificate needed to interpret the measurements. The provenance registry records `PSC-III-A61` as Finite packet-jet execution profile. Its recorded status is `heuristic`. Recorded limitations state that timings are environment dependent and that tracemalloc observes Python-managed allocations rather than total device or process memory.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block11_golden_profiling_beta.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

Rooted-tree expansions and majorants (6 cards).

C.1E · `quadratic_catalan_majorant`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.quadratic_catalan_majorant`. Reflected implementation `komorebi_math.nonlinear.trees.quadratic_catalan_majorant`. The same runtime object is also available through `komorebi_math.nonlinear.quadratic_catalan_majorant`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-ROOTED-TREES`.

Manifest signature (s).

```
(seed_norm: 'float', bilinear_norm: 'float', *, tolerance: 'float' = 1e-12) -> 'MajorantConvergence'
```

Definition. Construct the sharp small-root majorant for `u=s+B(u,u)`.

Contract (D, C, H, R, X). Ordered-tree enumeration requires internal arities of at least two, nonnegative height or positive leaf targets, and an explicit tree budget. Polynomial fixed-point problems require a finite seed, compatible multilinear operations, and declared exactness and tolerance. Majorant routines require finite nonnegative norm bounds and a positive candidate radius.

Guarantees (E, P, B, K). Tree counts and finite enumerations are exact within the requested boundary. A tree expansion equals the matching finite Picard iterate under the implemented polynomial operations. A convergence certificate is issued only when the supplied scalar majorant maps the declared ball into itself and has contraction factor below one. Packet reconstruction prunes only addresses covered by supplied zero-support certificates. Enumeration can grow exponentially or faster with height and arity.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_trees.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 39.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `save_packet_jet_snapshot_stream`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.save_packet_jet_snapshot_stream`. Reflected implementation `komorebi_math.nonlinear.streaming.save_packet_jet_snapshot_stream`. The same runtime object is also available through `komorebi_math.nonlinear.save_packet_jet_snapshot_stream`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', path: 'str | os.PathLike[str]', *, chunk_size: 'int' = 1024, coefficient_budget:
    ↪ 'int | None' = None, resume: 'bool' = False, overwrite: 'bool' = False) -> 'PacketJetStreamWriteResult'
```

Definition. Write an existing snapshot as independently verified coefficient chunks.

Contract (D, C, H, R, X). Chunked streams use fixed schema identifiers and version 1 envelopes. Writers require a destination, a positive chunk size, and explicit overwrite or resume policy. Direct capture writes to a partial directory and promotes it only after completion. Readers reject duplicate JSON keys, unsupported schemas, inconsistent ranges, digest mismatches, and incomplete streams unless incomplete access is explicitly allowed.

Guarantees (E, P, B, K). Each committed chunk has a payload digest and a manifest range. Resume continues only from a verified committed prefix. Selection and evaluation can operate with memory bounded by the configured chunk size. Loading a conventional snapshot requires a complete stream and an explicit coefficient ceiling. Digests provide integrity against accidental corruption, not authentication against an adversary able to replace the entire stream and its hashes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block11_streaming_migrations.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43.

C.1E · `snapshot_packet_jet`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.snapshot_packet_jet`. Reflected implementation `komorebi_math.nonlinear.snapshots.snapshot_packet_jet`. The same runtime object is also available through `komorebi_math.nonlinear.snapshot_packet_jet`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(jet: 'PacketJet', *, tolerance: 'float | None' = None, max_evaluations: 'int' = 100000) -> 'PacketJetSnapshot'
```

Definition. Capture one packet jet by exhaustive standard-basis evaluation.

Contract (D, C, H, R, X). A snapshot captures one fixed packet jet by evaluating the ambient standard-basis tuples through an explicit finite budget. The source and target dimensions, base point, address, provider name, exactness, and sparse coefficients are stored in the record. Snapshot evaluation requires direction vectors of the recorded source dimension.

Guarantees (E, P, B, K). The snapshot is provider-independent after capture and reconstructs the recorded multilinear block from its stored coefficients. Its comparison certificate checks matched evaluations against the source jet on supplied probes. Exact coefficients preserve exact arithmetic. Numerical coefficients use the stored tolerance and certificate. Dense capture cost grows as the source dimension raised to the jet order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_nonlinear_snapshots_persistence.py` and `tests/test_block10_execution_persistence.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapters 38 and 43.

Defects, lifting, grading, and transport (27 cards).

C.1E · `solve_mod_prime`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.solve_mod_prime`. Reflected implementation `komorebi_math.nonlinear.lifting.solve_mod_prime`. The same runtime object is also available through `komorebi_math.nonlinear.solve_mod_prime`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(matrix: 'Any', rhs: 'Any', prime: 'int') -> 'ModularLinearSolution'
```

Definition. Solve a finite linear system modulo a prime by exact row reduction.

Contract (D, C, H, R, X). Linear and polynomial lifting require a prime, a nonnegative depth, compatible finite equations, and a current residue class. One step searches the declared corrections modulo the prime. Tree construction requires an explicit terminal depth and a finite node budget.

Guarantees (E, P, B, K). For the lifting operations in this family, every returned child satisfies the represented congruence at the next prime power. Linear solves and branch verification are exact in modular arithmetic. Polynomial lifting uses the declared Jacobian and finite Taylor congruence. Branch counts may grow exponentially with depth, so the tree builder enforces the supplied node limit. The provenance registry records `PSC-III-LIN-FP` as Linear correction space over a prime field. Its recorded status is `classical input`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_lifting.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 40.

Execution, snapshots, streaming, and profiling (35 cards).

C.1E · `validate_cupy_snapshot`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.validate_cupy_snapshot`. Reflected implementation `komorebi_math.nonlinear.gpu.validate_cupy_snapshot`. The same runtime object is also available through `komorebi_math.nonlinear.validate_cupy_snapshot`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-EXECUTION`.

Manifest signature (s).

```
(snapshot: 'PacketJetSnapshot', probes: 'Sequence[Sequence[Any]]', *, tolerance: 'float' = 1e-09) ->
   ↪ 'CuPyValidationResult'
```

Definition. Compare matched CPU and CuPy evaluations on explicit probes.

Contract (D, C, H, R, X). GPU status inspection never requires hardware and returns the observed CuPy import and CUDA device state. Snapshot execution requires a complete finite snapshot, a working CuPy CUDA runtime, and compatible probe shapes. Validation compares the same persisted coefficients on CPU and device under a declared tolerance.

Guarantees (E, P, B, K). A successful validation record reports the probe count, maximum residual, runtime state, and certificate. The device executor evaluates only the captured finite snapshot and does not accept arbitrary Python callables. No speed claim follows from API presence. In a runtime without CuPy or a CUDA device, status reporting remains available while execution and validation are not hardware-qualified.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block16_gpu_qualification.py` and `tests/test_nonlinear_execution.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 43. The recorded reference environment had no CuPy CUDA device, so GPU evidence is limited to status reporting, explicit unavailability, and CPU-side contract checks.

Defects, lifting, grading, and transport (27 cards).

C.1E · `verify_finite_filtered_branch`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.verify_finite_filtered_branch`. Reflected implementation `komorebi_math.nonlinear.filtered.verify_finite_filtered_branch`. The same runtime object is also available through `komorebi_math.nonlinear.verify_finite_filtered_branch`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1E-NONLINEAR-CALCULUS`.

Manifest signature (s).

```
(source: 'FilteredVectorSpace', target: 'FilteredVectorSpace', map_function: 'Callable[[tuple[int, ...]],
    ↪ Sequence[int]]', approximations: 'Sequence[Sequence[int]]', *, start_depth: 'int' = 0) ->
    ↪ 'FiniteFilteredBranchResult'
```

Definition. Verify a compatible branch through a finite terminal filtration.

Contract (D, C, H, R, X). Filtered contracts require finite dimensional vector spaces over an explicit prime field and decreasing filtration bases with compatible ambient dimensions. Filtered correction is solved one finite depth at a time. A filtered cochain complex requires explicit differentials that square to zero and preserve the declared filtration. Projective limit completion also requires external completeness hypotheses supplied by the caller.

Guarantees (E, P, B, K). Associated graded coordinates, correction cosets, finite branches, and spectral sequence pages are exact over the represented finite field. The terminal finite filtration permits exact page dimension and stabilization checks. A projective limit record only stores the declared infinite hypotheses and finite compatibility evidence. It does not prove completeness or convergence beyond those assumptions.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_nonlinear_filtered.py`. The independent verifier for nonlinear facades checks root-to-domain object identity, reflected signature, implementation ownership, alias behavior, and representative CPU-safe execution for this facade family. The source validator for nonlinear facades checks exact card order, record counts, unique anchors, and preservation of the reference cards and formulas. See Chapter 42.

Related reference: packet jets, execution, streaming, and rooted trees. The 69 domain-namespace cards are collected in Section C.5B. The following overview explains their scope.

The nonlinear facade contracts include the following public operations. They cover packet-jet addresses, families, support and Taylor reconstruction, sparse symmetric tensors, projection-cached execution, finite snapshots, resumable streams, optional GPU boundaries, observational profiling, and ordered rooted-tree expansions.

Contract family	Cards
Packet jets, supports, and Taylor reconstruction	8
Sparse symmetric tensors	3
Projection-cached and optional CuPy execution	12
Portable packet-jet snapshots	3
Resumable chunked streams and schemas	14
Persisted-snapshot GPU validation	6
Complexity estimates and observational profiles	7
Ordered rooted trees and fixed-point expansions	14
Namespace availability records	2
Total	**69**

The boundary remains finite and explicit. Packet support is certified only over the tested packet bases. Snapshots and streams preserve one captured finite multilinear block. Timing records describe one local environment. GPU contracts require actual CuPy and CUDA availability before device execution can be qualified. Rooted-tree convergence remains conditional on the supplied scalar majorant and contraction inequalities.

C.1F Root generating, signal, and export facades: 62 entries

This root section documents top-level routes for three domain namespaces. The generating cards expose formal-series, basis, automaton, Mahler-mask, Bell-reduction, and prime-power arithmetic contracts. The signal cards expose packet trees, filter banks, polyphase analysis, singular packets, and finite jump recovery. The export cards expose the document model, renderers, portable persistence, serialization, reports, and file-writing interfaces.

Contract family	Cards
Generating functions and arithmetic	21

Contract family	Cards
Signal systems and recovery	7
Document model and rendering	10
Portable persistence and serialization	13
Export writers and reports	11
Total	**62**

These root routes do not create second implementations. Every card requires the root object to be identical to its domain route and to resolve to the implementation owner committed in the research manifest. File-writing and LaTeX contracts retain their explicit filesystem, overwrite, engine, and resource boundaries. These reference records do not claim a new external-toolchain or platform qualification.

Generating functions and arithmetic (21 cards).

C.1F · `BellParityAutomaton`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.BellParityAutomaton`. Reflected implementation `komorebi_math.generating.bell.BellParityAutomaton`. The same runtime object is also available through `komorebi_math.generating.BellParityAutomaton`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
(outputs: 'tuple[int, int, int]' = (1, 1, 0)) -> None
```

Definition. The three-state binary automaton for generalized Bell parity.

Contract (`D`, `C`, `H`, `R`, `X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction. The principal public operations are `transition`, `evaluate`.

Guarantees (`E`, `P`, `B`, `K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 22, 24, and 26.

C.1F · `BellResidueAutomaton`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.BellResidueAutomaton`. Reflected implementation `komorebi_math.generating.bell.BellResidueAutomaton`. The same runtime object is also available through `komorebi_math.generating.BellResidueAutomaton`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(prime: 'int', factorial_power: 'int', period_bound: 'int', outputs: 'tuple[int, ...]') -> None
```

Definition. A finite digit-sum automaton for factorial-power Bell residues.

Contract (D, C, H, R, X). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction. The principal public operations are `compile`, `transition`, `evaluate`, `certificate`.

Guarantees (E, P, B, K). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 22, 24, and 26.

C.1F · `CustomFunctionSpec`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CustomFunctionSpec`. Reflected implementation `komorebi_math.generating.functions.CustomFunctionSpec`. The same runtime object is also available through `komorebi_math.generating.CustomFunctionSpec`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(name: 'str', basis: 'WeightedMonomialBasis', builder: 'CoefficientBuilder', source_kind: 'str' = 'custom',
    ↪ metadata: 'Mapping[str, object]' = <factory>) -> None
```

Definition. A named exact coefficient source with an explicit basis and metadata.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names. The principal public operations are `series`.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21 through 24.

C.1F · FiniteMaskCarryPlan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteMaskCarryPlan`. Reflected implementation `komorebi_math.generating.masks.FiniteMaskCarryPlan`. The same runtime object is also available through `komorebi_math.generating.FiniteMaskCarryPlan`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(radix: 'int', mask: 'tuple[Fraction, ...]', carry_bound: 'int', matrices: 'tuple[Matrix, ...]') -> None
```

Definition. Exact carry-matrix representation of a finite local mask.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `dimension`, `evaluate`, `sequence`, `certificate`.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27 and 64.

C.1F · FiniteNormalizedSeries

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteNormalizedSeries`. Reflected implementation `komorebi_math.generating.finite_series.FiniteNormalizedSeries`. The same runtime object is also available through `komorebi_math.generating.FiniteNormalizedSeries`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', domain: 'CoefficientDomain[Any]', coefficients: 'Iterable[Any]', *, budget:
    ↪ 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000,
    ↪ maximum_matrix_dimension=4096, maximum_reachable_states=100000, maximum_local_combinations=1000000,
    ↪ maximum_modulus=2000000, maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'None'
```

Definition. A finite exact series `sum a_n z^n/gamma_n` over one domain.

Contract (D, C, H, R, X). The basis, coefficient domain, and budget must satisfy their public protocols. Coefficients are coerced into the declared domain. Binary operations require matching domains and compatible bases. Reciprocal requires a unit constant coefficient. Composition, exponential, and logarithm impose the same constant term conditions as ordinary formal calculus. Conversion returns an explicit finite transfer certificate. The principal public operations are `add`, `subtract`, `multiply`, `reciprocal`, `compose`, `exp`, `log`, `project`, `convert`, `certificate`.

Guarantees (E, P, B, K). Results are exact in the selected coefficient domain and bounded by the supplied `Generating Budget`. A valid transfer certificate checks reconstruction coefficient by coefficient through the stored degree. Complexity follows finite polynomial arithmetic, with quadratic convolution and potentially cubic composition at the truncation boundary.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families.

The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 22, and 61.

C.1F · FormalSeries

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FormalSeries`. Reflected implementation `komorebi_math.generating.series.FormalSeries`. The same runtime object is also available through `komorebi_math.generating.FormalSeries`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', coefficients: 'Iterable[int | Fraction]') -> 'None'
```

Definition. A finite exact series `sum a_n z^n/gamma_n`.

Contract (D, C, H, R, X). The coefficient tuple is finite and nonempty. Binary operations require compatible basis semantics or an explicit conversion. Reciprocal requires a nonzero constant term. Composition requires an inner zero constant term. Formal exponential requires zero constant term, while formal logarithm requires constant term one. Projectors and packets validate modulus and residue addresses. The principal public operations are `add`, `subtract`, `multiply`, `reciprocal`, `compose`, `exp`, `log`, `project`, `packet`, `convert`, `evaluate`.

Guarantees (E, P, B, K). Every algebraic result is exact over rational coefficients at the requested finite truncation. Multiplication, composition, reciprocal, exponential, and logarithm are finite formal operations and do not assert analytic convergence. Naive multiplication is quadratic in truncation degree, while composition and repeated powers can require cubic work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 22, and 24.

C.1F · FrozenGeneratingFunction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FrozenGeneratingFunction`. Reflected implementation `komorebi_math.generating.portable.FrozenGeneratingFunction`. The same runtime object is also available through `komorebi_math.generating.FrozenGeneratingFunction`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(name: 'str', basis_name: 'str', normalization: 'tuple[Fraction, ...]', coefficients: 'tuple[Fraction, ...]',
   ↪ source_kind: 'str', metadata: 'Mapping[str, Any]' = <factory>) -> None
```

Definition. Provider-independent finite snapshot of a custom generating function.

Contract (D, C, H, R, X). A frozen function requires nonempty names, a nonempty coefficient prefix, normalization of equal length beginning with one, no zero normalization values, and portable metadata. Reconstruction cannot exceed the captured degree. Freezing accepts only `CustomFunctionSpec`. Codec registration installs closed data only decoders and does not permit arbitrary Python object construction. The principal public operations are `degree`, `series`.

Guarantees (E, P, B, K). The frozen record preserves exact rational coefficients and basis normalization independently of the original callback. Roundtrip integrity is delegated to the project portable envelope and its digest checks. Serialization cost is linear in the captured prefix, subject to the global payload budget used by the persistence layer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families.

The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 61, and 72.

C.1F · `FunctionRegistry`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.FunctionRegistry`. Reflected implementation `komorebi_math.generating.functions.FunctionRegistry`. The same runtime object is also available through `komorebi_math.generating.FunctionRegistry`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
() -> 'None'
```

Definition. An explicit custom-function registry. Names cannot silently overwrite existing entries.

Contract (`D, C, H, R, X`). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names. The principal public operations are `register`, `get`, `names`.

Guarantees (`E, P, B, K`). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21 through 24.

C.1F · `GeneratingBudget`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.GeneratingBudget`. Reflected implementation `komorebi_math.generating.budget.GeneratingBudget`. The same runtime object is also available through `komorebi_math.generating.GeneratingBudget`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
(maximum_degree: 'int' = 100000, maximum_coefficient_bits: 'int' = 4000000, maximum_matrix_dimension: 'int' = 4096,
    ↪ maximum_reachable_states: 'int' = 100000, maximum_local_combinations: 'int' = 1000000, maximum_modulus:
    ↪ 'int' = 2000000, maximum_serialized_bytes: 'int' = 67108864, maximum_recursion_depth: 'int' = 1000) -> None
```

Definition. Upper bounds checked before potentially expensive operations.

Contract (`D, C, H, R, X`). Every stored limit must be a positive integer. Degree, term, matrix, state, modulus, serialized size, and coefficient bit checks reject malformed requests before the corresponding expansion or allocation begins. The default object is immutable. Exceeding a declared limit raises `ResourceLimitError`, while malformed values raise `ValidationError`. The principal public operations are `require_degree`, `require_terms`, `require_matrix_dimension`, `require_states`, `require_local_combinations`, `require_modulus`, `require_serialized_bytes`, `require_coefficient_bits`.

Guarantees (`E, P, B, K`). The budget performs deterministic scalar validation and does not estimate hidden backend memory. Its checks are constant time. A caller who supplies a larger budget accepts the resulting exact arithmetic, state enumeration, and serialization costs.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 23, and 64.

C.1F · NormalizedBasis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.NormalizedBasis`. Reflected implementation `komorebi_math.generating.basis.WeightedMonomialBasis`. The same runtime object is also available through `komorebi_math.generating.NormalizedBasis`. The public export name maps to implementation object `WeightedMonomialBasis`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(name: 'str', gamma: 'GammaRule', *, descriptor: 'BasisDescriptor | None' = None) -> 'None'
```

Definition. A basis `e_n(z)=z^n/gamma_n` with `gamma_0=1`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor. The principal public operations are `gamma`, `lowering_weight`, `structure_constant`, `packet_transfer_weight`, `finite_certificate`, `require_descriptor`.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 22, and 24.

C.1F · PrimePowerKernelCompiler

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PrimePowerKernelCompiler`. Reflected implementation `komorebi_math.generating.padic_units.PrimePowerKernelCompiler`. The same runtime object is also available through `komorebi_math.generating.PrimePowerKernelCompiler`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(prime: 'int', exponent: 'int', factorial_power: 'int', unit_sequence: 'Callable[[int], int] | None' = None,
    ↪  max_modulus: 'int' = 2000000) -> None
```

Definition. Compile kernels for `gamma_n=c**n (n!)**s u_n` modulo `p**r`. The geometric factor cancels from every structure constant. The supplied `unit_sequence` must take values coprime to `p`.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required. The principal public operations are `modulus`, `kernel`.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal,

and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27.

C.1F · `WeightedMonomialBasis`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.WeightedMonomialBasis`. Reflected implementation `komorebi_math.generating.basis.WeightedMonomialBasis`. The same runtime object is also available through `komorebi_math.generating.WeightedMonomialBasis`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
(name: 'str', gamma: 'GammaRule', *, descriptor: 'BasisDescriptor | None' = None) -> 'None'
```

Definition. A basis `e_n(z)=z^n/gamma_n` with `gamma_0=1`.

Contract (`D, C, H, R, X`). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor. The principal public operations are `gamma`, `lowering_weight`, `structure_constant`, `packet_transfer_weight`, `finite_certificate`, `require_descriptor`.

Guarantees (`E, P, B, K`). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 22, and 24.

C.1F · `compile_finite_mask_carry_plan`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.compile_finite_mask_carry_plan`. Reflected implementation `komorebi_math.generating.masks.compile_finite_mask_carry_plan`. The same runtime object is also available through `komorebi_math.generating.compile_finite_mask_carry_plan`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
(mask: 'Iterable[Scalar]', radix: 'int', *, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'FiniteMaskCarryPlan'
```

Definition. Compile `T_d(q,q')=r_(d+radix*q'-q)` for a finite mask.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27 and 64.

C.1F · `compile_rational_mask_automaton`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compile_rational_mask_automaton`. Reflected implementation `komorebi_math.generating.cartier.compile_rational_mask_automaton`. The same runtime object is also available through `komorebi_math.generating.compile_rational_mask_automaton`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(numerator: 'Sequence[int]', denominator: 'Sequence[int]', prime: 'int', *, minimize: 'bool' = True, max_states:
    ↪ 'int' = 100000, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'CartierAutomaton'
```

Definition. Compile a rational Mahler mask into a coefficient automaton modulo `prime`. The degree-derived linear dimension and the reachable-state guard are checked before state exploration begins.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27.

C.1F · `factorial_power_basis`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.factorial_power_basis`. Reflected implementation `komorebi_math.generating.basis.factorial_power_basis`. The same runtime object is also available through `komorebi_math.generating.factorial_power_basis`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(power: 'int', *, name: 'str | None' = None) -> 'WeightedMonomialBasis'
```

Definition. Return `z^n/(n!)^power` for a positive integer power.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 22, and 24.

C.1F · `freeze_custom_function`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.freeze_custom_function`. Reflected implementation `komorebi_math.generating.portable.freeze_custom_function`. The same runtime object is also available through `komorebi_math.generating.freeze_custom_function`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(function: 'CustomFunctionSpec', degree: 'int', *, include_metadata: 'bool' = True) -> 'FrozenGeneratingFunction'
```

Definition. Capture one custom function into a finite provider-independent record.

Contract (D, C, H, R, X). A frozen function requires nonempty names, a nonempty coefficient prefix, normalization of equal length beginning with one, no zero normalization values, and portable metadata. Reconstruction cannot exceed the captured degree. Freezing accepts only `CustomFunctionSpec`. Codec registration installs closed data only decoders and does not permit arbitrary Python object construction.

Guarantees (E, P, B, K). The frozen record preserves exact rational coefficients and basis normalization independently of the original callback. Roundtrip integrity is delegated to the project portable envelope and its digest checks. Serialization cost is linear in the captured prefix, subject to the global payload budget used by the persistence layer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 61, and 72.

C.1F · `generalized_bell_digit_reduction`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.generalized_bell_digit_reduction`. Reflected implementation `komorebi_math.generating.bell.generalized_bell_digit_reduction`. The same runtime object is also available through `komorebi_math.generating.generalized_bell_digit_reduction`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(index: 'int', prime: 'int', factorial_power: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'BellDigitReduction'
```

Definition. Compute and certify the unweighted Bell digit theorem at one index.

Contract (D, C, H, R, X). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (E, P, B, K). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 22, 24, and 26.

C.1F · `mahler_mask_inverse`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.mahler_mask_inverse`. Reflected implementation `komorebi_math.generating.masks.mahler_mask_inverse`. The same runtime object is also available through `komorebi_math.generating.mahler_mask_inverse`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(series: 'Iterable[Scalar]', radix: 'int', degree: 'int | None' = None, *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'tuple[Fraction, ...]'
```

Definition. Recover the unique local mask `R(z)=F(z)/F(z**radix)`.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27 and 64.

C.1F · `mahler_mask_product`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.mahler_mask_product`. Reflected implementation `komorebi_math.generating.masks.mahler_mask_product`. The same runtime object is also available through `komorebi_math.generating.mahler_mask_product`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
(mask: 'Iterable[Scalar]', radix: 'int', degree: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'tuple[Fraction, ...]'
```

Definition. Return `prod_(j>=0) R(z**radix**j)` through `z**degree`. Only finitely many mask levels affect a finite truncation. Arithmetic uses exact `fractions.Fraction` values.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27 and 64.

C.1F · `ordinary_basis`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.ordinary_basis`. Reflected implementation `komorebi_math.generating.basis.ordinary_basis`. The same runtime object is also available through `komorebi_math.generating.ordinary_basis`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (`s`).

```
(*, name: 'str' = 'ordinary') -> 'WeightedMonomialBasis'
```

Definition. Return the ordinary generating-function basis `z^n`.

Contract (`D, C, H, R, X`). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (`E, P, B, K`). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 21, 22, and 24.

C.1F · q_binomial_valuation_decomposition

Identity (q, a, t, k). Public research-manifest route `komorebi_math.q_binomial_valuation_decomposition`. Reflected implementation `komorebi_math.generating.q_kummer.q_binomial_valuation_decomposition`. The same runtime object is also available through `komorebi_math.generating.q_binomial_valuation_decomposition`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-GENERATING`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', base: 'int', prime: 'int') -> 'QKummerDecomposition'
```

Definition. Return the exact mixed-radix valuation decomposition. If `prime` divides `base`, every Gaussian binomial is a unit modulo `prime` and the valuation is zero. For an odd prime coprime to `base`, the block length is `ord_prime(base)` and the usual order-block formula applies. For `prime == 2` and odd `base`, the block length is two and the lift constant is `v_2(base + 1)`.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 24 through 27.

Signal systems and recovery (7 cards).

C.1F · HaarPacketTree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.HaarPacketTree`. Reflected implementation `komorebi_math.signals.wavelets.HaarPacketTree`. The same runtime object is also available through `komorebi_math.signals.HaarPacketTree`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(signal: 'np.ndarray', depth: 'int', normalized: 'bool', _nodes: 'dict[str, np.ndarray]') -> None
```

Definition. All Haar packet coefficients through one finite binary depth.

Contract (D, C, H, R, X). Haar packet trees require a finite nonempty one-dimensional signal, a nonnegative depth, and a length divisible by the corresponding power of two. Packet paths contain only binary branches. A pruning must cover the full tree without ancestor and descendant conflicts. Additive cost functions must return finite values. Lp exponents must be positive and finite where required. Principal public operations and properties are `analyze`, `decompose`, `nodes`, `coefficients`, `coefficient`, `paths_at_depth`, `full_leaves`, `validate_pruning`, `reconstruct`, `energy`, `reconstruction_certificate`, `certificate`. Additional public members are recorded in the machine-readable inventory.

Guarantees (E, P, B, K). Normalized Haar packet analysis preserves finite energy to numerical tolerance. Synthesis from a valid full tree or pruning reconstructs the supplied record under the stored tolerance. Best-basis selection is exact dynamic programming for the declared additive node cost. Tree construction and best-basis work scale with the number of stored coefficients across levels. The provenance registry records `PSC-V-D12` as Finite Haar packet tree. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 35.

C.1F · PeriodicFilterBank

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PeriodicFilterBank`. Reflected implementation `komorebi_math.signals.filterbanks.PeriodicFilterBank`. The same runtime object is also available through `komorebi_math.signals.PeriodicFilterBank`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(analysis_filters: 'Iterable[Any]', synthesis_filters: 'Iterable[Any]', decimation: 'int') -> 'None'
```

Definition. A finite periodic analysis and synthesis bank with explicit matrices.

Contract (D, C, H, R, X). Periodic and finite filter banks require compatible nonempty one-dimensional analysis and synthesis filters or compatible explicit matrices. Decimation factors must be positive, channel counts must agree, and periodic signal lengths must satisfy the declared divisibility rules. Lifting schemes require even finite records. Canonical dual construction requires full column rank. Numerical tolerances and matrix conventions remain part of the public contract. Principal public operations and properties are `channels`, `analysis_matrix`, `synthesis_matrix`, `analyze`, `synthesize`, `reconstruction_operator`, `perfect_reconstruction_certificate`, `frame_bounds`, `canonical_synthesis_matrix`, `reconstruction_error_bound`.

Guarantees (E, P, B, K). Analysis, synthesis, frame bounds, and reconstruction reports are finite linear-algebra computations. Perfect-reconstruction certificates compare the implemented finite operator with the identity under the stored tolerance. Haar and five-three lifting constructions use the documented normalization and periodic boundary law. Dense matrix construction, singular values, and pseudoinverses can require quadratic storage and cubic factorization cost. The provenance registry records `PSC-V-D08` as Finite periodic filter bank. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 35.

C.1F · PolyphaseSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PolyphaseSystem`. Reflected implementation `komorebi_math.signals.polyphase.PolyphaseSystem`. The same runtime object is also available through `komorebi_math.signals.PolyphaseSystem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(order: 'int', axis: 'int' = -1) -> None
```

Definition. A reusable polyphase analysis and synthesis system along one axis.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride. Principal public operations and properties are `analyze`, `synthesize`, `certificate`.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 14 and 35.

C.1F · `SingularPacket1D`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SingularPacket1D`. Reflected implementation `komorebi_math.signals.singular_packets.SingularPacket1D`. The same runtime object is also available through `komorebi_math.signals.SingularPacket1D`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(components: 'Iterable[TruncatedPowerTerm]') -> 'None'
```

Definition. A finite sum of truncated power terms.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity. Principal public operations and properties are `from_jumps`, `evaluate`, `remove`, `restore`, `trace_jumps`.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost. The provenance registry records `PSC-V-D16` as Finite one dimensional singular packet. Its recorded status is `definition`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 36.

C.1F · `polyphase_analyze`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.polyphase_analyze`. Reflected implementation `komorebi_math.signals.polyphase.polyphase_analyze`. The same runtime object is also available through `komorebi_math.signals.polyphase_analyze`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(signal: 'Any', order: 'int', *, axis: 'int' = -1, copy: 'bool' = True) -> 'PolyphaseCoordinates'
```

Definition. Split a finite array into residue channels along `axis`.

Contract (D, C, H, R, X). Polyphase orders, strides, and radices must be positive integers. Axis selections must be valid for the supplied array, and scalar arrays are rejected where an axis decomposition is required. Residue indices and mixed-radix addresses must lie in range. Lattice coordinates require one channel for every Cartesian residue address. Refinement requires exact divisibility of the fine stride by the coarse stride.

Guarantees (E, P, B, K). Analysis partitions the supplied finite array into explicit residue channels and synthesis restores their interleaving. Roundtrip certificates compare the restored array with the source under the stored tolerance. Mixed-radix addressing is least-significant digit first. Polyphase filtering exposes finite channel kernels with omitted coefficients treated as zero. Work and storage are linear in the represented array size plus the active kernel coefficients. The provenance registry records `PSC-V-T02` as Exact finite polyphase decomposition. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_signals_polyphase_filterbanks.py` and `tests/test_block15_polyphase_refinement.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 14 and 35.

C.1F · `recover_separated_jumps`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.recover_separated_jumps`. Reflected implementation `komorebi_math.signals.recovery.recover_separated_jumps`. The same runtime object is also available through `komorebi_math.signals.recover_separated_jumps`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(samples: 'Sequence[float]', *, spacing: 'float', lipschitz_bound: 'float', noise_bound: 'float', minimum_jump:
    ↪ 'float', threshold: 'float | None' = None, start: 'float' = 0.0, minimum_separation: 'float | None' = None)
    ↪ -> 'JumpRecoveryResult'
```

Definition. Recover jump cells by thresholding adjacent sample contrasts.

Contract (D, C, H, R, X). Scalar recovery requires a finite one-dimensional record with at least two samples. Spacing and minimum-jump parameters must be positive. Lipschitz and noise bounds must be nonnegative. The threshold gap must remain strict, and any minimum-separation value must be at least one sample spacing. Difference order is nonnegative and the finite step size is positive.

Guarantees (E, P, B, K). The recovery theorem is conditional on the stored smoothness, separation, and noise hypotheses. Finite differences and Haar formulas follow their explicit index and normalization conventions. Subgaussian bounds are finite confidence bounds for the declared sigma and delta. Candidate scanning is linear in sample count for fixed difference order. The provenance registry records `PSC-V-T36` as Stable recovery of separated one dimensional jumps. Its recorded status is `conditional theorem`. The provenance record restricts this claim to sampled signals in one dimension with separated value jumps.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_signals_recovery.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 36.

C.1F · retained_packet_reconstruct

Identity (q, a, t, k). Public research-manifest route `komorebi_math.retained_packet_reconstruct`. Reflected implementation `komorebi_math.signals.singular_packets.retained_packet_reconstruct`. The same runtime object is also available through `komorebi_math.signals.retained_packet_reconstruct`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-SIGNALS`.

Manifest signature (s).

```
(signal: 'Any', packet: 'Any', approximator: 'Callable[[np.ndarray], Any]', *, tolerance: 'float' = 1e-11) ->
    ↪ 'RetainedPacketResult'
```

Definition. Approximate only the packet removed component and restore the packet.

Contract (D, C, H, R, X). Truncated-power terms require finite locations and amplitudes with nonnegative integer order. Packet construction requires compatible term data. Reconstruction helpers require finite arrays of matching shape, and approximation matrices must have compatible dimensions. Region and location error helpers require nonnegative measures, compatible labels, and a positive finite exponent or infinity.

Guarantees (E, P, B, K). Singular packets evaluate, remove, and restore explicit truncated-power components. Retained-packet reconstruction records the smooth approximation, packet estimate, full reconstruction, and the exact finite error identity represented by those arrays. Location bounds are exact at jump order zero and use the documented mean-value estimate at positive orders. Runtime follows the number of samples times the number of retained terms plus any supplied approximation-matrix cost. The provenance registry records `PSC-V-T17` as Exact retained packet reconstruction identity. Its recorded status is `proved`.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_signals_wavelets_singular.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 36.

Document model and rendering (10 cards).

C.1F · DocumentMetadata

Identity (q, a, t, k). Public research-manifest route `komorebi_math.DocumentMetadata`. Reflected implementation `komorebi_math.export.model.DocumentMetadata`. The same runtime object is also available through `komorebi_math.export.DocumentMetadata`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(title: 'str' = 'Komorebi Math Export', author: 'str | None' = None, date: 'str | None' = None, abstract: 'str |
    ↪ None' = None, keywords: 'tuple[str, ...]' = ()) -> None
```

Definition. Metadata used by Markdown, HTML, and LaTeX document renderers.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent ver-

ifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 59.

C.1F · Equation

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Equation`. Reflected implementation `komorebi_math.export.model.Equation`. The same runtime object is also available through `komorebi_math.export.Equation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(latex: 'str', label: 'str | None' = None, numbered: 'bool' = False, description: 'str | None' = None) -> None
```

Definition. One LaTeX mathematical expression.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 59.

C.1F · LatexCompileOptions

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LatexCompileOptions`. Reflected implementation `komorebi_math.export.latex.LatexCompileOptions`. The same runtime object is also available through `komorebi_math.export.LatexCompileOptions`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(engine: 'LatexEngine | str' = <LatexEngine.AUTO: 'auto'>, passes: 'int' = 2, timeout: 'float' = 120.0,
    ↪ shell_escape: 'bool' = False, keep_auxiliary: 'bool' = False, jobname: 'str | None' = None) -> None
```

Definition. Options for one isolated LaTeX compilation.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for

generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60. The recorded reference environment exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.1F · LatexEngine

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LatexEngine`. Reflected implementation `komorebi_math.export.latex.LatexEngine`. The same runtime object is also available through `komorebi_math.export.LatexEngine`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(*values)
```

Definition. Enumeration of automatic, pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk compiler choices.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60. The recorded reference environment exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.1F · LatexRenderOptions

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LatexRenderOptions`. Reflected implementation `komorebi_math.export.renderers.LatexRenderOptions`. The same runtime object is also available through `komorebi_math.export.LatexRenderOptions`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(document_class: 'str' = 'article', class_options: 'tuple[str, ...]' = ('11pt',), packages: 'tuple[str, ...]' =
    ↪ ('amsmath', 'amssymb', 'booktabs', 'longtable', 'array', 'graphicx', 'hyperref', 'geometry', 'microtype'),
    ↪ include_table_of_contents: 'bool' = False, number_sections: 'bool' = True, geometry: 'str' = 'margin=1in')
    ↪ -> None
```

Definition. Configuration for generated LaTeX documents.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_export_renderers.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · `MathDocument`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MathDocument`. Reflected implementation `komorebi_math.export.model.MathDocument`. The same runtime object is also available through `komorebi_math.export.MathDocument`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(metadata: 'DocumentMetadata' = <factory>, blocks: 'list[DocumentBlock]' = <factory>) -> None
```

Definition. A renderer independent mathematical document.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods. Principal public operations and properties are `add`, `section`, `paragraph`, `equation`, `table`, `code`, `bullet_list`, `figure`.

Guarantees (E, P, B, K). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 59.

C.1F · `Table`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Table`. Reflected implementation `komorebi_math.export.model.Table`. The same runtime object is also available through `komorebi_math.export.Table`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(headers: 'tuple[str, ...]', rows: 'tuple[tuple[Any, ...], ...]', caption: 'str | None' = None, label: 'str | None'
   ↪  = None, alignment: 'tuple[str, ...] | None' = None) -> None
```

Definition. A rectangular table with optional caption and label.

Contract (D, C, H, R, X). Document records validate local structure at construction. Headings require nonempty text and levels from 1 through 6. Equations require nonempty LaTeX source. Tables must be rectangular and use one alignment entry per column when alignment is supplied. Lists must be nonempty. Figure paths are normalized, but

file existence is checked only by a writer. `MathDocument` appends validated blocks in order and returns itself from its fluent construction methods. Principal public operations and properties are `from_rows`.

Guarantees (`E`, `P`, `B`, `K`). The document model preserves block order and separates typed report structure from rendering. Block records are frozen, while the `MathDocument.blocks` list is a deliberate construction buffer. The model does not prove the truth of prose, equations, or certificate claims. `RawLatex` is trusted source and bypasses prose escaping only in the LaTeX renderer.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 59.

C.1F · `available_latex_engines`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.available_latex_engines`. Reflected implementation `komorebi_math.export.latex.available_latex_engines`. The same runtime object is also available through `komorebi_math.export.available_latex_engines`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-DOCUMENT`.

Manifest signature (`s`).

```
() -> 'dict[str, bool]'
```

Definition. Report which supported LaTeX commands are available on PATH.

Contract (`D`, `C`, `H`, `R`, `X`). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (`E`, `P`, `B`, `K`). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (`V`, `L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60. The recorded reference environment exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.1F · `compile_latex`

Identity (`q`, `a`, `t`, `k`). Public research-manifest route `komorebi_math.compile_latex`. Reflected implementation `komorebi_math.export.latex.compile_latex`. The same runtime object is also available through `komorebi_math.export.compile_latex`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(source: 'str | Path', output_dir: 'str | Path', *, options: 'LatexCompileOptions | None' = None, source_name:
    ↪  'str' = 'document.tex') -> 'LatexCompilation'
```

Definition. Compile LaTeX source to PDF without enabling shell escape by default.

Contract (D, C, H, R, X). LaTeX compilation resolves an explicit engine or the first installed automatic candidate. Pass counts and timeouts must be positive. Job names must be simple file names. Shell escape is disabled by default, direct engines receive `-no-shell-escape`, and the `latexmk` wrapper rejects shell-escape requests. Source may be an existing `.tex` path or text written into the isolated output directory.

Guarantees (E, P, B, K). The compilation record retains source, PDF, log, engine, commands, return codes, and a certificate. Success requires all invoked commands to return zero and a nonempty PDF to exist. Missing engines raise `BackendUnavailableError`. Compiler success is local environment evidence, not a proof that trusted raw LaTeX is safe or that every external asset remains available later.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60. The recorded reference environment exposed pdfLaTeX, XeLaTeX, LuaLaTeX, and latexmk, but engine availability remains an environment observation rather than a package guarantee.

C.1F · `render_latex`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.render_latex`. Reflected implementation `komorebi_math.export.renderers.render_latex`. The same runtime object is also available through `komorebi_math.export.render_latex`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-DOCUMENT`.

Manifest signature (s).

```
(document: 'MathDocument', *, options: 'LatexRenderOptions | None' = None) -> 'str'
```

Definition. Render a complete compilable LaTeX document.

Contract (D, C, H, R, X). Renderers consume one `MathDocument` without modifying it. Ordinary prose, metadata, table cells, labels, and captions are escaped for the target format. Equation bodies and `RawLatex` remain trusted mathematical source. HTML can include an optional MathJax loader. LaTeX options validate document-class and package names before they enter the preamble.

Guarantees (E, P, B, K). Each renderer returns a complete text representation with the original block order. Markdown, HTML, text, and LaTeX outputs are semantically related but are not expected to be byte-identical. Rendering performs no filesystem write and no LaTeX compilation. The HTML MathJax option adds a network reference rather than bundling MathJax locally.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_export_renderers.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

Portable persistence and serialization (13 cards).

C.1F · PortableCodec

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PortableCodec`. Reflected implementation `komorebi_math.export.persistence.PortableCodec`. The same runtime object is also available through `komorebi_math.export.PortableCodec`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(tag: 'str', version: 'int', type_: 'type[Any]', encoder: 'Encoder', decoder: 'Decoder') -> None
```

Definition. One explicit type codec in the portable persistence registry.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · PortableMigration

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PortableMigration`. Reflected implementation `komorebi_math.export.persistence.PortableMigration`. The same runtime object is also available through `komorebi_math.export.PortableMigration`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(tag: 'str', from_version: 'int', to_version: 'int', migrator: 'Migrator') -> None
```

Definition. One explicit, adjacent codec-data migration.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`,

tests/test_block11_streaming_migrations.py, and tests/test_nonlinear_snapshots_persistence.py. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · dumps_portable

Identity (q, a, t, k). Public research-manifest route komorebi_math.dumps_portable. Reflected implementation komorebi_math.export.persistence.dumps_portable. The same runtime object is also available through komorebi_math.export.dumps_portable. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind function. Profile C1F-PORTABLE.

Manifest signature (s).

```
(value: 'Any', *, indent: 'int | None' = 2, max_depth: 'int' = 128) -> 'str'
```

Definition. Serialize one value into a complete digest-checked JSON envelope.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. save_portable writes and flushes a temporary sibling before os.replace, while load_portable delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are tests/test_block15_persistence.py, tests/test_block10_execution_persistence.py, tests/test_block11_streaming_migrations.py, and tests/test_nonlinear_snapshots_persistence.py. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · from_serializable

Identity (q, a, t, k). Public research-manifest route komorebi_math.from_serializable. Reflected implementation komorebi_math.export.serialization.from_serializable. The same runtime object is also available through komorebi_math.export.from_serializable. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind function. Profile C1F-PORTABLE.

Manifest signature (s).

```
(value: 'Any', *, max_depth: 'int' = 64, _depth: 'int' = 0) -> 'Any'
```

Definition. Decode the safe built-in type markers emitted by to_serializable.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing Exportable. Recursion is bounded by max_depth. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by repr, and arbitrary class

names in `__type__` are never imported or instantiated. The adapter registry is process-local and a copied registry returned by `export_adapters` cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is `tests/test_export_serialization.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 59 and 60.

C.1F · `load_portable`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.load_portable`. Reflected implementation `komorebi_math.export.persistence.load_portable`. The same runtime object is also available through `komorebi_math.export.load_portable`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(path: 'str | os.PathLike[str]', *, max_depth: 'int' = 128) -> 'Any'
```

Definition. Read and validate a portable envelope from disk.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · `loads_portable`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.loads_portable`. Reflected implementation `komorebi_math.export.persistence.loads_portable`. The same runtime object is also available through `komorebi_math.export.loads_portable`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(text: 'str | bytes', *, max_depth: 'int' = 128) -> 'Any'
```

Definition. Validate and deserialize one complete portable JSON envelope.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · `portable_codecs`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.portable_codecs`. Reflected implementation `komorebi_math.export.persistence.portable_codecs`. The same runtime object is also available through `komorebi_math.export.portable_codecs`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
() -> 'tuple[PortableCodec, ...]'
```

Definition. Return the active codecs ordered by stable tag.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · `portable_digest`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.portable_digest`. Reflected implementation `komorebi_math.export.persistence.portable_digest`. The same runtime object is also available through `komorebi_math.export.portable_digest`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(value: 'Any', *, max_depth: 'int' = 128) -> 'str'
```

Definition. Return the canonical SHA256 digest of one encoded payload.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · portable_migrations

Identity (q, a, t, k). Public research-manifest route `komorebi_math.portable_migrations`. Reflected implementation `komorebi_math.export.persistence.portable_migrations`. The same runtime object is also available through `komorebi_math.export.portable_migrations`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
() -> 'tuple[PortableMigration, ...]'
```

Definition. Return registered codec migrations in deterministic order.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · register_portable_codec

Identity (q, a, t, k). Public research-manifest route `komorebi_math.register_portable_codec`. Reflected implementation `komorebi_math.export.persistence.register_portable_codec`. The same runtime object is also available through `komorebi_math.export.register_portable_codec`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(type_: 'type[T]', *, tag: 'str', version: 'int', encoder: 'Callable[[T], Any]', decoder: 'Callable[[Any], T]',
   ↪ replace: 'bool' = False) -> 'None'
```

Definition. Register one stable round-trip codec.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`, and `tests/test_nonlinear_snapshots_persistence.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · register_portable_migration

Identity (q, a, t, k). Public research-manifest route `komorebi_math.register_portable_migration`. Reflected implementation `komorebi_math.export.persistence.register_portable_migration`. The same runtime object is also available through `komorebi_math.export.register_portable_migration`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-PORTABLE`.

Manifest signature (s).

```
(*, tag: 'str', from_version: 'int', to_version: 'int', migrator: 'Migrator', replace: 'bool' = False) -> 'None'
```

Definition. Register one deterministic adjacent migration for codec data.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. `save_portable` writes and flushes a temporary sibling before `os.replace`, while `load_portable` delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_block15_persistence.py`, `tests/test_block10_execution_persistence.py`,

tests/test_block11_streaming_migrations.py, and tests/test_nonlinear_snapshots_persistence.py. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · save_portable

Identity (q, a, t, k). Public research-manifest route komorebi_math.save_portable. Reflected implementation komorebi_math.export.persistence.save_portable. The same runtime object is also available through komorebi_math.export.save_portable. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind function. Profile C1F-PORTABLE.

Manifest signature (s).

```
(value: 'Any', path: 'str | os.PathLike[str]', *, overwrite: 'bool' = False, indent: 'int | None' = 2, max_depth:
    ↪  'int' = 128) -> 'Path'
```

Definition. Atomically write a portable envelope to disk.

Contract (D, C, H, R, X). Portable persistence accepts finite JSON primitives, explicit structural tags, and registered codecs. Codec tags are nonempty and whitespace-free. Versions are positive integers. Migrations advance exactly one version at a time. The envelope has exactly five fields and binds the canonical encoded payload to SHA-256. Loading rejects duplicate JSON keys, nonfinite constants, unknown schemas, unsupported versions, digest mismatches, malformed tags, missing migration edges, and depth-limit violations.

Guarantees (E, P, B, K). Canonical payload ordering makes the digest deterministic for a fixed codec contract and value. Decoding never imports a class named by untrusted data. save_portable writes and flushes a temporary sibling before os.replace, while load_portable delegates all validation to the envelope decoder. SHA-256 provides integrity detection, not encryption, secrecy, or authentication. Extension codecs remain dynamic process state unless separately frozen by a release contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are tests/test_block15_persistence.py, tests/test_block10_execution_persistence.py, tests/test_block11_streaming_migrations.py, and tests/test_nonlinear_snapshots_persistence.py. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 61.

C.1F · to_serializable

Identity (q, a, t, k). Public research-manifest route komorebi_math.to_serializable. Reflected implementation komorebi_math.export.serialization.to_serializable. The same runtime object is also available through komorebi_math.export.to_serializable. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind function. Profile C1F-PORTABLE.

Manifest signature (s).

```
(value: 'Any', *, preserve_types: 'bool' = True, max_depth: 'int' = 64, _depth: 'int' = 0) -> 'Any'
```

Definition. Convert package and scientific Python objects to JSON compatible data.

Contract (D, C, H, R, X). Presentation serialization accepts supported Python primitives, NumPy values, fractions, complex values, paths, enums, package result records, dataclasses, mappings, sequences, registered adapters, and objects implementing Exportable. Recursion is bounded by max_depth. Registered adapters are selected through the runtime type MRO. Decoding reconstructs only the safe built-in markers emitted by this layer and leaves unknown type markers as ordinary mappings.

Guarantees (E, P, B, K). The result is JSON-compatible presentation data. Type preservation is selective rather than a general object-reconstruction promise. Mapping keys become strings, sets are ordered by repr, and arbitrary class

names in __type__ are never imported or instantiated. The adapter registry is process-local and a copied registry returned by export_adapters cannot mutate the active registry.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test module is tests/test_export_serialization.py. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapters 59 and 60.

Export writers and reports (11 cards).

C.1F · ExportBundleResult

Identity (q, a, t, k). Public research-manifest route komorebi_math.ExportBundleResult. Reflected implementation komorebi_math.export.writers.ExportBundleResult. The same runtime object is also available through komorebi_math.export.ExportBundleResult. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1F-EXPORT.

Manifest signature (s).

```
(path: 'Path', members: 'tuple[str, ...]', formats: 'tuple[ExportFormat, ...]', manifest_path: 'Path',
   ↪ certificate: 'Certificate') -> None
```

Definition. A ZIP bundle containing several exports and a hash manifest.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds MANIFEST.sha256. Principal public operations and properties are valid, require.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are tests/test_export_files.py and tests/test_export_cli.py. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · ExportFormat

Identity (q, a, t, k). Public research-manifest route komorebi_math.ExportFormat. Reflected implementation komorebi_math.export.writers.ExportFormat. The same runtime object is also available through komorebi_math.export.ExportFormat. The root route is governed by [RESEARCH] policy pre-beta-additive. This facade does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1F-EXPORT.

Manifest signature (s).

```
(*values)
```

Definition. Enumeration of the 11 supported on-disk formats: JSON, YAML, CSV, TSV, text, Markdown, HTML, LaTeX, PDF, NPY, and NPZ.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses

deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (`E, P, B, K`). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · `ExportOptions`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.ExportOptions`. Reflected implementation `komorebi_math.export.writers.ExportOptions`. The same runtime object is also available through `komorebi_math.export.ExportOptions`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-EXPORT`.

Manifest signature (`s`).

```
(title: 'str' = 'Komorebi Math Export', author: 'str | None' = None, date: 'str | None' = None, abstract: 'str |
    ↪ None' = None, overwrite: 'bool' = False, create_parents: 'bool' = True, preserve_types: 'bool' = True,
    ↪ json_indent: 'int' = 2, include_certificate: 'bool' = True, keep_tex: 'bool' = True, html:
    ↪ 'HtmlRenderOptions' = <factory>, latex: 'LatexRenderOptions' = <factory>, compiler: 'LatexCompileOptions' =
    ↪ <factory>) -> None
```

Definition. Common export behavior and renderer options.

Contract (`D, C, H, R, X`). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (`E, P, B, K`). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · `ExportResult`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.ExportResult`. Reflected implementation `komorebi_math.export.writers.ExportResult`. The same runtime object is also available through `komorebi_math.export.ExportResult`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(path: 'Path', format: 'ExportFormat', bytes_written: 'int', companion_files: 'tuple[Path, ...]', certificate:
   ↪ 'Certificate') -> None
```

Definition. One completed file export and its validation certificate.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`. Principal public operations and properties are `valid`, `require`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · `available_export_formats`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.available_export_formats`. Reflected implementation `komorebi_math.export.writers.available_export_formats`. The same runtime object is also available through `komorebi_math.export.available_export_formats`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
() -> 'tuple[str, ...]'
```

Definition. Return every supported public format name.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · document_from_data

Identity (q, a, t, k). Public research-manifest route `komorebi_math.document_from_data`. Reflected implementation `komorebi_math.export.report.document_from_data`. The same runtime object is also available through `komorebi_math.export.document_from_data`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(value: 'Any', *, title: 'str' = 'Komorebi Math Export', author: 'str | None' = None, date: 'str | None' = None,
    ↪ abstract: 'str | None' = None, include_certificate: 'bool' = True) -> 'MathDocument'
```

Definition. Create a readable mathematical document from common Python data.

Contract (D, C, H, R, X). Report builders convert certificates, finite sequences, and common Python data into the typed document model. Existing `MathDocument` values pass through unchanged. Result records may contribute their certificate when `include_certificate` is enabled. Mappings, short arrays, sequences, and dataclasses are converted to tables when possible, while unsupported table shapes fall back to normalized JSON code.

Guarantees (E, P, B, K). The builders preserve visible validity, exactness, tolerances, residuals, assumptions, and diagnostics when those fields exist. They produce readable reports rather than portable reconstruction records. A report can summarize evidence, but creating the report does not independently validate the source object or certificate.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 59.

C.1F · export_bundle

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export_bundle`. Reflected implementation `komorebi_math.export.writers.export_bundle`. The same runtime object is also available through `komorebi_math.export.export_bundle`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(value: 'Any', path: 'str | Path', *, base_name: 'str' = 'komorebi_export', formats: 'Sequence[ExportFormat | str]'
    ↪ = (<ExportFormat.JSON: 'json'>, <ExportFormat.MARKDOWN: 'markdown'>, <ExportFormat.LATEX: 'latex'>),
    ↪ options: 'ExportOptions | None' = None) -> 'ExportBundleResult'
```

Definition. Create a ZIP archive with several exports and a SHA256 manifest.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for

generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · export_data

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export_data`. Reflected implementation `komorebi_math.export.writers.export_data`. The same runtime object is also available through `komorebi_math.export.export_data`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(value: 'Any', path: 'str | Path', *, format: 'ExportFormat | str | None' = None, options: 'ExportOptions | None' =
    ↪ None) -> 'ExportResult'
```

Definition. Export one Python or Komorebi Math value to a selected file format.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · export_document

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export_document`. Reflected implementation `komorebi_math.export.writers.export_document`. The same runtime object is also available through `komorebi_math.export.export_document`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(document: 'MathDocument', path: 'str | Path', *, format: 'ExportFormat | str | None' = None, options:
    ↪ 'ExportOptions | None' = None) -> 'ExportResult'
```

Definition. Export one renderer independent mathematical document.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for

generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · export_many

Identity (q, a, t, k). Public research-manifest route `komorebi_math.export_many`. Reflected implementation `komorebi_math.export.writers.export_many`. The same runtime object is also available through `komorebi_math.export.export_many`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(value: 'Any', directory: 'str | Path', *, base_name: 'str', formats: 'Sequence[ExportFormat | str]', options:
    ↪  'ExportOptions | None' = None) -> 'tuple[ExportResult, ...]'
```

Definition. Export one value into several formats inside one directory.

Contract (D, C, H, R, X). Writers resolve one of the 11 public formats, enforce parent-directory and overwrite policy, localize figure files when needed, and install primary outputs through temporary files. YAML requires PyYAML. PDF export requires a supported local LaTeX engine. NPY and NPZ writes disable pickle. Multi-format export uses deterministic suffixes, while bundle export stages files, records SHA-256 values, normalizes ZIP timestamps, and adds `MANIFEST.sha256`.

Guarantees (E, P, B, K). A valid result certificate establishes that the primary output exists, is nonempty, and matches the observed byte count. Companion paths record localized assets, generated TeX, or compiler logs. A bundle manifest supports later integrity replay, but it is not a keyed signature and does not authenticate the archive against replacement of both data and manifest. Writer certificates do not certify the mathematical truth of rendered content.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_files.py` and `tests/test_export_cli.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 60.

C.1F · sequence_document

Identity (q, a, t, k). Public research-manifest route `komorebi_math.sequence_document`. Reflected implementation `komorebi_math.export.report.sequence_document`. The same runtime object is also available through `komorebi_math.export.sequence_document`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. This facade does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1F-EXPORT`.

Manifest signature (s).

```
(name: 'str', values: 'Sequence[Any]', *, strategy: 'str | None' = None, modulus: 'int | None' = None, author: 'str
    ↪  | None' = None) -> 'MathDocument'
```

Definition. Build a table report for one executable sequence.

Contract (D, C, H, R, X). Report builders convert certificates, finite sequences, and common Python data into the typed document model. Existing `MathDocument` values pass through unchanged. Result records may contribute their certificate when `include_certificate` is enabled. Mappings, short arrays, sequences, and dataclasses are converted to tables when possible, while unsupported table shapes fall back to normalized JSON code.

Guarantees (E, P, B, K). The builders preserve visible validity, exactness, tolerances, residuals, assumptions, and diagnostics when those fields exist. They produce readable reports rather than portable reconstruction records. A report can summarize evidence, but creating the report does not independently validate the source object or certificate.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root facade. The focused test modules are `tests/test_export_renderers.py` and `tests/test_export_files.py`. The independent verifier for generating, signal, and export facades checks root-to-domain object identity, reflected signatures, implementation ownership, and representative CPU-safe behavior for the documented facade families. The source validator for generating, signal, and export facades checks exact card order, record counts, unique anchors, and preservation of the reference cards, technical blocks, and formulas. See Chapter 59.

C.1G Root namespace closure: 106 entries

This root section documents every research export not covered by the six preceding root sections. It closes the arithmetic, sequence, analytic, refinement, quantum, dynamics, deformation, Langlands, registry, unified workflow, and package-data facades.

Contract family	Cards
Arithmetic and sequence systems	21
Analytic and refinement systems	23
Quantum and dynamical systems	19
Deformation and Langlands systems	34
Registry, unified workflow, and root data	9
Total	**106**

The root names remain aliases or direct exports of the implementation objects recorded in the committed research manifest. Nested Langlands objects are intentionally exported at the package root even when the umbrella `komorebi_math.langlands` module does not repeat the alias. The finite Langlands records and completion gates remain conditional, executable models. They do not assert a proof of the unrestricted global correspondence.

Arithmetic and sequence systems (21 cards).

C.1G · `AutomaticSequence`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AutomaticSequence`. Reflected implementation `komorebi_math.sequences.automatic.AutomaticSequence`. The same runtime object is also available through `komorebi_math.sequences.AutomaticSequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
(base: 'int', transitions: 'Iterable[Iterable[int]]', outputs: 'Iterable[Number]', *, initial_state: 'int' = 0,
   ↪ name: 'str' = 'automatic sequence') -> 'None'
```

Definition. A deterministic finite automaton with numeric output.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term. Public fields are `base`, `transitions`, `outputs`, `initial_state`, `name`. Principal public operations are `state_count`, `state`, `term`, `first`, `residue_model`, `to_sequence`, `certificate`.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_models.py`, `tests/test_sequences_execution.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · CompiledSequence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CompiledSequence`. Reflected implementation `komorebi_math.sequences.compiler.CompiledSequence`. The same runtime object is also available through `komorebi_math.sequences.CompiledSequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
(sequence: 'Sequence', strategy: 'str', certificate: 'Certificate', recurrence: 'LinearRecurrence | None' = None,
    ↪ automatic: 'AutomaticSequence | None' = None, holonomic: 'HolonomicRecurrence | None' = None) -> None
```

Definition. An executable sequence strategy with an explicit validation certificate.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term. Public fields are `sequence`, `strategy`, `certificate`, `recurrence`, `automatic`, `holonomic`. Principal public operations are `term`, `first`, `modulo`, `generating_function`.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_models.py`, `tests/test_sequences_execution.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · EulerLocalCoordinates

Identity (q, a, t, k). Public research-manifest route `komorebi_math.EulerLocalCoordinates`. Reflected implementation `komorebi_math.arithmetic.euler.EulerLocalCoordinates`. The same runtime object is also available through `komorebi_math.arithmetic.EulerLocalCoordinates`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(prime: 'int') -> None
```

Definition. Exact odd or dyadic local coordinates for signed Euler numbers.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion. Public fields are `prime`. Principal public operations are `is_dyadic`, `source`, `kernel`, `inverse_kernel`, `reconstruct`, `inverse_reconstruct_source`, `kernel_valuation`, `row_weight`, `formula_row_weight`, `sharp_modulus`, `truncate`, `certificate`.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_euler.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_recurrence.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · HolonomicRecurrence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.HolonomicRecurrence`. Reflected implementation `komorebi_math.sequences.holonomic.HolonomicRecurrence`. The same runtime object is also available through `komorebi_math.sequences.HolonomicRecurrence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
(polynomials: 'Iterable[Iterable[Rational]]', initial: 'Iterable[Rational]', *, name: 'str' = 'holonomic
   ↪ recurrence') -> 'None'
```

Definition. An exact recurrence `sum_j P_j(n) a[n+j] = 0`.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term. Public fields are `polynomials`, `initial`, `name`. Principal public operations are `order`, `coefficient`, `term`, `first`, `to_sequence`, `certificate`.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_models.py`, `tests/test_sequences_execution.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · HurwitzSeries

Identity (q, a, t, k). Public research-manifest route `komorebi_math.HurwitzSeries`. Reflected implementation `komorebi_math.arithmetic.hurwitz.HurwitzSeries`. The same runtime object is also available through `komorebi_math.arithmetic.HurwitzSeries`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(coefficients: 'Iterable[Number]', modulus: 'int | None' = None) -> 'None'
```

Definition. A finite exact or modular Hurwitz coefficient system.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion. Public fields are `coefficients`, `modulus`. Principal public operations are `degree`, `coefficient`, `truncate`, `multiply`, `inverse`, `evaluate_egf`, `identity`, `exponential_mode`.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_recurrence.py`, `tests/test_arithmetic_euler.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · LinearRecurrence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LinearRecurrence`. Reflected implementation `komorebi_math.arithmetic.recurrence.LinearRecurrence`. The same runtime object is also available through `komorebi_math.arithmetic.LinearRecurrence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(coefficients: 'Iterable[Number]', initial: 'Iterable[Number]', *, name: 'str | None' = None) -> 'None'
```

Definition. An exact constant coefficient recurrence.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion. Principal public operations are `order`, `companion_matrix`, `initial_state`, `term`, `term_mod`, `first`, `state`, `jump_matrix`, `residue_packet`, `period_mod`, `characteristic_polynomial`, `jump_characteristic_polynomial`, `certificate`.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_recurrence.py`, `tests/test_sequences_execution.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · MahlerSeries

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MahlerSeries`. Reflected implementation `komorebi_math.arithmetic.mahler.MahlerSeries`. The same runtime object is also available through `komorebi_math.arithmetic.MahlerSeries`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(coefficients: 'Iterable[Number]') -> 'None'
```

Definition. A finite expansion in the binomial polynomial basis.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion. Public fields are `coefficients`. Principal public operations are `degree`, `from_values`, `evaluate`, `first`, `difference`, `affine_subsequence`, `valuation_ledger`, `reconstruction_certificate`.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_mahler_polyphase.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_recurrence.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · Sequence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.Sequence`. Reflected implementation `komorebi_math.sequences.base.Sequence`. The same runtime object is also available through `komorebi_math.sequences.Sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
(evaluator: 'Callable[[int], Number]', *, name: 'str' = 'sequence', exact: 'bool' = True, metadata: 'dict[str, Any]
   ↪  | None' = None) -> 'None'
```

Definition. A cached lazy sequence indexed by nonnegative integers.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term. Principal public operations are `term`, `first`, `residue`, `modulo`, `map`.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · StandardWindow

Identity (q, a, t, k). Public research-manifest route `komorebi_math.StandardWindow`. Reflected implementation `komorebi_math.arithmetic.standard_windows.StandardWindow`. The same runtime object is also available through `komorebi_math.arithmetic.StandardWindow`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(prime: 'int', compression: 'int') -> None
```

Definition. A congruential inverse window with exact rational and residual coordinates.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion. Public fields are `prime`, `compression`. Principal public operations are `order`, `has_uniform_period`, `period`, `reduced_inverse`, `exact_coefficients`, `residues`, `rational_generating_function`, `minimum_period`, `certificate`.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_recurrence.py`, `tests/test_arithmetic_euler.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · `TruncatedPadic`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.TruncatedPadic`. Reflected implementation `komorebi_math.arithmetic.domains.TruncatedPadic`. The same runtime object is also available through `komorebi_math.arithmetic.TruncatedPadic`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ARITHMETIC`.

Manifest signature (`s`).

```
(prime: 'int', precision: 'int') -> None
```

Definition. Arithmetic modulo `prime**precision` with explicit local precision.

Contract (`D, C, H, R, X`). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion. Public fields are `prime`, `precision`. Principal public operations are `modulus`, `ring`, `normalize`, `is_unit`, `inverse`, `valuation`, `refine`, `coarsen`.

Guarantees (`E, P, B, K`). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_recurrence.py`, `tests/test_arithmetic_euler.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · `affine_mahler_kernel`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.affine_mahler_kernel`. Reflected implementation `komorebi_math.arithmetic.mahler.affine_mahler_kernel`. The same runtime object is also available through `komorebi_math.arithmetic.affine_mahler_kernel`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ARITHMETIC`.

Manifest signature (`s`).

```
(multiplier: 'int', shift: 'int', source_degree: 'int', target_degree: 'int') -> 'int'
```

Definition. Return the exact affine Mahler transfer kernel.

Contract (`D, C, H, R, X`). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion.

Guarantees (`E, P, B, K`). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_mahler_polyphase.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_recurrence.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · apery_sequence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.apery_sequence`. Reflected implementation `komorebi_math.sequences.catalog.apery_sequence`. The same runtime object is also available through `komorebi_math.sequences.apery_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
() -> 'Sequence'
```

Definition. Return the Apéry numbers for `zeta(3)` through their exact recurrence.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · compile_sequence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.compile_sequence`. Reflected implementation `komorebi_math.sequences.compiler.compile_sequence`. The same runtime object is also available through `komorebi_math.sequences.compile_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
(sequence: 'Sequence', *, sample_count: 'int' = 24, max_order: 'int | None' = 8) -> 'CompiledSequence'
```

Definition. Compile a sequence to a declared or detected finite execution model.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · fibonacci_recurrence

Identity (q, a, t, k). Public research-manifest route `komorebi_math.fibonacci_recurrence`. Reflected implementation `komorebi_math.arithmetic.recurrence.fibonacci_recurrence`. The same runtime object is also available through `komorebi_math.arithmetic.fibonacci_recurrence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ARITHMETIC`.

Manifest signature (`s`).

```
() -> 'LinearRecurrence'
```

Definition. Return the Fibonacci recurrence.

Contract (`D, C, H, R, X`). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion.

Guarantees (`E, P, B, K`). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_recurrence.py`, `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_euler.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · `fibonacci_sequence`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.fibonacci_sequence`. Reflected implementation `komorebi_math.sequences.catalog.fibonacci_sequence`. The same runtime object is also available through `komorebi_math.sequences.fibonacci_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (`s`).

```
() -> 'Sequence'
```

Definition. Return the Fibonacci sequence.

Contract (`D, C, H, R, X`). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (`E, P, B, K`). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · `get_sequence`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.get_sequence`. Reflected implementation `komorebi_math.sequences.catalog.get_sequence`. The same runtime object is also available through `komorebi_math.sequences.get_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (`s`).

```
(name: 'str') -> 'Sequence'
```

Definition. Return one built in sequence by a normalized name.

Contract (`D, C, H, R, X`). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (`E, P, B, K`). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · `motzkin_sequence`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.motzkin_sequence`. Reflected implementation `komorebi_math.sequences.catalog.motzkin_sequence`. The same runtime object is also available through `komorebi_math.sequences.motzkin_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (`s`).

```
() -> 'Sequence'
```

Definition. Return Motzkin numbers through an exact holonomic recurrence.

Contract (`D, C, H, R, X`). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (`E, P, B, K`). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · `padic_valuation`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.padic_valuation`. Reflected implementation `komorebi_math.arithmetic.valuation.padic_valuation`. The same runtime object is also available through `komorebi_math.arithmetic.padic_valuation`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(value: 'Rational', prime: 'int') -> 'int | float'
```

Definition. Return the exact `prime` adic valuation of an integer or rational.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_euler.py`, `tests/test_lattice_smith.py`, `tests/test_arithmetic_hurwitz_windows.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · `partition_sequence`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.partition_sequence`. Reflected implementation `komorebi_math.sequences.catalog.partition_sequence`. The same runtime object is also available through `komorebi_math.sequences.partition_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
() -> 'Sequence'
```

Definition. Return integer partition numbers.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

C.1G · `signed_euler_number`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signed_euler_number`. Reflected implementation `komorebi_math.arithmetic.euler.signed_euler_number`. The same runtime object is also available through `komorebi_math.arithmetic.signed_euler_number`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ARITHMETIC`.

Manifest signature (s).

```
(index: 'int') -> 'int'
```

Definition. Return one signed Euler number from the `sech` convention.

Contract (D, C, H, R, X). Indices, orders, precisions, and moduli must satisfy the bounds stated by the signature. Recurrence coefficients and initial values must have compatible lengths. Local and p-adic operations validate the prime, truncation depth, and denominator conditions before exact expansion.

Guarantees (E, P, B, K). Integer, rational, recurrence, and truncated p-adic calculations are exact within the declared finite order or precision. Coefficient size and execution cost can grow quickly with degree and p-adic depth.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_arithmetic_domains_valuation.py`, `tests/test_arithmetic_hurwitz_windows.py`, `tests/test_arithmetic_recurrence.py`, `tests/test_arithmetic_euler.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 25 and 64.

C.1G · `thue_morse_sequence`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.thue_morse_sequence`. Reflected implementation `komorebi_math.sequences.catalog.thue_morse_sequence`. The same runtime object is also available through `komorebi_math.sequences.thue_morse_sequence`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-SEQUENCES`.

Manifest signature (s).

```
() -> 'Sequence'
```

Definition. Return the zero one Thue Morse automatic sequence.

Contract (D, C, H, R, X). Sequence indices are nonnegative. Automata must have a finite deterministic transition table, one output per state, and a valid initial state. Holonomic and compiled models require enough initial data to determine every requested term.

Guarantees (E, P, B, K). A fixed model returns deterministic terms and certificates. Lazy caches may change memory use but not the mathematical value. Automatic models scale with the base-digit length, while recurrence and holonomic models scale with the requested index and order.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_sequences_execution.py`, `tests/test_sequences_models.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 26.

Analytic and refinement systems (23 cards).

C.1G · `CyclicDenominator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CyclicDenominator`. Reflected implementation `komorebi_math.analytic.zeros.CyclicDenominator`. The same runtime object is also available through `komorebi_math.analytic.CyclicDenominator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int') -> None
```

Definition. Executable distinguished cyclic denominator family.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance. Public fields are `order`. Principal public operations are `derivative`, `positive_zeros`, `zero_count`.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_appell_zeros.py`, `tests/test_analytic_cyclic_reciprocal.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `CyclicSectionFamily`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.CyclicSectionFamily`. Reflected implementation `komorebi_math.analytic.sections.CyclicSectionFamily`. The same runtime object is also available through `komorebi_math.analytic.CyclicSectionFamily`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', family: "Literal['transfer', 'signed']" = 'signed', scale: 'complex' = 1.0) -> None
```

Definition. One transfer or signed cyclic differential family.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance. Public fields are `order`, `family`, `scale`. Principal public operations are `evaluate`, `vector`, `fundamental_matrix`.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_cyclic_reciprocal.py`, `tests/test_analytic_appell_zeros.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `LatticePacketData`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LatticePacketData`. Reflected implementation `komorebi_math.refinement.lattices.LatticePacketData`. The same runtime object is also available through `komorebi_math.refinement.LatticePacketData`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(lattice_basis: 'Any', projectors: 'Any', *, prime: 'int', split_basis: 'Any | None' = None) -> 'None'
```

Definition. A rational packet decomposition measured against one integral lattice.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Principal public operations are `dimension`, `certificate`, `projector_in_lattice_basis`, `projector_weights`, `separation_weight`, `precision_delays`, `inclusion_matrix`, `gluing_module`, `gluing_weight_certificate`.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_lattice_smith.py`, `tests/test_linear_defects.py`, `tests/test_residue_crt.py`, `tests/test_refinement_towers.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `LinearRefinementDefect`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LinearRefinementDefect`. Reflected implementation `komorebi_math.refinement.defects.LinearRefinementDefect`. The same runtime object is also available through `komorebi_math.refinement.LinearRefinementDefect`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(coarsen: 'Any', fine_operator: 'Any', coarse_operator: 'Any', backend: 'str | LinearAlgebraBackend | None' =
    ↪ None) -> None
```

Definition. The intertwining defect `C T_f - T_c C`.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Public fields are `coarsen`, `fine_operator`, `coarse_operator`, `backend`. Principal public operations are `matrix`, `is_exact`, `power`, `polynomial`, `resolvent`, `exponential`.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_residue_crt.py`, `tests/test_refinement_towers.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `PacketRefinement`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PacketRefinement`. Reflected implementation `komorebi_math.refinement.towers.PacketRefinement`. The same runtime object is also available through `komorebi_math.refinement.PacketRefinement`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (`s`).

```
(coarse: 'PacketSystem', fine: 'PacketSystem', parent_of_fine: 'tuple[int, ...]') -> None
```

Definition. One exact refinement from a coarse packet system to a fine system.

Contract (`D, C, H, R, X`). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Public fields are `coarse`, `fine`, `parent_of_fine`. Principal public operations are `backend`, `children`, `parent`, `certificate`, `coarsen`, `refine`, `refine_operator`, `coarsen_operator`, `support_reflection`.

Guarantees (`E, P, B, K`). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_refinement_towers.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_residue_crt.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `RefinementTower`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.RefinementTower`. Reflected implementation `komorebi_math.refinement.towers.RefinementTower`. The same runtime object is also available through `komorebi_math.refinement.RefinementTower`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (`s`).

```
(refinements: 'tuple[PacketRefinement, ...] | list[PacketRefinement]') -> 'None'
```

Definition. A finite sequence of exact packet refinements.

Contract (`D, C, H, R, X`). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Principal public operations are `levels`, `refine`, `coarsen`, `descendant_address`, `certificate`.

Guarantees (`E, P, B, K`). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_refinement_towers.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_residue_crt.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `SmithCongruenceProblem`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.SmithCongruenceProblem`. Reflected implementation `komorebi_math.refinement.smith.SmithCongruenceProblem`. The same runtime object is also available through `komorebi_math.refinement.SmithCongruenceProblem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(matrix: 'Any', rhs: 'Any', *, prime: 'int', depth: 'int') -> 'None'
```

Definition. Solve `matrix * x = rhs` modulo a prime power.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Principal public operations are `solve`, `enumerate_solutions`.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_lattice_smith.py`, `tests/test_linear_defects.py`, `tests/test_residue_crt.py`, `tests/test_refinement_towers.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `WeightedTransferEdge`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.WeightedTransferEdge`. Reflected implementation `komorebi_math.refinement.weighted.WeightedTransferEdge`. The same runtime object is also available through `komorebi_math.refinement.WeightedTransferEdge`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(source: 'int', target: 'int', weight: 'int', operator: 'Any', name: 'str' = '') -> None
```

Definition. One packet supported transfer with a positive filtration weight.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Public fields are `source`, `target`, `weight`, `operator`, `name`.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_weighted_transfer.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_residue_crt.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `WeightedTransferGraph`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.WeightedTransferGraph`. Reflected implementation `komorebi_math.refinement.weighted.WeightedTransferGraph`. The same runtime object is also available through `komorebi_math.refinement.WeightedTransferGraph`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(packet_system: 'PacketSystem', diagonal: 'Any', edges: 'tuple[WeightedTransferEdge, ...] |
    ↪ list[WeightedTransferEdge]', *, backend: 'str | LinearAlgebraBackend | None' = None, prime: 'int | None' =
    ↪ None, validate_weights: 'bool' = True) -> 'None'
```

Definition. A packet diagonal operator plus weighted directed transfer blocks.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision. Principal public operations are `dimension`, `operator`, `diagonal_inverse`, `adjacency`, `paths_below_weight`, `minimum_path_weight`, `path_operator`, `truncated_inverse`, `exact_inverse_if_acyclic`, `is_acyclic`, `weighted_adjacency`, `transfer_series_matrix`.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_weighted_transfer.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_residue_crt.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `appell_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.appell_polynomial`. Reflected implementation `komorebi_math.analytic.appell.appell_polynomial`. The same runtime object is also available through `komorebi_math.analytic.appell_polynomial`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', residue: 'int', parameter: 'Number', degree: 'int', x: 'Number') -> 'Number'
```

Definition. Evaluate one congruential Appell polynomial.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_appell_zeros.py`, `tests/test_analytic_cyclic_reciprocal.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `common_refinement`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.common_refinement`. Reflected implementation `komorebi_math.refinement.towers.common_refinement`. The same runtime object is also available through `komorebi_math.refinement.common_refinement`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REFINEMENT`.

Manifest signature (`s`).

```
(left: 'PacketSystem', right: 'PacketSystem', *, names: 'tuple[str, ...] | None' = None) -> 'tuple[PacketSystem,
   ↪  PacketRefinement, PacketRefinement]'
```

Definition. Construct the common refinement of two commuting packet systems.

Contract (`D, C, H, R, X`). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision.

Guarantees (`E, P, B, K`). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_refinement_towers.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_residue_crt.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `crt_many`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.crt_many`. Reflected implementation `komorebi_math.refinement.crt.crt_many`. The same runtime object is also available through `komorebi_math.refinement.crt_many`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REFINEMENT`.

Manifest signature (`s`).

```
(residues: 'Iterable[int]', moduli: 'Iterable[int]') -> 'CRTAddress'
```

Definition. Combine a finite collection of pairwise coprime residues.

Contract (`D, C, H, R, X`). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision.

Guarantees (`E, P, B, K`). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_residue_crt.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_refinement_towers.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `crt_pair`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.crt_pair`. Reflected implementation `komorebi_math.refinement.crt.crt_pair`. The same runtime object is also available through `komorebi_math.refinement.crt_pair`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(a: 'int', modulus_a: 'int', b: 'int', modulus_b: 'int') -> 'CRTAddress'
```

Definition. Combine two coprime residue addresses.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_residue_crt.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_refinement_towers.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `cyclic_project_coefficients`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.cyclic_project_coefficients`. Reflected implementation `komorebi_math.analytic.cyclic.cyclic_project_coefficients`. The same runtime object is also available through `komorebi_math.analytic.cyclic_project_coefficients`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(coefficients: 'Sequence[Any]', order: 'int', residue: 'int') -> 'np.ndarray'
```

Definition. Keep coefficients whose indices equal one residue modulo `order`.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_cyclic_reciprocal.py`, `tests/test_analytic_appell_zeros.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `denominator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.denominator`. Reflected implementation `komorebi_math.analytic.sections.denominator`. The same runtime object is also available through `komorebi_math.analytic.denominator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', z: 'complex') -> 'complex'
```

Definition. Evaluate the distinguished signed denominator `D_order(z)`.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_cyclic_reciprocal.py`, `tests/test_arithmetic_euler.py`, `tests/test_block10_execution_persistence.py`, `tests/test_block11_streaming_migrations.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · positive_zero_string

Identity (q, a, t, k). Public research-manifest route `komorebi_math.positive_zero_string`. Reflected implementation `komorebi_math.analytic.zeros.positive_zero_string`. The same runtime object is also available through `komorebi_math.analytic.positive_zero_string`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', count: 'int', *, start: 'int' = 0, tolerance: 'float' = 1e-12, max_iterations: 'int' = 64) ->
   ↪ 'ZeroStringResult'
```

Definition. Compute positive real zero representatives from asymptotic seeds.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_appell_zeros.py`, `tests/test_analytic_cyclic_reciprocal.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · reciprocal_coefficients

Identity (q, a, t, k). Public research-manifest route `komorebi_math.reciprocal_coefficients`. Reflected implementation `komorebi_math.analytic.reciprocal.reciprocal_coefficients`. The same runtime object is also available through `komorebi_math.analytic.reciprocal_coefficients`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (`s`).

```
(order: 'int', parameter: 'Number', degree: 'int') -> 'tuple[Number, ...]'
```

Definition. Return `P[order,n](parameter)` for `0 <= n <= degree`.

Contract (`D, C, H, R, X`). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (`E, P, B, K`). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_appell_zeros.py`, `tests/test_analytic_cyclic_reciprocal.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `residue_analyze`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.residue_analyze`. Reflected implementation `komorebi_math.refinement.residue.residue_analyze`. The same runtime object is also available through `komorebi_math.refinement.residue_analyze`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REFINEMENT`.

Manifest signature (`s`).

```
(values: 'Any', modulus: 'int') -> 'ResidueCoordinates'
```

Definition. Split a one dimensional sequence into residue channels.

Contract (`D, C, H, R, X`). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision.

Guarantees (`E, P, B, K`). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_block15_persistence.py`, `tests/test_block15_polyphase_refinement.py`, `tests/test_residue_crt.py`, `tests/test_linear_defects.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `residue_packet_system`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.residue_packet_system`. Reflected implementation `komorebi_math.refinement.residue.residue_packet_system`. The same runtime object is also available through `komorebi_math.refinement.residue_packet_system`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REFINEMENT`.

Manifest signature (s).

```
(length: 'int', modulus: 'int', *, backend: 'str | LinearAlgebraBackend | None' = None, names: 'tuple[str, ...] |
    ↪ None' = None) -> 'PacketSystem'
```

Definition. Return diagonal projectors selecting coordinate residues modulo `modulus`.

Contract (D, C, H, R, X). Packet dimensions, lattice bases, transfer matrices, and residue systems must be compatible. CRT operations require valid moduli and compatible congruences. Prime-local records require a prime and finite precision.

Guarantees (E, P, B, K). Rational, integral, and finite-field refinement data are computed exactly. Certificates apply to the declared finite matrices, lattices, residues, and tower depth. Matrix and Smith-form costs grow with dimension and coefficient size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_residue_crt.py`, `tests/test_linear_defects.py`, `tests/test_lattice_smith.py`, `tests/test_refinement_towers.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 17 through 24.

C.1G · `signed_section`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signed_section`. Reflected implementation `komorebi_math.analytic.sections.signed_section`. The same runtime object is also available through `komorebi_math.analytic.signed_section`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', residue: 'int', z: 'complex', *, tolerance: 'float' = 1e-15, max_terms: 'int' = 512) -> 'complex'
```

Definition. Evaluate `sum (-1)^n z**(order*n+residue)/(order*n+residue)!`.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_cyclic_reciprocal.py`, `tests/test_analytic_appell_zeros.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `theta_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.theta_polynomial`. Reflected implementation `komorebi_math.analytic.appell.theta_polynomial`. The same runtime object is also available through `komorebi_math.analytic.theta_polynomial`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', degree: 'int', parameter: 'Number') -> 'Number'
```

Definition. Evaluate the transfer theta polynomial of one degree.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_appell_zeros.py`, `tests/test_analytic_cyclic_reciprocal.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `transfer_section`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.transfer_section`. Reflected implementation `komorebi_math.analytic.sections.transfer_section`. The same runtime object is also available through `komorebi_math.analytic.transfer_section`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (s).

```
(order: 'int', residue: 'int', z: 'complex', *, scale: 'complex' = 1.0, tolerance: 'float' = 1e-15, max_terms:
    ↪  'int' = 512) -> 'complex'
```

Definition. Evaluate `sum (scale*z)**(order*n+residue)/(order*n+residue)!`.

Contract (D, C, H, R, X). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (E, P, B, K). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_cyclic_reciprocal.py`, `tests/test_analytic_appell_zeros.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

C.1G · `transfer_tangent`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.transfer_tangent`. Reflected implementation `komorebi_math.analytic.reciprocal.transfer_tangent`. The same runtime object is also available through `komorebi_math.analytic.transfer_tangent`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-ANALYTIC`.

Manifest signature (`s`).

```
(order: 'int', z: 'complex') -> 'complex'
```

Definition. Evaluate `-D_order'(z)/D_order(z)`.

Contract (`D, C, H, R, X`). Orders and truncation degrees are nonnegative. Denominators and section parameters must avoid their declared singular cases. Numerical zero and tangent diagnostics require finite search windows and a positive tolerance.

Guarantees (`E, P, B, K`). Coefficient transforms are exact when their inputs are exact. Numerical root and tangent records certify only the finite interval, truncation, and tolerance that were actually evaluated. They do not establish an unrestricted analytic theorem.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_analytic_cyclic_reciprocal.py`, `tests/test_analytic_appell_zeros.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 27.

Quantum and dynamical systems (19 cards).

C.1G · `BayesianUpdate`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.BayesianUpdate`. Reflected implementation `komorebi_math.dynamics.bayes.BayesianUpdate`. The same runtime object is also available through `komorebi_math.dynamics.BayesianUpdate`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DYNAMICS`.

Manifest signature (`s`).

```
(prior: 'Any', likelihood: 'Any') -> 'None'
```

Definition. A normalized finite Bayesian update.

Contract (`D, C, H, R, X`). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors. Public fields are `prior`, `likelihood`. Principal public operations are `evidence`, `posterior`, `perturbation_bound`.

Guarantees (`E, P, B, K`). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_feshbach.py`, `tests/test_dynamics_fractional_green_feynman_survival.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · `CircuitPacketExpansion`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.CircuitPacketExpansion`. Reflected implementation `komorebi_math.quantum.circuits.CircuitPacketExpansion`. The same runtime object is also available through `komorebi_math.quantum.CircuitPacketExpansion`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(gates: 'Iterable[Any]', packet_systems: 'Iterable[PacketSystem]', *, tolerance: 'float' = 1e-10, max_paths: 'int'
    ↪  = 1000000) -> 'None'
```

Definition. Insert packet resolutions between every gate of a finite circuit.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Principal public operations are `dimension`, `unitary`, `path_blocks`, `block`, `reconstruction_certificate`, `interference`, `block_unitarity_certificate`.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_symmetry_circuits.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · `EuclideanTransfer`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.EuclideanTransfer`. Reflected implementation `komorebi_math.quantum.euclidean.EuclideanTransfer`. The same runtime object is also available through `komorebi_math.quantum.EuclideanTransfer`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(hamiltonian: 'Any', lattice_spacing: 'float', *, ground_energy: 'float | None' = None, tolerance: 'float' = 1e-10)
    ↪  -> 'None'
```

Definition. A positive Euclidean transfer operator generated by a Hermitian Hamiltonian.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Public fields are `hamiltonian`, `lattice_spacing`, `ground_energy`, `tolerance`. Principal public operations are `shifted_hamiltonian`, `operator`, `reflection_matrix`, `reflection_certificate`, `from_transfer`.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · FeshbachReduction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FeshbachReduction`. Reflected implementation `komorebi_math.dynamics.feshbach.FeshbachReduction`. The same runtime object is also available through `komorebi_math.dynamics.FeshbachReduction`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DYNAMICS`.

Manifest signature (s).

```
(matrix: 'Any', retained: 'Iterable[int]') -> 'None'
```

Definition. Retained and hidden block reduction of a finite matrix.

Contract (D, C, H, R, X). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors. Public fields are `matrix`, `retained`, `hidden`. Principal public operations are `retained_block`, `hidden_block`, `retained_to_hidden`, `hidden_to_retained`, `a_pq`, `a_qp`, `self_energy`, `effective_operator`, `effective_resolvent`, `direct_projected_resolvent`, `resolvent_certificate`, `memory_kernel`, `memory_kernel_at`, `hidden_source`, `closure_moments`, `local_closure_certificate`.

Guarantees (E, P, B, K). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_dynamics_feshbach.py`, `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_fractional_green_feynman_survival.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · LindbladGenerator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.LindbladGenerator`. Reflected implementation `komorebi_math.quantum.lindblad.LindbladGenerator`. The same runtime object is also available through `komorebi_math.quantum.LindbladGenerator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(hamiltonian: 'Any', jumps: 'Iterable[Any]', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. A finite Gorini Kossakowski Sudarshan Lindblad generator.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Principal public operations are `apply`, `superoperator`, `evolve`, `trace_preservation_certificate`, `coherence_preservation_certificate`.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_channels_qec.py`, `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · MarkovLumping

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MarkovLumping`. Reflected implementation `komorebi_math.dynamics.markov.MarkovLumping`. The same runtime object is also available through `komorebi_math.dynamics.MarkovLumping`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DYNAMICS`.

Manifest signature (s).

```
(operator: 'Any | FiniteMarkovChain | ContinuousTimeMarkovChain', partition: 'Sequence[int] |
    ↪ Iterable[Iterable[int]]', *, kind: 'MarkovKind | None' = None) -> 'None'
```

Definition. A finite state aggregation for a column convention Markov operator.

Contract (D, C, H, R, X). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors. Public fields are `chain`, `aggregation_map`. Principal public operations are `partition`, `blocks`, `aggregation`, `obstruction`, `is_exact`, `approximate_coarse_operator`, `exact_coarse_operator`, `coarse_operator`, `coarse_generator`, `coarse_transition`, `coarse_chain`, `certificate`, `aggregate`, `evolution_defect`, `semigroup_defect`, `error_bound`.

Guarantees (E, P, B, K). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_feshbach.py`, `tests/test_dynamics_fractional_green_feynman_survival.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · MatrixSemigroup

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MatrixSemigroup`. Reflected implementation `komorebi_math.dynamics.semigroups.MatrixSemigroup`. The same runtime object is also available through `komorebi_math.dynamics.MatrixSemigroup`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DYNAMICS`.

Manifest signature (s).

```
(generator: 'np.ndarray') -> None
```

Definition. The finite semigroup generated by one square matrix.

Contract (D, C, H, R, X). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors. Public fields are `generator`. Principal public operations are `dimension`, `at`, `operator`, `apply`, `resolvent`, `semigroup_certificate`.

Guarantees (E, P, B, K). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_block4_hardening.py`, `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_feshbach.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · MemoryKernel

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MemoryKernel`. Reflected implementation `komorebi_math.dynamics.memory.MemoryKernel`. The same runtime object is also available through `komorebi_math.dynamics.MemoryKernel`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DYNAMICS`.

Manifest signature (s).

```
(output: 'Any', hidden: 'Any', input: 'Any') -> 'None'
```

Definition. A matrix kernel `B exp(tD) C` with rational Laplace transform.

Contract (D, C, H, R, X). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors. Public fields are `output`, `hidden`, `input`. Principal public operations are `retained_dimension`, `hidden_dimension`, `at`, `evaluate`, `laplace`, `finite_laplace`, `certificate`.

Guarantees (E, P, B, K). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_dynamics_feshbach.py`, `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_fractional_green_feynman_survival.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · PhaseTypeSurvival

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PhaseTypeSurvival`. Reflected implementation `komorebi_math.dynamics.survival.PhaseTypeSurvival`. The same runtime object is also available through `komorebi_math.dynamics.PhaseTypeSurvival`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DYNAMICS`.

Manifest signature (s).

```
(subgenerator: 'Any', initial: 'Any', *, cause_rates: 'Any | None' = None, tolerance: 'float' = 1e-12, validate:
    ↪ 'bool' = True) -> 'None'
```

Definition. A finite transient subgenerator acting on column probabilities.

Contract (D, C, H, R, X). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors. Public fields are `subgenerator`, `initial`, `cause_rates`, `tolerance`. Principal public operations are `states`, `absorption_rates`, `certificate`, `transient_probability`, `survival`, `density`, `hazard`, `laplace_transform`, `moment`, `cause_density`, `residual_initial`, `residual_model`, `identities_certificate`.

Guarantees (E, P, B, K). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_block4_hardening.py`, `tests/test_dynamics_fractional_green_feynman_survival.py`, `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_bayes_martingales.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace

checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · `QuantumChannel`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.QuantumChannel`. Reflected implementation `komorebi_math.quantum.channels.QuantumChannel`. The same runtime object is also available through `komorebi_math.quantum.QuantumChannel`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (`s`).

```
(kraus: 'Iterable[Any]', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. A finite completely positive map represented by Kraus operators.

Contract (`D, C, H, R, X`). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Principal public operations are `identity`, `apply`, `apply_density`, `adjoint`, `is_trace_preserving`, `is_unital`, `certificate`, `superoperator`, `choi_matrix`, `compose`, `tensor`, `packet_blocks`, `covariance_certificate`.

Guarantees (`E, P, B, K`). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_channels_qec.py`, `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · `QuantumCode`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.QuantumCode`. Reflected implementation `komorebi_math.quantum.error_correction.QuantumCode`. The same runtime object is also available through `komorebi_math.quantum.QuantumCode`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (`s`).

```
(projector: 'Any', errors: 'Iterable[Any]', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. A finite code projector with a declared family of error operators.

Contract (`D, C, H, R, X`). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Principal public operations are `knill_laflamme_report`, `recovery_channel`, `recovered_channel_certificate`, `encode_density`.

Guarantees (`E, P, B, K`). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_channels_qec.py`, `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · QuantumFeshbachReduction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.QuantumFeshbachReduction`. Reflected implementation `komorebi_math.quantum.effective.QuantumFeshbachReduction`. The same runtime object is also available through `komorebi_math.quantum.QuantumFeshbachReduction`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(hamiltonian: 'Any', retained: 'Iterable[int]', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. Hermitian specialization of the finite Schur Feshbach reduction.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Principal public operations are `self_energy`, `effective_hamiltonian`, `projected_resolvent`, `resolvent_certificate`, `upper_half_plane_sign_certificate`, `memory_kernel`, `bare_closure_certificate`.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · QuantumSeedSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.QuantumSeedSystem`. Reflected implementation `komorebi_math.quantum.seeds.QuantumSeedSystem`. The same runtime object is also available through `komorebi_math.quantum.QuantumSeedSystem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(observables: 'Mapping[str, Any] | Sequence[Any]', seeds: 'Sequence[Any]', *, tolerance: 'float' = 1e-10) -> 'None'
```

Definition. A finite observable algebra acting on one or more quantum seeds.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions. Principal public operations are `dimension`, `orbit_basis`, `orbit_dimension`, `is_generating`, `certificate`.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_symmetry_circuits.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · constraint_closure

Identity (q, a, t, k). Public research-manifest route `komorebi_math.constraint_closure`. Reflected implementation `komorebi_math.quantum.constraints.constraint_closure`. The same runtime object is also available through `komorebi_math.quantum.constraint_closure`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(constraints: 'Iterable[Any]', *, tolerance: 'float' = 1e-10) -> 'ConstraintClosureReport'
```

Definition. Project every commutator onto the declared complex linear constraint span.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · cyclic_symmetry_projectors

Identity (q, a, t, k). Public research-manifest route `komorebi_math.cyclic_symmetry_projectors`. Reflected implementation `komorebi_math.quantum.symmetry.cyclic_symmetry_projectors`. The same runtime object is also available through `komorebi_math.quantum.cyclic_symmetry_projectors`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(symmetry: 'Any', order: 'int', *, tolerance: 'float' = 1e-10) -> 'PacketSystem'
```

Definition. Return the complete packet system of a finite cyclic unitary symmetry.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`, `tests/test_quantum_transport_effective_spectral.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · fixed_packet_leakage

Identity (q, a, t, k). Public research-manifest route `komorebi_math.fixed_packet_leakage`. Reflected implementation `komorebi_math.quantum.leakage.fixed_packet_leakage`. The same runtime object is also available through `komorebi_math.quantum.fixed_packet_leakage`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(hamiltonian: 'Any', projector: 'Any', time: 'float', *, tolerance: 'float' = 1e-10) -> 'LeakageResult'
```

Definition. Evaluate and certify `||(I-P)e^{-itH}P|| <= |t| ||(I-P)HP||`.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · fractional_power

Identity (q, a, t, k). Public research-manifest route `komorebi_math.fractional_power`. Reflected implementation `komorebi_math.dynamics.fractional.fractional_power`. The same runtime object is also available through `komorebi_math.dynamics.fractional_power`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-DYNAMICS`.

Manifest signature (s).

```
(matrix: 'Any', exponent: 'float', *, tolerance: 'float' = 1e-12) -> 'np.ndarray'
```

Definition. Return the positive spectral power of a finite Hermitian matrix.

Contract (D, C, H, R, X). State spaces and operators are finite dimensional. Probabilities and likelihoods are nonnegative, stochastic data are normalized, and block reductions require compatible partitions. Fractional and memory operators retain the branch and regularity assumptions stated by their constructors.

Guarantees (E, P, B, K). Results describe the supplied finite model, partition, prior, kernel, or generator. Exact combinatorial parts remain exact and numerical reductions report finite residuals. No asymptotic or continuum claim is inferred beyond the represented system.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_dynamics_fractional_green_feynman_survival.py`, `tests/test_dynamics_semigroups_markov.py`, `tests/test_dynamics_bayes_martingales.py`, `tests/test_dynamics_feshbach.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 44 through 48.

C.1G · periodic_laplacian

Identity (q, a, t, k). Public research-manifest route `komorebi_math.periodic_laplacian`. Reflected implementation `komorebi_math.quantum.spectral.periodic_laplacian`. The same runtime object is also available through `komorebi_math.quantum.periodic_laplacian`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(shape: 'Sequence[int]', *, spacing: 'float | None' = None) -> 'np.ndarray'
```

Definition. Construct the finite nearest neighbor periodic lattice Laplacian.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

C.1G · spectral_dimension

Identity (q, a, t, k). Public research-manifest route `komorebi_math.spectral_dimension`. Reflected implementation `komorebi_math.quantum.spectral.spectral_dimension`. The same runtime object is also available through `komorebi_math.quantum.spectral_dimension`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-QUANTUM`.

Manifest signature (s).

```
(operator: 'Any', time: 'float') -> 'float'
```

Definition. Return `2*t*Tr(L exp(-tL))/Tr(exp(-tL))`.

Contract (D, C, H, R, X). Matrices and packet systems are finite dimensional and shape compatible. Tolerances and path budgets must be positive. Channel, code, circuit, and spectral contracts reject incompatible dimensions, nonfinite entries, and failed normalization conditions.

Guarantees (E, P, B, K). Results concern the supplied finite matrices and tolerance. Exact symbolic components remain exact, while floating-point certificates report measured residuals. These contracts do not claim hardware execution or a physical realization.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_quantum_transport_effective_spectral.py`, `tests/test_quantum_channels_qec.py`, `tests/test_quantum_symmetry_circuits.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 53 through 55.

Deformation and Langlands systems (34 cards).

C.1G · AlternatingForm

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AlternatingForm`. Reflected implementation `komorebi_math.langlands.local.symplectic.AlternatingForm`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(matrix: 'Any', prime: 'int') -> None
```

Definition. A finite alternating bilinear form over a prime field.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `matrix`, `prime`. Principal public operations are `dimension`, `rank`, `radical_dimension`, `nondegenerate`, `radical_basis`, `evaluate`, `certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · AutomorphicCompletionReport

Identity (q, a, t, k). Public research-manifest route `komorebi_math.AutomorphicCompletionReport`. Reflected implementation `komorebi_math.langlands.completion.gates.AutomorphicCompletionReport`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(gates: 'Mapping[CompletionGate | str, GateStatus]') -> None
```

Definition. A five-gate conditional automorphic completion report.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `gates`. Principal public operations are `complete`, `unmet_gates`, `external_gates`, `result`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · AutomorphicInductionPlan

Identity (q, a, t, k). Public research-manifest route komorebi_math.AutomorphicInductionPlan. Reflected implementation komorebi_math.langlands.finite_image.plans.AutomorphicInductionPlan. The root export resolves directly to this nested implementation owner. The umbrella komorebi_math.langlands package does not publish a second alias. The root route is governed by [RESEARCH] policy pre-beta-additive. It does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1G-LANGLANDS.

Manifest signature (s).

```
(representation: 'InducedRepresentation[Element]', base_field: 'str', inducing_field: 'str', inducing_character:
    ↪ 'str', cyclic_tower: 'tuple[str, ...]' = ()) -> None
```

Definition. A conditional symbolic plan attached to one induced character parameter.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are representation, base_field, inducing_field, inducing_character, cyclic_tower. Principal public operations are operations.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include tests/test_langlands_finite_image.py, tests/test_langlands_local_heisenberg_symplectic.py, tests/test_langlands_local_fields_tame_gauss.py, tests/test_langlands_ramification_global_completion.py. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · CliffordStep

Identity (q, a, t, k). Public research-manifest route komorebi_math.CliffordStep. Reflected implementation komorebi_math.langlands.finite_image.clifford.CliffordStep. The root export resolves directly to this nested implementation owner. The umbrella komorebi_math.langlands package does not publish a second alias. The root route is governed by [RESEARCH] policy pre-beta-additive. It does not enlarge the frozen stable compatibility promise. Manifest kind class. Profile C1G-LANGLANDS.

Manifest signature (s).

```
(parent_order: 'int', child_order: 'int', parent_degree: 'int', child_degree: 'int', mode: 'CliffordMode | str',
    ↪ attached_descent: 'bool' = False, label: 'str' = '') -> None
```

Definition. One validated prime-cyclic step in a declared Clifford tower.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are parent_order, child_order, parent_degree, child_degree, mode, attached_descent, label. Principal public operations are quotient_prime, nonabelian_extension_gate.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include tests/test_langlands_finite_image.py, tests/test_langlands_local_heisenberg_symplectic.py, tests/test_langlands_local_fields_tame_gauss.py, tests/test_langlands_ramification_global_completion.py. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The

source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · `CliffordTower`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.CliffordTower`. Reflected implementation `komorebi_math.langlands.finite_image.clifford.CliffordTower`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (`s`).

```
(steps: 'Iterable[CliffordStep]') -> 'None'
```

Definition. A finite prime-cyclic Clifford tower supplied with dimension data.

Contract (`D, C, H, R, X`). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `word`, `depth`, `report`, `automorphic_plan`.

Guarantees (`E, P, B, K`). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · `CompatiblePropagationReport`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.CompatiblePropagationReport`. Reflected implementation `komorebi_math.langlands.completion.gates.CompatiblePropagationReport`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (`s`).

```
(common_spine: 'bool', semisimple: 'bool', one_member_automorphic: 'bool', local_global_compatibility: 'bool') ->
    ↪ None
```

Definition. One-member propagation through an already supplied compatible system.

Contract (`D, C, H, R, X`). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `common_spine`, `semisimple`, `one_member_automorphic`, `local_global_compatibility`. Principal public operations are `result`.

Guarantees (`E, P, B, K`). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The

source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · `CompletionGate`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.CompletionGate`. Reflected implementation `komorebi_math.langlands.completion.gates.CompletionGate`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (`s`).

```
(*values)
```

Definition. The five formal gates in pointwise automorphic completion.

Contract (`D, C, H, R, X`). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate.

Guarantees (`E, P, B, K`). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · `FiniteCochainComplex`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.FiniteCochainComplex`. Reflected implementation `komorebi_math.deformation.complexes.FiniteCochainComplex`. The same runtime object is also available through `komorebi_math.deformation.FiniteCochainComplex`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DEFORMATION`.

Manifest signature (`s`).

```
(dimensions: 'Mapping[int, int]', differentials: 'Mapping[int, Any]', *, prime: 'int') -> 'None'
```

Definition. A bounded finite cochain complex over a prime field.

Contract (`D, C, H, R, X`). Complexes, modules, forests, and Frobenius data are finite. Prime-field operations require a valid prime, differential matrices must match the declared dimensions, and cochain data must satisfy the finite compatibility checks enforced by the implementation. Principal public operations are `differential`, `cohomology`, `certificate`, `packet_cohomology`.

Guarantees (`E, P, B, K`). Cohomology, support, visibility, and companion calculations are exact over the declared finite field or finite presentation. The records do not by themselves prove an unrestricted deformation or lifting theorem.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_deformation_complex_support_companions.py`, `tests/test_deformation_forests_visibility_counting.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 56.

C.1G · FiniteField

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteField`. Reflected implementation `komorebi_math.langlands.local.finite_fields.FiniteField`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(prime: 'int', degree: 'int' = 1, modulus: 'tuple[int, ...] | None' = None) -> None
```

Definition. The field `F_(p^degree)` in one explicit polynomial basis.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `prime`, `degree`, `modulus`. Principal public operations are `order`, `normalize`, `encode`, `decode`, `element`, `coerce`, `add`, `subtract`, `negate`, `multiply`, `power`, `inverse`, `elements`, `trace`, `norm`, `discrete_log`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · FiniteGroup

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteGroup`. Reflected implementation `komorebi_math.langlands.finite_image.groups.FiniteGroup`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(elements: 'Iterable[Element]', multiply: 'Callable[[Element, Element], Element]', identity: 'Element', *, name:
    ↪ 'str' = 'G', validate: 'bool' = True, associativity_limit: 'int' = 128) -> 'None'
```

Definition. A finite group given by an explicit element set and multiplication law.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `order`, `inverse`, `power`, `generated_subgroup`, `subgroup`, `left_coset_representatives`, `double_coset_representatives`, `certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · FiniteHeckePackets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteHeckePackets`. Reflected implementation `komorebi_math.langlands.global_.hecke.FiniteHeckePackets`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(projectors: 'Mapping[str, Any]', *, commuting_operators: 'Iterable[Any]' = (), tolerance: 'float' = 1e-10) ->
    ↪ 'None'
```

Definition. A validated finite family of central idempotents on one carrier.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `packets`, `occupied`, `certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · FiniteLiftForest

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FiniteLiftForest`. Reflected implementation `komorebi_math.deformation.forests.FiniteLiftForest`. The same runtime object is also available through `komorebi_math.deformation.FiniteLiftForest`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DEFORMATION`.

Manifest signature (s).

```
(levels: 'Mapping[int, Iterable[Node]]', reductions: 'Mapping[int, Callable[[Node], Node] | Mapping[Node, Node]]')
    ↪ -> 'None'
```

Definition. A finite inverse system of lift levels with explicit reduction maps.

Contract (D, C, H, R, X). Complexes, modules, forests, and Frobenius data are finite. Prime-field operations require a valid prime, differential matrices must match the declared dimensions, and cochain data must satisfy the finite compatibility checks enforced by the implementation. Principal public operations are `max_depth`, `level`, `reduce`, `children`, `image`, `stable_core`, `branches`, `report`.

Guarantees (E, P, B, K). Cohomology, support, visibility, and companion calculations are exact over the declared finite field or finite presentation. The records do not by themselves prove an unrestricted deformation or lifting theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_deformation_forests_visibility_counting.py`, `tests/test_deformation_complex_support_companions.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 56.

C.1G · FrobeniusOrbit

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FrobeniusOrbit`. Reflected implementation `komorebi_math.langlands.local.tame.FrobeniusOrbit`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(q: 'int', degree: 'int', exponent: 'int') -> None
```

Definition. A tame character orbit under multiplication by the residue cardinality.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `q`, `degree`, `exponent`. Principal public operations are `modulus`, `elements`, `orbit_length`, `regular`, `dual_exponent`, `self_dual`, `certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · FrobeniusSpine

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FrobeniusSpine`. Reflected implementation `komorebi_math.deformation.companions.FrobeniusSpine`. The same runtime object is also available through `komorebi_math.deformation.FrobeniusSpine`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DEFORMATION`.

Manifest signature (s).

```
(polynomials: 'Mapping[Hashable, tuple[Any, ...]]', local_labels: 'Mapping[Hashable, Any] | None' = None) -> None
```

Definition. One finite algebraic spine of monic Frobenius polynomials.

Contract (D, C, H, R, X). Complexes, modules, forests, and Frobenius data are finite. Prime-field operations require a valid prime, differential matrices must match the declared dimensions, and cochain data must satisfy the finite compatibility checks enforced by the implementation. Public fields are `polynomials`, `local_labels`. Principal public operations are `rank`, `agrees`.

Guarantees (E, P, B, K). Cohomology, support, visibility, and companion calculations are exact over the declared finite field or finite presentation. The records do not by themselves prove an unrestricted deformation or lifting theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_deformation_complex_support_companions.py`, `tests/test_deformation_forests_visibility_counting.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 56.

C.1G · GateStatus

Identity (q, a, t, k). Public research-manifest route `komorebi_math.GateStatus`. Reflected implementation `komorebi_math.langlands.completion.gates.GateStatus`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(satisfied: 'bool', detail: 'str', external: 'bool' = True) -> None
```

Definition. One gate value with a human-readable explanation.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `satisfied`, `detail`, `external`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · HeisenbergModel

Identity (q, a, t, k). Public research-manifest route `komorebi_math.HeisenbergModel`. Reflected implementation `komorebi_math.langlands.local.heisenberg.HeisenbergModel`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(prime: 'int', rank: 'int', *, max_dimension: 'int' = 4096) -> 'None'
```

Definition. The finite Schrödinger representation over `F_p^rank`.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `element`, `multiply`, `inverse`, `translation_matrix`, `modulation_matrix`, `matrix`, `group_law_certificate`, `trace`, `trace_support_certificate`, `translation_selector`, `selector_certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · `InducedRepresentation`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.InducedRepresentation`. Reflected implementation `komorebi_math.langlands.finite_image.characters.InducedRepresentation`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (`s`).

```
(group: 'FiniteGroup[Element]', character: 'LinearCharacter[Element]') -> 'None'
```

Definition. The explicit monomial representation induced from a linear character.

Contract (`D, C, H, R, X`). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `basis_action`, `matrix`, `trace`, `certificate`.

Guarantees (`E, P, B, K`). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · `LinearCharacter`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.LinearCharacter`. Reflected implementation `komorebi_math.langlands.finite_image.characters.LinearCharacter`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (`s`).

```
(subgroup: 'FiniteSubgroup[Element]', values: 'Mapping[Element, complex]', tolerance: 'float' = 1e-10) -> None
```

Definition. A one dimensional complex character of an explicit finite subgroup.

Contract (`D, C, H, R, X`). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `subgroup`, `values`, `tolerance`. Principal public operations are `conjugate`.

Guarantees (`E, P, B, K`). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · MonomialAction

Identity (q, a, t, k). Public research-manifest route `komorebi_math.MonomialAction`. Reflected implementation `komorebi_math.langlands.finite_image.orbits.MonomialAction`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(representation: 'InducedRepresentation[Element]') -> 'None'
```

Definition. A finite monomial action described by permutations and basis scalars.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `symmetric_power_packets`, `exterior_power_packets`, `tensor_packets`, `packet_certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · PatchingSupportReport

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PatchingSupportReport`. Reflected implementation `komorebi_math.langlands.global_.patching.PatchingSupportReport`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(patched_object_exists: 'bool', patched_full_support: 'bool', finite_level_descent: 'bool',
    ↪ comparison_preserves_support: 'bool', characteristic_zero_fiber_nonzero: 'bool', derived: 'bool' = False) ->
    ↪ None
```

Definition. A conditional support report for one patched module or complex.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `patched_object_exists`, `patched_full_support`, `finite_level_descent`, `comparison_preserves_support`, `characteristic_zero_fiber_nonzero`, `derived`. Principal public operations are `complete`, `unmet`, `certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The

source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · PresentedModule

Identity (q, a, t, k). Public research-manifest route `komorebi_math.PresentedModule`. Reflected implementation `komorebi_math.deformation.support.PresentedModule`. The same runtime object is also available through `komorebi_math.deformation.PresentedModule`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DEFORMATION`.

Manifest signature (s).

```
(presentation: 'Any', *, variables: 'Iterable[Any]' = ()) -> 'None'
```

Definition. A finite module presented by a matrix of relations.

Contract (D, C, H, R, X). Complexes, modules, forests, and Frobenius data are finite. Prime-field operations require a valid prime, differential matrices must match the declared dimensions, and cochain data must satisfy the finite compatibility checks enforced by the implementation. Principal public operations are `fitting_generators`, `evaluate`, `fiber`, `finite_support`.

Guarantees (E, P, B, K). Cohomology, support, visibility, and companion calculations are exact over the declared finite field or finite presentation. The records do not by themselves prove an unrestricted deformation or lifting theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_deformation_complex_support_companions.py`, `tests/test_deformation_forests_visibility_counting.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 56.

C.1G · ProjectiveIntertwinerEnvelope

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ProjectiveIntertwinerEnvelope`. Reflected implementation `komorebi_math.langlands.local.envelopes.ProjectiveIntertwinerEnvelope`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(*, prime: 'int', labels: 'Iterable[Iterable[int]]', operators: 'Iterable[Any]', tolerance: 'float' = 1e-08) ->
    ↪ 'None'
```

Definition. Recover a finite commutator pairing from projective intertwiners.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `recover`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · ProjectiveMultiplicityPacket

Identity (q, a, t, k). Public research-manifest route `komorebi_math.ProjectiveMultiplicityPacket`. Reflected implementation `komorebi_math.langlands.ramification.towers.ProjectiveMultiplicityPacket`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(prime: 'int', quotient_rank: 'int', form: 'AlternatingForm', phase_label: 'str | None' = None,
    ↪ quadratic_refinement: 'QuadraticRefinement | None' = None) -> None
```

Definition. A finite projective multiplicity packet at one ramification stage.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `prime`, `quotient_rank`, `form`, `phase_label`, `quadratic_refinement`. Principal public operations are `radical_dimension`, `symplectic_rank`, `heisenberg_dimension`, `phase_diagnostic`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · QuadraticRefinement

Identity (q, a, t, k). Public research-manifest route `komorebi_math.QuadraticRefinement`. Reflected implementation `komorebi_math.langlands.local.symplectic.QuadraticRefinement`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(form: 'AlternatingForm', linear: 'tuple[int, ...]' = (), max_dimension: 'int' = 20) -> None
```

Definition. A dyadic quadratic refinement of a finite alternating form.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `form`, `linear`, `max_dimension`. Principal public operations are `evaluate`, `polar_certificate`, `gauss_sum`, `arf_invariant`, `normalized_gauss_sign`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · RamificationCliffordTower

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RamificationCliffordTower`. Reflected implementation `komorebi_math.langlands.ramification.towers.RamificationCliffordTower`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(stages: 'Iterable[RamificationStage]') -> 'None'
```

Definition. A finite ramification-adapted chain of Clifford packet stages.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Principal public operations are `report`, `tensor_packet`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · RamificationStage

Identity (q, a, t, k). Public research-manifest route `komorebi_math.RamificationStage`. Reflected implementation `komorebi_math.langlands.ramification.towers.RamificationStage`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(break_number: 'int', parent_order: 'int', child_order: 'int', orbit_size: 'int', multiplicity_dimension: 'int',
    ↪ packet: 'ProjectiveMultiplicityPacket | None' = None, label: 'str' = '') -> None
```

Definition. One finite stage in a declared ramification-adapted tower.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `break_number`, `parent_order`, `child_order`, `orbit_size`, `multiplicity_dimension`, `packet`, `label`. Principal public operations are `reconstructed_dimension`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · SupportComparison

Identity (q, a, t, k). Public research-manifest route `komorebi_math.SupportComparison`. Reflected implementation `komorebi_math.langlands.global_.hecke.SupportComparison`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(source_components: 'frozenset[str]', target_components: 'frozenset[str]', image_components: 'frozenset[str]',
   ↪  certificate: 'Certificate') -> None
```

Definition. A support-preserving or support-losing comparison diagnostic.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `source_components`, `target_components`, `image_components`, `certificate`. Principal public operations are `construct`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · TameWeilPacket

Identity (q, a, t, k). Public research-manifest route `komorebi_math.TameWeilPacket`. Reflected implementation `komorebi_math.langlands.local.tame.TameWeilPacket`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(orbit: 'FrobeniusOrbit', frobenius_scalar: 'complex' = 1.0) -> None
```

Definition. A finite matrix model of one regular tame Weil atom.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate. Public fields are `orbit`, `frobenius_scalar`. Principal public operations are `dimension`, `inertia_matrix`, `frobenius_matrix`, `determinant_orientation`, `relation_certificate`.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · VisibilityTree

Identity (q, a, t, k). Public research-manifest route `komorebi_math.VisibilityTree`. Reflected implementation `komorebi_math.deformation.visibility.VisibilityTree`. The same runtime object is also available through `komorebi_math.deformation.VisibilityTree`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-DEFORMATION`.

Manifest signature (s).

```
(values: 'Iterable[Fraction | int]', *, prime: 'int') -> 'None'
```

Definition. Nested visibility partitions of finitely many exact local coordinates.

Contract (D, C, H, R, X). Complexes, modules, forests, and Frobenius data are finite. Prime-field operations require a valid prime, differential matrices must match the declared dimensions, and cochain data must satisfy the finite compatibility checks enforced by the implementation. Principal public operations are `separation_depth`, `pairwise_depths`, `partition`, `refinement_chain`, `ultrametric_certificate`.

Guarantees (E, P, B, K). Cohomology, support, visibility, and companion calculations are exact over the declared finite field or finite presentation. The records do not by themselves prove an unrestricted deformation or lifting theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_deformation_forests_visibility_counting.py`, `tests/test_deformation_complex_support_companions.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 56.

C.1G · cyclic_group

Identity (q, a, t, k). Public research-manifest route `komorebi_math.cyclic_group`. Reflected implementation `komorebi_math.langlands.finite_image.groups.cyclic_group`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(order: 'int') -> 'FiniteGroup[int]'
```

Definition. Return the additive cyclic group of the declared order.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · dyadic_sign_diagnostic

Identity (q, a, t, k). Public research-manifest route `komorebi_math.dyadic_sign_diagnostic`. Reflected implementation `komorebi_math.langlands.global_.dyadic.dyadic_sign_diagnostic`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
() -> 'DyadicSignDiagnostic'
```

Definition. Return the exact integral and residual sign packet diagnostic.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_ramification_global_completion.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · finite_frobenius_separator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.finite_frobenius_separator`. Reflected implementation `komorebi_math.deformation.companions.finite_frobenius_separator`. The same runtime object is also available through `komorebi_math.deformation.finite_frobenius_separator`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-DEFORMATION`.

Manifest signature (s).

```
(traces: 'Mapping[Hashable, Sequence[Any]]', *, constituent_count: 'int | None' = None) ->
    ↪ 'FrobeniusSeparationResult'
```

Definition. Select finitely many supplied places that separate trace columns.

Contract (D, C, H, R, X). Complexes, modules, forests, and Frobenius data are finite. Prime-field operations require a valid prime, differential matrices must match the declared dimensions, and cochain data must satisfy the finite compatibility checks enforced by the implementation.

Guarantees (E, P, B, K). Cohomology, support, visibility, and companion calculations are exact over the declared finite field or finite presentation. The records do not by themselves prove an unrestricted deformation or lifting theorem.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_deformation_complex_support_companions.py`, `tests/test_deformation_forests_visibility_counting.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapter 56.

C.1G · gauss_sum

Identity (q, a, t, k). Public research-manifest route `komorebi_math.gauss_sum`. Reflected implementation `komorebi_math.langlands.local.gauss.gauss_sum`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(field: 'FiniteField', exponent: 'int', *, additive_frequency: 'int' = 1, tolerance: 'float' = 1e-09) ->
   ↪ 'GaussSumResult'
```

Definition. Compute one finite multiplicative and additive Gauss sum.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

C.1G · mackey_tensor_packets

Identity (q, a, t, k). Public research-manifest route `komorebi_math.mackey_tensor_packets`. Reflected implementation `komorebi_math.langlands.finite_image.mackey.mackey_tensor_packets`. The root export resolves directly to this nested implementation owner. The umbrella `komorebi_math.langlands` package does not publish a second alias. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-LANGLANDS`.

Manifest signature (s).

```
(group: 'FiniteGroup[Element]', left: 'LinearCharacter[Element]', right: 'LinearCharacter[Element]') ->
   ↪ 'MackeyDecomposition[Element]'
```

Definition. Return the Mackey packets for two character-induced representations.

Contract (D, C, H, R, X). Fields, groups, characters, packets, and towers are finite explicit objects. Representation dimensions, actions, cocycles, and local parameters must be compatible. Completion reports require an explicit status for every declared gate.

Guarantees (E, P, B, K). Finite-field, finite-group, local-packet, ramification, and gate calculations are explicit and reproducible. Global completion objects remain conditional on their recorded gates. This API does not claim a proof of the general Langlands correspondence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_langlands_finite_image.py`, `tests/test_langlands_local_heisenberg_symplectic.py`, `tests/test_langlands_local_fields_tame_gauss.py`, `tests/test_langlands_ramification_global_completion.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 57 and 58.

Registry, unified workflow, and root data (9 cards).

C.1G · DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE

Identity (q, a, t, k). Public research-manifest route `komorebi_math.DEFAULT_BEHAVIORAL_GOLDEN_FIXTURE`. Reflected implementation `pathlib.Path`. This is a root data export rather than a callable facade. The public name maps to implementation object `Path`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `data`. Profile `C1G-ROOT-DATA`.

Manifest signature (s).

```
null
```

Definition. Default package path for the committed behavioral-golden fixture.

Contract (D, C, H, R, X). The exported value is a read-only package-data location. It may be inspected or passed to the matching loader, but it does not promise that the installation directory is writable.

Guarantees (E, P, B, K). The path resolves relative to the installed package and identifies the committed default resource for that installation. The file contents remain governed by the corresponding loader and compatibility contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_block11_golden_profiling_beta.py`, `tests/test_block15_stable_api.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 6 and 61.

C.1G · DEFAULT_BETA_API_MANIFEST

Identity (q, a, t, k). Public research-manifest route `komorebi_math.DEFAULT_BETA_API_MANIFEST`. Reflected implementation `pathlib.Path`. This is a root data export rather than a callable facade. The public name maps to implementation object `Path`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `data`. Profile `C1G-ROOT-DATA`.

Manifest signature (s).

```
null
```

Definition. Default package path for the frozen beta API manifest.

Contract (D, C, H, R, X). The exported value is a read-only package-data location. It may be inspected or passed to the matching loader, but it does not promise that the installation directory is writable.

Guarantees (E, P, B, K). The path resolves relative to the installed package and identifies the committed default resource for that installation. The file contents remain governed by the corresponding loader and compatibility contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_block11_golden_profiling_beta.py`, `tests/test_block15_stable_api.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 6 and 61.

C.1G · FeatureSpec

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FeatureSpec`. Reflected implementation `komorebi_math.registry.FeatureSpec`. The same runtime object is also available through `komorebi_math.registry.FeatureSpec`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REGISTRY`.

Manifest signature (s).

```
(key: 'str', module: 'str', title: 'str', status: 'FeatureStatus', summary: 'str', papers: 'tuple[str, ...]' = (),
   ↪ dependencies: 'tuple[str, ...]' = (), public_objects: 'tuple[str, ...]' = ()) -> None
```

Definition. Immutable metadata describing one registered package feature.

Contract (D, C, H, R, X). Feature names and metadata are explicit, finite, and validated before registration or lookup. Registry queries do not infer support that is absent from the committed feature record. Public fields are `key`, `module`, `title`, `status`, `summary`, `papers`, `dependencies`, `public_objects`. Principal public operations are `to_dict`.

Guarantees (E, P, B, K). Registry results reproduce the committed metadata and support status. They are descriptive records, not runtime capability probes or publication evidence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused test module is `tests/test_certificates_registry.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 6 and 62.

C.1G · `FeatureStatus`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.FeatureStatus`. Reflected implementation `komorebi_math.registry.FeatureStatus`. The same runtime object is also available through `komorebi_math.registry.FeatureStatus`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-REGISTRY`.

Manifest signature (s).

```
(*values)
```

Definition. String-valued support status used by the feature registry.

Contract (D, C, H, R, X). Feature names and metadata are explicit, finite, and validated before registration or lookup. Registry queries do not infer support that is absent from the committed feature record.

Guarantees (E, P, B, K). Registry results reproduce the committed metadata and support status. They are descriptive records, not runtime capability probes or publication evidence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused test module is `tests/test_certificates_registry.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 6 and 62.

C.1G · `StageSpec`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.StageSpec`. Reflected implementation `komorebi_math.unified.StageSpec`. The same runtime object is also available through `komorebi_math.unified.StageSpec`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-UNIFIED`.

Manifest signature (s).

```
(stage: 'UnifiedStage', meaning: 'str', implemented_in_alpha: 'bool', module: 'str') -> None
```

Definition. Immutable descriptor for one stage of the unified workflow.

Contract (D, C, H, R, X). Stage records use the fixed unified workflow vocabulary. A unified system delegates to its component stages and therefore requires every supplied component to satisfy its own public contract. Public fields are `stage`, `meaning`, `implemented_in_alpha`, `module`.

Guarantees (E, P, B, K). The unified layer preserves the outputs and limitations of the component stages. It provides one workflow vocabulary rather than a second implementation of the underlying mathematics.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused test module is `tests/test_unified_extensions_cli.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 62 and 64.

C.1G · UnifiedStage

Identity (q, a, t, k). Public research-manifest route `komorebi_math.UnifiedStage`. Reflected implementation `komorebi_math.unified.UnifiedStage`. The same runtime object is also available through `komorebi_math.unified.UnifiedStage`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-UNIFIED`.

Manifest signature (s).

```
(*values)
```

Definition. String-valued enumeration of the unified workflow stages.

Contract (D, C, H, R, X). Stage records use the fixed unified workflow vocabulary. A unified system delegates to its component stages and therefore requires every supplied component to satisfy its own public contract.

Guarantees (E, P, B, K). The unified layer preserves the outputs and limitations of the component stages. It provides one workflow vocabulary rather than a second implementation of the underlying mathematics.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused test module is `tests/test_unified_extensions_cli.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 62 and 64.

C.1G · UnifiedSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.UnifiedSystem`. Reflected implementation `komorebi_math.unified.UnifiedSystem`. The same runtime object is also available through `komorebi_math.unified.UnifiedSystem`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `class`. Profile `C1G-UNIFIED`.

Manifest signature (s).

```
(grammar: 'OperatorGrammar | None' = None, realization: 'OperatorRealization | None' = None, seed_system:
    ↪  'SeedSystem | None' = None, packet_system: 'PacketSystem | None' = None, operators: 'Mapping[str, Any]' =
    ↪  <factory>, refinement_tower: 'RefinementTower | None' = None, metadata: 'dict[str, Any]' = <factory>) -> None
```

Definition. One finite system expressed in the common seed and packet language.

Contract (D, C, H, R, X). Stage records use the fixed unified workflow vocabulary. A unified system delegates to its component stages and therefore requires every supplied component to satisfy its own public contract. Public fields are `grammar`, `realization`, `seed_system`, `packet_system`, `operators`, `refinement_tower`, `metadata`. Principal public operations are `validate`, `analyze`, `block_operator`, `refine_coordinates`, `coarsen_coordinates`, `obstruction`, `summary`.

Guarantees (E, P, B, K). The unified layer preserves the outputs and limitations of the component stages. It provides one workflow vocabulary rather than a second implementation of the underlying mathematics.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. The focused test module is `tests/test_unified_extensions_cli.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 62 and 64.

C.1G · feature

Identity (q, a, t, k). Public research-manifest route `komorebi_math.feature`. Reflected implementation `komorebi_math.registry.feature`. The same runtime object is also available through `komorebi_math.registry.feature`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REGISTRY`.

Manifest signature (s).

```
(key: 'str') -> 'FeatureSpec'
```

Definition. Return one registered feature specification by key.

Contract (D, C, H, R, X). Feature names and metadata are explicit, finite, and validated before registration or lookup. Registry queries do not infer support that is absent from the committed feature record.

Guarantees (E, P, B, K). Registry results reproduce the committed metadata and support status. They are descriptive records, not runtime capability probes or publication evidence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_block13_cli_api.py`, `tests/test_block14_cli_api.py`, `tests/test_certificates_registry.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 6 and 62.

C.1G · features

Identity (q, a, t, k). Public research-manifest route `komorebi_math.features`. Reflected implementation `komorebi_math.registry.features`. The same runtime object is also available through `komorebi_math.registry.features`. The root route is governed by `[RESEARCH]` policy `pre-beta-additive`. It does not enlarge the frozen stable compatibility promise. Manifest kind `function`. Profile `C1G-REGISTRY`.

Manifest signature (s).

```
() -> 'tuple[FeatureSpec, ...]'
```

Definition. Return every registered feature specification in key order.

Contract (D, C, H, R, X). Feature names and metadata are explicit, finite, and validated before registration or lookup. Registry queries do not infer support that is absent from the committed feature record.

Guarantees (E, P, B, K). Registry results reproduce the committed metadata and support status. They are descriptive records, not runtime capability probes or publication evidence.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this root export. Focused test modules include `tests/test_certificates_registry.py`, `tests/test_unified_extensions_cli.py`. The independent verifier for the root namespace checks root identity, any published family alias, the recorded implementation owner, the committed signature, and representative construction or invocation. The source validator for the root namespace checks exact card order, record counts, unique anchors, and preservation of the technical content. See Chapters 6 and 62.

C.2 `komorebi_math.coordinates`: 237 entries

C.2A Exact linear algebra, combinatorial transforms, packet orderings, tensor transport, finite fields, and normalization: 60 entries

This domain section documents the exact finite machinery beneath higher coordinate constructions. It covers rational matrix conversion and elimination, Stirling and Lah connection maps, finite binomial and Möbius transforms, deterministic index permutations, tensor and covector transport, prime-field coordinate changes, and normalized generating-function coefficients. The cards distinguish exact algebraic identities from resource limits caused by dense materialization. They also make exponential subset and tensor growth explicit rather than hiding it behind a convenient constructor.

C.2A · `ExactLinearSystem`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.ExactLinearSystem`. Reflected implementation `komorebi_math.coordinates.exact.ExactLinearSystem`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-EXACT`.

Manifest signature (`s`).

```
(consistent: 'bool', rank: 'int', solution: 'Vector | None', nullspace_basis: 'tuple[Vector, ...]', pivot_columns:
   ↪  'tuple[int, ...]', residual: 'Vector') -> None
```

Definition. Exact result for a possibly rectangular linear system.

Contract (`D, C, H, R, X`). The record stores consistency, rank, one affine representative when one exists, a right-nullspace basis, pivot columns, and an exact residual. An inconsistent system has `solution=None`. The record reports the solver result and does not recompute it.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `FiniteFieldCoordinateTransform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.FiniteFieldCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.modular.FiniteFieldCoordinateTransform`. The same runtime object is also available through root route `komorebi_math.FiniteFieldCoordinateTransform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-MODULAR`.

Manifest signature (`s`).

```
(source: 'str', target: 'str', matrix: 'ModularMatrix', prime: 'int', theorem: 'str' = 'CC.M1', description: 'str'
   ↪  = '') -> None
```

Definition. An exact linear coordinate transform over `F_prime`.

Contract (`D, C, H, R, X`). The modulus must be prime, source and target names must be nonempty, and the matrix must be nonempty and rectangular. Entries are reduced modulo the prime. `apply` checks vector length. `inverse` requires a square nonsingular matrix. `then` requires a common prime and matching coordinate names. `certificate` records exact finite-field validation.

Guarantees (E, P, B, K). Arithmetic is exact modulo the selected prime. Certificate validity is based on exact modular products, not a probabilistic numerical test. Primality screening uses trial division, and dense inversion is cubic in matrix dimension in modular arithmetic.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16 and 64.

C.2A · `apply_lowering_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.apply_lowering_polynomial`. Reflected implementation `komorebi_math.coordinates.normalized.apply_lowering_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NORMALIZED`.

Manifest signature (s).

```
(coefficients: 'Sequence[Scalar]', polynomial: 'Iterable[Scalar]') -> 'Vector'
```

Definition. Apply a polynomial in the canonical lowering operator.

Contract (D, C, H, R, X). The lowering polynomial must contain at least one exact coefficient. The finite prefix is shortened by the polynomial degree. If the prefix is too short, the result is empty.

Guarantees (E, P, B, K). Normalization factors and outputs are exact rational values. The explicit diagonal transform is stored as a dense square matrix, while coefficient conversion itself is linear after construction. Applying a lowering polynomial uses work proportional to the output length times the polynomial length.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 21, and 64.

C.2A · `as_matrix`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.as_matrix`. Reflected implementation `komorebi_math.coordinates.exact.as_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(rows: 'Iterable[Iterable[Scalar]]') -> 'Matrix'
```

Definition. Return an immutable rectangular rational matrix.

Contract (D, C, H, R, X). Rows may be empty, but nonempty input must be rectangular. Every entry must be an exact rational coefficient and Boolean values are rejected. Ragged rows raise `DimensionError`.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · as_vector

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.as_vector`. Reflected implementation `komorebi_math.coordinates.exact.as_vector`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(values: 'Iterable[Scalar]') -> 'Vector'
```

Definition. Return an immutable rational vector.

Contract (D, C, H, R, X). The input may be any finite iterable of integers or `Fraction` values. Boolean values and coefficients that cannot be converted to an exact rational raise `ValidationError`. The result is an immutable tuple of `Fraction` values.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · binomial_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.binomial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.binomial_transform`. The same runtime object is also available through root route `komorebi_math.binomial_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(size: 'int', *, inverse: 'bool' = False, source: 'str' = 'sequence values', target: 'str' = 'binomial transform',
    ↪ budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512,
    ↪ maximum_horizon=4096, maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the finite binomial transform or its inverse.

Contract (D, C, H, R, X). The size must be positive and must fit the coordinate budget. `inverse=False` builds the lower-triangular binomial map. `inverse=True` builds its signed inverse and reverses the source and target labels.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · chinese_remainder_order

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.chinese_remainder_order`. Reflected implementation `komorebi_math.coordinates.packet.chinese_remainder_order`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (s).

```
(moduli: 'Sequence[int]') -> 'tuple[int, ...]'
```

Definition. Return flat indices ordered lexicographically by CRT residues.

Contract (D, C, H, R, X). At least one positive modulus is required and all moduli must be pairwise coprime. The output orders integers by their residue tuples in lexicographic order.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · chinese_remainder_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.chinese_remainder_transform`. Reflected implementation `komorebi_math.coordinates.packet.chinese_remainder_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (s).

```
(moduli: 'Sequence[int]') -> 'CoordinateTransform'
```

Definition. Return the permutation from integer order to CRT-residue order.

Contract (D, C, H, R, X). At least one positive modulus is required and all moduli must be pairwise coprime. The output orders integers by their residue tuples in lexicographic order.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · contragredient_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.contragredient_transform`. Reflected implementation `komorebi_math.coordinates.tensor.contragredient_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (s).

```
(transform: 'CoordinateTransform') -> 'CoordinateTransform'
```

Definition. Return the induced transform on covector coordinates.

Contract (D, C, H, R, X). The coordinate transform must be square and invertible. Covectors use the inverse transpose of the vector coordinate matrix. Dimension failures propagate as explicit exceptions.

Guarantees (E, P, B, K). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `convert_normalized_coefficients`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.convert_normalized_coefficients`. Reflected implementation `komorebi_math.coordinates.normalized.convert_normalized_coefficients`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NORMALIZED`.

Manifest signature (s).

```
(coefficients: 'Sequence[Scalar]', source: 'WeightedMonomialBasis', target: 'WeightedMonomialBasis', *, budget:
    ↪ 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512,
    ↪ maximum_horizon=4096, maximum_exact_entries=1000000)) -> 'Vector'
```

Definition. Convert a finite coefficient vector between normalized bases.

Contract (D, C, H, R, X). The finite coefficient sequence is converted to exact rationals. Empty input returns an empty tuple. Nonempty input applies the degree-matched normalization change.

Guarantees (E, P, B, K). Normalization factors and outputs are exact rational values. The explicit diagonal transform is stored as a dense square matrix, while coefficient conversion itself is linear after construction. Applying a lowering polynomial uses work proportional to the output length times the polynomial length.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 21, and 64.

C.2A · `coordinate_pairing`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.coordinate_pairing`. Reflected implementation `komorebi_math.coordinates.tensor.coordinate_pairing`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (`S`).

```
(covector: 'Sequence[Scalar]', vector: 'Sequence[Scalar]') -> 'Fraction'
```

Definition. Return the exact natural pairing of coordinate components.

Contract (`D, C, H, R, X`). Vector and covector component sequences must have equal length. Values are converted to exact rationals and a mismatch raises `DimensionError`.

Guarantees (`E, P, B, K`). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `determinant`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.determinant`. Reflected implementation `komorebi_math.coordinates.exact.determinant`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`S`).

```
(matrix: 'Matrix') -> 'Fraction'
```

Definition. Return the exact determinant.

Contract (`D, C, H, R, X`). The matrix must be square. Rectangular input raises `DimensionError`. The determinant of the empty square matrix is one.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `digit_reversal_order`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.digit_reversal_order`. Reflected implementation `komorebi_math.coordinates.packet.digit_reversal_order`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (`S`).

```
(length: 'int', radix: 'int' = 2) -> 'tuple[int, ...]'
```

Definition. Return the fixed-width base-radix digit-reversal order.

Contract (`D, C, H, R, X`). Length and radix must be positive integers, and the length must be an exact power of the radix. Otherwise `DimensionError` or `ValidationError` is raised.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `digit_reversal_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.digit_reversal_transform`. Reflected implementation `komorebi_math.coordinates.packet.digit_reversal_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (s).

```
(length: 'int', radix: 'int' = 2) -> 'CoordinateTransform'
```

Definition. Return the exact fixed-width digit-reversal permutation.

Contract (D, C, H, R, X). Length and radix must be positive integers, and the length must be an exact power of the radix. Otherwise `DimensionError` or `ValidationError` is raised.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `direct_sum_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.direct_sum_transform`. Reflected implementation `komorebi_math.coordinates.tensor.direct_sum_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (s).

```
(left: 'CoordinateTransform', right: 'CoordinateTransform') -> 'CoordinateTransform'
```

Definition. Return the block-diagonal direct sum of two coordinate transforms.

Contract (D, C, H, R, X). The function forms the exact block-diagonal direct sum. Rectangular transforms are allowed and the output dimensions are the sums of the input dimensions.

Guarantees (E, P, B, K). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates

checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · divisor_zeta_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.divisor_zeta_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.divisor_zeta_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(size: 'int', *, inverse: 'bool' = False, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return zeta or Möbius coordinates on the divisibility poset.

Contract (D, C, H, R, X). The size must be positive and must fit the coordinate budget. The forward map uses divisibility incidence. The inverse uses the classical Möbius function on quotient indices.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · falling_factorial_to_monomial_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.falling_factorial_to_monomial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.falling_factorial_to_monomial_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return falling-factorial coefficients in the monomial basis.

Contract (D, C, H, R, X). The degree must be a nonnegative integer and the coordinate budget must permit a square matrix of size `degree+1`. The returned `CoordinateTransform` is an exact Stirling or Lah connection matrix with named source and target coefficient systems.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · forward_difference_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.forward_difference_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.forward_difference_transform`. The same runtime object is also available through root route `komorebi_math.forward_difference_transform` and stable routes `komorebi_math.stable.forward_difference_transform`, `komorebi_math.v1.forward_difference_transform`, and `komorebi_math.api.v1.forward_difference_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Only the listed stable routes carry the frozen 1.x compatibility promise. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(size: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Map sampled values `f(0),...,f(N)` to forward differences at zero.

Contract (D, C, H, R, X). The size must be positive and must fit the coordinate budget. The analysis map sends consecutive samples to forward differences at zero. The evaluation map is its exact inverse.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · identity_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.identity_matrix`. Reflected implementation `komorebi_math.coordinates.exact.identity_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(size: 'int') -> 'Matrix'
```

Definition. Return a rational identity matrix.

Contract (D, C, H, R, X). The size must be a nonnegative integer. Negative sizes raise `DimensionError`. Size zero returns the empty exact identity.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · inverse_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.inverse_matrix`. Reflected implementation `komorebi_math.coordinates.exact.inverse_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(matrix: 'Matrix') -> 'Matrix'
```

Definition. Return the exact inverse of a nonsingular square matrix.

Contract (D, C, H, R, X). The matrix must be square and nonsingular. Rectangular input raises `DimensionError`. Singular input raises `ValidationError` after exact Gauss-Jordan reduction.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · lah_number

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.lah_number`. Reflected implementation `komorebi_math.coordinates.combinatorial.lah_number`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(n: 'int', k: 'int') -> 'int'
```

Definition. Return the unsigned Lah number `L(n,k)`.

Contract (D, C, H, R, X). `n` and `k` must be nonnegative integers and Boolean values are invalid. Values with `k>n` return zero, with the conventional exception `L(0,0)=1`. The result is an exact Python integer.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · matrix_add

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.matrix_add`. Reflected implementation `komorebi_math.coordinates.exact.matrix_add`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(left: 'Matrix', right: 'Matrix') -> 'Matrix'
```

Definition. Add matrices with equal shape.

Contract (D, C, H, R, X). Both matrices must have identical shape. A mismatch raises `DimensionError`. Addition is entrywise over exact rational coefficients.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `matrix_from_columns`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.matrix_from_columns`. Reflected implementation `komorebi_math.coordinates.exact.matrix_from_columns`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(columns: 'Sequence[Sequence[Scalar]]') -> 'Matrix'
```

Definition. Build a matrix from column vectors.

Contract (D, C, H, R, X). All column vectors must have the same length and every value must be exactly rational. Unequal lengths raise `DimensionError`. An empty column list returns the empty matrix.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `matrix_multiply`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.matrix_multiply`. Reflected implementation `komorebi_math.coordinates.exact.matrix_multiply`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`S`).

```
(left: 'Matrix', right: 'Matrix') -> 'Matrix'
```

Definition. Return the exact matrix product.

Contract (`D, C, H, R, X`). The left column count must equal the right row count. A mismatch raises `DimensionError`. Empty and zero-width cases retain their mathematically defined finite shapes.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `matrix_power`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.matrix_power`. Reflected implementation `komorebi_math.coordinates.exact.matrix_power`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`S`).

```
(matrix: 'Matrix', exponent: 'int') -> 'Matrix'
```

Definition. Return a nonnegative exact matrix power.

Contract (`D, C, H, R, X`). The matrix must be square and the exponent must be a nonnegative integer that is not Boolean. Invalid shape raises `DimensionError` and an invalid exponent raises `ValidationError`.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `matrix_rank`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.matrix_rank`. Reflected implementation `komorebi_math.coordinates.exact.matrix_rank`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`S`).

```
(matrix: 'Matrix') -> 'int'
```

Definition. Return exact rational rank.

Contract (`D, C, H, R, X`). The result is the number of pivot columns in exact reduced row echelon form. No tolerance or numerical rank threshold is used.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices,

and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `matrix_shape`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.matrix_shape`. Reflected implementation `komorebi_math.coordinates.exact.matrix_shape`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(matrix: 'Matrix') -> 'tuple[int, int]'
```

Definition. Return the matrix shape.

Contract (D, C, H, R, X). The input is an immutable rectangular matrix. The empty matrix has shape `(0, 0)`. The function performs no numerical coercion.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `matrix_subtract`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.matrix_subtract`. Reflected implementation `komorebi_math.coordinates.exact.matrix_subtract`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(left: 'Matrix', right: 'Matrix') -> 'Matrix'
```

Definition. Subtract matrices with equal shape.

Contract (D, C, H, R, X). Both matrices must have identical shape. A mismatch raises `DimensionError`. Subtraction is entrywise over exact rational coefficients.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · matrix_vector_multiply

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.matrix_vector_multiply`. Reflected implementation `komorebi_math.coordinates.exact.matrix_vector_multiply`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (s).

```
(matrix: 'Matrix', vector: 'Sequence[Scalar]') -> 'Vector'
```

Definition. Return an exact matrix vector product.

Contract (D, C, H, R, X). The vector length must equal the matrix column count. Inputs are converted to exact rationals and a mismatch raises `DimensionError`.

Guarantees (E, P, B, K). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · mobius_integer

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.mobius_integer`. Reflected implementation `komorebi_math.coordinates.combinatorial.mobius_integer`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(value: 'int') -> 'int'
```

Definition. Return the classical Möbius function of a positive integer.

Contract (D, C, H, R, X). The argument must be a positive integer that is not Boolean. Invalid input raises `ValidationError`. The result is exactly `-1`, `0`, or `1`.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · monomial_to_falling_factorial_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.monomial_to_falling_factorial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.monomial_to_falling_factorial_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return monomial coefficients in the falling-factorial basis.

Contract (D, C, H, R, X). The degree must be a nonnegative integer and the coordinate budget must permit a square matrix of size `degree+1`. The returned `CoordinateTransform` is an exact Stirling or Lah connection matrix with named source and target coefficient systems.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `monomial_to_rising_factorial_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.monomial_to_rising_factorial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.monomial_to_rising_factorial_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return monomial coefficients in the rising-factorial basis.

Contract (D, C, H, R, X). The degree must be a nonnegative integer and the coordinate budget must permit a square matrix of size `degree+1`. The returned `CoordinateTransform` is an exact Stirling or Lah connection matrix with named source and target coefficient systems.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `newton_evaluation_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.newton_evaluation_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.newton_evaluation_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(size: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Map forward differences at zero to values at consecutive integers.

Contract (D, C, H, R, X). The size must be positive and must fit the coordinate budget. The analysis map sends consecutive samples to forward differences at zero. The evaluation map is its exact inverse.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `normalization_change_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.normalization_change_transform`. Reflected implementation `komorebi_math.coordinates.normalized.normalization_change_transform`. The same runtime object is also available through root route `komorebi_math.normalization_change_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NORMALIZED`.

Manifest signature (s).

```
(source: 'WeightedMonomialBasis', target: 'WeightedMonomialBasis', degree: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the diagonal map preserving the underlying formal series.

Contract (D, C, H, R, X). Source and target must be weighted monomial bases. Degree must pass the coordinate budget. The result is the diagonal map with entry `target.gamma(n)/source.gamma(n)`.

Guarantees (E, P, B, K). Normalization factors and outputs are exact rational values. The explicit diagonal transform is stored as a dense square matrix, while coefficient conversion itself is linear after construction. Applying a lowering polynomial uses work proportional to the output length times the polynomial length.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 21, and 64.

C.2A · `nullspace`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.nullspace`. Reflected implementation `komorebi_math.coordinates.exact.nullspace`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`s`).

```
(matrix: 'Matrix') -> 'tuple[Vector, ...]'
```

Definition. Return an exact basis for the right nullspace.

Contract (`D, C, H, R, X`). The function returns a deterministic exact basis for the right nullspace using free columns from reduced row echelon form. A matrix with zero columns has an empty basis.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `pairing_invariant`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.pairing_invariant`. Reflected implementation `komorebi_math.coordinates.tensor.pairing_invariant`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (`s`).

```
(covector: 'Sequence[Scalar]', vector: 'Sequence[Scalar]', transform: 'CoordinateTransform') -> 'bool'
```

Definition. Return whether vector and covector transport preserves their pairing.

Contract (`D, C, H, R, X`). The vector must match the transform source dimension and the covector must have the same length. The result compares source and transported pairings by exact equality.

Guarantees (`E, P, B, K`). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `reduce_exact_transform_mod_prime`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.reduce_exact_transform_mod_prime`. Reflected implementation `komorebi_math.coordinates.modular.reduce_exact_transform_mod_prime`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-MODULAR`.

Manifest signature (s).

```
(transform: 'CoordinateTransform', prime: 'int') -> 'FiniteFieldCoordinateTransform'
```

Definition. Reduce a rational coordinate transform modulo a prime.

Contract (D, C, H, R, X). The modulus must be prime and every rational denominator in the exact transform must be invertible modulo that prime. Failure raises `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact modulo the selected prime. Certificate validity is based on exact modular products, not a probabilistic numerical test. Primality screening uses trial division, and dense inversion is cubic in matrix dimension in modular arithmetic.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16 and 64.

C.2A · `residue_class_order`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.residue_class_order`. Reflected implementation `komorebi_math.coordinates.packet.residue_class_order`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (s).

```
(length: 'int', modulus: 'int') -> 'tuple[int, ...]'
```

Definition. Return indices grouped by residue modulo `modulus`.

Contract (D, C, H, R, X). Length and modulus must be positive integers. Indices are grouped by residue class in increasing residue order, with the original order preserved within each lane.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `residue_class_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.residue_class_transform`. Reflected implementation `komorebi_math.coordinates.packet.residue_class_transform`. The same runtime object is also available through root route `komorebi_math.residue_class_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (`s`).

```
(length: 'int', modulus: 'int') -> 'CoordinateTransform'
```

Definition. Return the exact polyphase permutation into residue-lane order.

Contract (`D, C, H, R, X`). Length and modulus must be positive integers. Indices are grouped by residue class in increasing residue order, with the original order preserved within each lane.

Guarantees (`E, P, B, K`). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `rising_factorial_to_monomial_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.rising_factorial_to_monomial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.rising_factorial_to_monomial_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (`s`).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return rising-factorial coefficients in the monomial basis.

Contract (`D, C, H, R, X`). The degree must be a nonnegative integer and the coordinate budget must permit a square matrix of size `degree+1`. The returned `CoordinateTransform` is an exact Stirling or Lah connection matrix with named source and target coefficient systems.

Guarantees (`E, P, B, K`). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `rising_to_falling_factorial_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.rising_to_falling_factorial_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.rising_to_falling_factorial_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (`s`).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return rising-factorial coordinates in the falling-factorial basis.

Contract (`D, C, H, R, X`). The degree must be a nonnegative integer and the coordinate budget must permit a square matrix of size `degree+1`. The returned `CoordinateTransform` is an exact Stirling or Lah connection matrix with named source and target coefficient systems.

Guarantees (`E, P, B, K`). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `rref`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.rref`. Reflected implementation `komorebi_math.coordinates.exact.rref`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`s`).

```
(matrix: 'Matrix') -> 'tuple[Matrix, tuple[int, ...]]'
```

Definition. Return reduced row echelon form and pivot columns.

Contract (`D, C, H, R, X`). The input must be rectangular. The function returns exact reduced row echelon form together with pivot-column indices. Pivot selection is deterministic from top to bottom and left to right.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `solve_linear_system`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.solve_linear_system`. Reflected implementation `komorebi_math.coordinates.exact.solve_linear_system`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`s`).

```
(matrix: 'Matrix', right_hand_side: 'Sequence[Scalar]') -> 'ExactLinearSystem'
```

Definition. Solve a rational linear system and return one affine representative.

Contract (`D, C, H, R, X`). The right-hand-side length must equal the matrix row count. The solver accepts rectangular systems, returns one representative with free variables set to zero, and returns a nullspace basis. Inconsistency is represented in the result rather than raised as an exception.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `sorted_coordinate_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.sorted_coordinate_transform`. Reflected implementation `komorebi_math.coordinates.packet.sorted_coordinate_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (`s`).

```
(length: 'int', key: 'Callable[[int], object]', *, source: 'str' = 'original index order', target: 'str' =
    ↪  'key-sorted index order') -> 'CoordinateTransform'
```

Definition. Return a custom exact index permutation obtained from a deterministic key.

Contract (`D, C, H, R, X`). Length must be positive. The key must deterministically order every index from zero through `length-1`. The function returns the exact permutation induced by Python sorting.

Guarantees (`E, P, B, K`). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `stirling_first_signed`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.stirling_first_signed`. Reflected implementation `komorebi_math.coordinates.combinatorial.stirling_first_signed`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(n: 'int', k: 'int') -> 'int'
```

Definition. Return the signed Stirling number of the first kind `s(n,k)`.

Contract (D, C, H, R, X). `n` and `k` must be nonnegative integers and Boolean values are invalid. Values with `k>n` return zero, with the conventional exception `L(0,0)=1`. The result is an exact Python integer.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · stirling_first_unsigned

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.stirling_first_unsigned`. Reflected implementation `komorebi_math.coordinates.combinatorial.stirling_first_unsigned`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(n: 'int', k: 'int') -> 'int'
```

Definition. Return the unsigned Stirling number of the first kind.

Contract (D, C, H, R, X). `n` and `k` must be nonnegative integers and Boolean values are invalid. Values with `k>n` return zero, with the conventional exception `L(0,0)=1`. The result is an exact Python integer.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · stirling_second

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.stirling_second`. Reflected implementation `komorebi_math.coordinates.combinatorial.stirling_second`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(n: 'int', k: 'int') -> 'int'
```

Definition. Return the Stirling number of the second kind `S(n,k)`.

Contract (D, C, H, R, X). `n` and `k` must be nonnegative integers and Boolean values are invalid. Values with `k>n` return zero, with the conventional exception `L(0,0)=1`. The result is an exact Python integer.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `subset_zeta_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.subset_zeta_transform`. Reflected implementation `komorebi_math.coordinates.combinatorial.subset_zeta_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(rank: 'int', *, inverse: 'bool' = False, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the subset zeta or Möbius transform on a Boolean lattice.

Contract (D, C, H, R, X). The Boolean-lattice rank must be a nonnegative integer. The materialized dimension is `2**rank`, so the coordinate budget is checked against a square matrix of that size. The inverse flag selects subset Möbius inversion.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `tensor_axis_permutation_order`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.tensor_axis_permutation_order`. Reflected implementation `komorebi_math.coordinates.packet.tensor_axis_permutation_order`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (s).

```
(shape: 'Sequence[int]', axes: 'Sequence[int]') -> 'tuple[int, ...]'
```

Definition. Return the flat-index order induced by a tensor-axis permutation.

Contract (D, C, H, R, X). The shape must be nonempty with positive entries. `axes` must be a complete permutation of the tensor axes. Flat indices use row-major lexicographic order.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `tensor_axis_permutation_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.tensor_axis_permutation_transform`. Reflected implementation `komorebi_math.coordinates.packet.tensor_axis_permutation_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PACKET`.

Manifest signature (s).

```
(shape: 'Sequence[int]', axes: 'Sequence[int]') -> 'CoordinateTransform'
```

Definition. Return the exact coordinate permutation for transposed tensor axes.

Contract (D, C, H, R, X). The shape must be nonempty with positive entries. `axes` must be a complete permutation of the tensor axes. Flat indices use row-major lexicographic order.

Guarantees (E, P, B, K). Every result is an exact finite permutation or its exact `CoordinateTransform`. Construction uses no numerical tolerance or optional backend. Storage is linear in the number of indices. Sorting-based orders require `O(n log n)` comparisons, while direct residue and digit orders require linear work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_numeric_packet.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 13, 18, and 64.

C.2A · `tensor_coordinate_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.tensor_coordinate_transform`. Reflected implementation `komorebi_math.coordinates.tensor.tensor_coordinate_transform`. The same runtime object is also available through root route `komorebi_math.tensor_coordinate_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (`s`).

```
(transform: 'CoordinateTransform', variance: 'Sequence[Variance]') -> 'CoordinateTransform'
```

Definition. Return the induced transform on flattened tensor components.

Contract (`D, C, H, R, X`). The base coordinate transform must be square. Each variance entry must be exactly `contravariant` or `covariant`. Tensor axes are flattened lexicographically and a rank-zero tensor uses the one-dimensional identity.

Guarantees (`E, P, B, K`). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `tensor_product_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.tensor_product_transform`. Reflected implementation `komorebi_math.coordinates.tensor.tensor_product_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (`s`).

```
(left: 'CoordinateTransform', right: 'CoordinateTransform') -> 'CoordinateTransform'
```

Definition. Return the Kronecker product of two coordinate transforms.

Contract (`D, C, H, R, X`). The function forms the exact Kronecker product of the two coordinate matrices. Source and target labels are combined in the same left-to-right tensor order.

Guarantees (`E, P, B, K`). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `transform_sequence`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.transform_sequence`. Reflected implementation `komorebi_math.coordinates.combinatorial.transform_sequence`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-COMBINATORIAL`.

Manifest signature (s).

```
(values: 'Sequence[int | Fraction]', transform: 'CoordinateTransform') -> 'tuple[Fraction, ...]'
```

Definition. Apply a coordinate transform to a finite exact sequence.

Contract (D, C, H, R, X). The sequence length must equal the transform source dimension. A mismatch raises `DimensionError`. Values are transported through the exact coordinate map and returned as `Fraction` values.

Guarantees (E, P, B, K). Coefficients and transforms are exact integers or `Fraction` values. Materialized transforms use quadratic storage in their matrix dimension. For subset transforms the dimension is exponential in rank, so the explicit matrix has `4**rank` entries. The coordinate budget rejects oversized requests before construction.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_combinatorial.py` and `verification/block14_general_coordinate_audit.py` cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 17, 18, and 64.

C.2A · `transport_bilinear_form`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.transport_bilinear_form`. Reflected implementation `komorebi_math.coordinates.tensor.transport_bilinear_form`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (s).

```
(form: 'Iterable[Iterable[Scalar]]', transform: 'CoordinateTransform') -> 'Matrix'
```

Definition. Return the target matrix `C^(-T) G C^(-1)` of a bilinear form.

Contract (D, C, H, R, X). The form and coordinate map must be square with matching dimension. The result uses the exact congruence `C^{-T} G C^{-1}`.

Guarantees (E, P, B, K). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `transport_covector`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.transport_covector`. Reflected implementation `komorebi_math.coordinates.tensor.transport_covector`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (s).

```
(covector: 'Sequence[Scalar]', transform: 'CoordinateTransform') -> 'Vector'
```

Definition. Transport covector components to the target coordinates.

Contract (D, C, H, R, X). The coordinate transform must be square and invertible. Covectors use the inverse transpose of the vector coordinate matrix. Dimension failures propagate as explicit exceptions.

Guarantees (E, P, B, K). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `transport_operator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.transport_operator`. Reflected implementation `komorebi_math.coordinates.tensor.transport_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (s).

```
(operator: 'Iterable[Iterable[Scalar]]', transform: 'CoordinateTransform') -> 'Matrix'
```

Definition. Return `C A C^(-1)` in target coordinates.

Contract (D, C, H, R, X). The operator and coordinate map must be square with matching source dimension. The result is the exact similarity transform `C A C^{-1}`.

Guarantees (E, P, B, K). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `transport_rectangular_operator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.transport_rectangular_operator`. Reflected implementation `komorebi_math.coordinates.tensor.transport_rectangular_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (`s`).

```
(operator: 'Iterable[Iterable[Scalar]]', domain_transform: 'CoordinateTransform', codomain_transform:
   ↪  'CoordinateTransform') -> 'Matrix'
```

Definition. Transport a linear map by `C_codomain A C_domain^(-1)`.

Contract (`D, C, H, R, X`). Both domain and codomain coordinate maps must be square. Operator columns must match the domain dimension and rows must match the codomain dimension.

Guarantees (`E, P, B, K`). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `transport_tensor_components`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.transport_tensor_components`. Reflected implementation `komorebi_math.coordinates.tensor.transport_tensor_components`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-TENSOR`.

Manifest signature (`s`).

```
(components: 'Sequence[Scalar]', transform: 'CoordinateTransform', variance: 'Sequence[Variance]') -> 'Vector'
```

Definition. Transport flattened tensor components between coordinates.

Contract (`D, C, H, R, X`). The base coordinate transform must be square. Each variance entry must be exactly `contravariant` or `covariant`. Tensor axes are flattened lexicographically and a rank-zero tensor uses the one-dimensional identity.

Guarantees (`E, P, B, K`). Transport is exact over rational coefficients. Inversion and similarity or congruence operations use dense exact elimination and multiplication. Kronecker dimensions multiply, so explicit tensor matrices can grow exponentially with tensor rank. No sparse or lazy representation is implied.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_tensor_modular.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 16, 54, and 64.

C.2A · `transpose`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.transpose`. Reflected implementation `komorebi_math.coordinates.exact.transpose`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`s`).

```
(matrix: 'Matrix') -> 'Matrix'
```

Definition. Return the matrix transpose.

Contract (`D, C, H, R, X`). The input must use the exact rectangular matrix representation. The operation swaps row and column positions and preserves every coefficient exactly.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2A · `zero_matrix`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.zero_matrix`. Reflected implementation `komorebi_math.coordinates.exact.zero_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-EXACT`.

Manifest signature (`s`).

```
(rows: 'int', columns: 'int') -> 'Matrix'
```

Definition. Return a rational zero matrix.

Contract (`D, C, H, R, X`). Row and column counts must be nonnegative integers. Negative dimensions raise `DimensionError`. Zero dimensions are represented by empty tuples in the corresponding direction.

Guarantees (`E, P, B, K`). All arithmetic is exact over `Fraction`. No tolerance, floating backend, accelerator, network, or filesystem access is used. Entrywise work is linear in matrix size, dense multiplication is cubic for square matrices, and elimination-based operations are cubic in arithmetic-operation count. Rational numerator and denominator sizes may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_exact.py` and the independent verifier for exact coordinates cover the applicable construction, inverse, invariant, failure, and resource behavior. The source validator for exact coordinates checks the exact signature, implementation identity, domain facade, alias routes, and anchor. See Chapters 15, 16, and 64.

C.2B Classical polynomial families, interpolation, and exact operator calculus: 73 entries

This section documents the exact polynomial-coordinate layer as one connected subsystem. It starts with immutable coefficient arithmetic and graded family objects, then covers classical and recurrence-defined polynomial families, finite interpolation bases, family-to-family connection matrices, affine substitution, and operator matrices for differentiation, integration, multiplication, finite differences, and coordinate transport. Every card uses the same ascending-degree coefficient convention. The resource notes separate low-order coefficient operations from dense family conversion, where exact matrix inversion is the dominant cost.

C.2B · PolynomialCoordinateOperator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.PolynomialCoordinateOperator`. Reflected implementation `komorebi_math.coordinates.calculus.PolynomialCoordinateOperator`. The same runtime object is also available through `komorebi_math.PolynomialCoordinateOperator`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-POLY-OPERATOR`.

Manifest signature (s).

```
(name: 'str', source_family: 'str', target_family: 'str', source_degree: 'int', target_degree: 'int', matrix:
   ↪  'Matrix', theorem: 'str' = 'CC.01') -> None
```

Definition. Store and apply a finite exact operator matrix between two polynomial-family truncations.

Contract (D, C, H, R, X). The declared source and target degrees determine the required matrix shape. Names must be nonempty. `apply` checks the input dimension through exact matrix multiplication. `compose` requires matching family names and truncation degrees. `certificate` records exact shape validation under the supplied theorem identifier.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · PolynomialFamily

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.PolynomialFamily`. Reflected implementation `komorebi_math.coordinates.polynomials.PolynomialFamily`. The same runtime object is also available through `komorebi_math.PolynomialFamily`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
(name: 'str', rule: 'Callable[[int], Polynomial]') -> None
```

Definition. Represent a graded exact polynomial basis through a degree-indexed construction rule.

Contract (D, C, H, R, X). The name and rule are stored without evaluating the full family. `polynomial(degree)` accepts only nonnegative integer degrees and requires the rule to return a polynomial of exact graded degree with a nonzero leading coefficient. `coefficient_matrix(degree)` places those basis polynomials in monomial-coordinate columns.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `PolynomialFamilyCatalog`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.PolynomialFamilyCatalog`. Reflected implementation `komorebi_math.coordinates.classical.PolynomialFamilyCatalog`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
(families: 'tuple[PolynomialFamily, ...]') -> None
```

Definition. Provide deterministic lookup for the built-in exact graded polynomial families.

Contract (`D, C, H, R, X`). The catalog stores an ordered tuple of `PolynomialFamily` objects. `names()` preserves that order. `get(name)` normalizes case and punctuation, accepts the documented short aliases, and raises `ValidationError` for an unknown family.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `affine_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.affine_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.affine_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`s`).

```
(scale: 'Scalar', shift: 'Scalar') -> 'Polynomial'
```

Definition. Return the affine polynomial `shift + scale*x`.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · affine_substitution_coordinate_operator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.affine_substitution_coordinate_operator`. Reflected implementation `komorebi_math.coordinates.calculus.affine_substitution_coordinate_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (s).

```
(family: 'PolynomialFamily', degree: 'int', *, scale: 'Scalar' = 1, shift: 'Scalar' = 0, budget: 'CoordinateBudget'
   ↪ = CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
   ↪ maximum_exact_entries=1000000)) -> 'PolynomialCoordinateOperator'
```

Definition. Return the degree-preserving substitution `p(x)->p(scale*x+shift)`.

Contract (D, C, H, R, X). The family and degree must satisfy the polynomial-operator contract. Scale and shift are exact rational values. The result is square and represents substitution within the same family.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · affine_substitution_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.affine_substitution_transform`. Reflected implementation `komorebi_math.coordinates.classical.affine_substitution_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-TRANSFORM`.

Manifest signature (s).

```
(family: 'PolynomialFamily', degree: 'int', *, scale: 'Scalar' = 1, shift: 'Scalar' = 0, budget: 'CoordinateBudget'
   ↪ = CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
   ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return the coordinates of `p(scale*x+shift)` in one family.

Contract (D, C, H, R, X). The family must be valid through the requested nonnegative degree. Scale and shift must convert to exact rational values. The coordinate budget bounds the square matrix, and the result maps coefficients of `p(x)` to coefficients of `p(scale*x+shift)` in the same family.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · appell_polynomial

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.appell_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.appell_polynomial`. The same spelling also appears at `komorebi_math.appell_polynomial`, but that route resolves to `komorebi_math.analytic.appell` and is not an alias of this coordinate-domain object. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int', values_at_zero: 'Sequence[Scalar]') -> 'Polynomial'
```

Definition. Return one Appell polynomial from the values `P_n(0)`.

Contract (D, C, H, R, X). Degree must be nonnegative. The seed must contain values through the requested degree and its degree-zero value must be nonzero. The result uses the exact Appell identity based on the values at zero.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · appell_polynomial_family

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.appell_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.appell_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
(values_at_zero: 'Sequence[Scalar]', *, name: 'str' = 'custom Appell polynomials') -> 'PolynomialFamily'
```

Definition. Return a finite-seed Appell family.

Contract (D, C, H, R, X). The seed must be nonempty and start with a nonzero value. The returned family is finite-seed: requesting a degree outside the stored seed raises `DimensionError`. The optional name labels the coordinate family and does not change the coefficients.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · bernoulli_number

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.bernoulli_number`. Reflected implementation `komorebi_math.coordinates.classical.bernoulli_number`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(index: 'int') -> 'Fraction'
```

Definition. Return the Bernoulli number with convention `B_1=-1/2`.

Contract (D, C, H, R, X). The index must be a nonnegative integer. The recurrence uses the convention `B_1=-1/2` and returns an exact `Fraction`.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · bernoulli_polynomial

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.bernoulli_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.bernoulli_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the Bernoulli polynomial `B_degree(x)`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · bernoulli_polynomial_family

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.bernoulli_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.bernoulli_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded Bernoulli polynomial family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `bernstein_basis`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.bernstein_basis`. Reflected implementation `komorebi_math.coordinates.classical.bernstein_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-INTERPOLATION`.

Manifest signature (s).

```
(degree: 'int') -> 'FiniteBasis'
```

Definition. Return the fixed-degree Bernstein basis of polynomials through `degree`.

Contract (D, C, H, R, X). Degree must be nonnegative. The result contains all degree-fixed Bernstein polynomials from index zero through the degree, padded to one common ambient dimension. It is a `FiniteBasis`, not a graded `PolynomialFamily`.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `bernstein_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.bernstein_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.bernstein_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int', index: 'int') -> 'Polynomial'
```

Definition. Return `binom(degree,index)x^index(1-x)^(degree-index)`.

Contract (D, C, H, R, X). Degree and index must be nonnegative integers, and the index cannot exceed the degree. The returned coefficient tuple represents the fixed-degree Bernstein polynomial in ascending monomial order.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `binomial_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.binomial_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.binomial_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the binomial polynomial `binom(x,degree)`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `binomial_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.binomial_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.binomial_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded binomial-polynomial family.

Contract (`D, C, H, R, X`). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `chebyshev_t_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.chebyshev_t_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.chebyshev_t_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the Chebyshev polynomial `T_degree`.

Contract (`D, C, H, R, X`). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `chebyshev_t_polynomial_family`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.chebyshev_t_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.chebyshev_t_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded Chebyshev `T` family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · chebyshev_u_polynomial

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.chebyshev_u_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.chebyshev_u_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the Chebyshev polynomial `U_degree`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · chebyshev_u_polynomial_family

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.chebyshev_u_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.chebyshev_u_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded Chebyshev `U` family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `classical_polynomial_catalog`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.classical_polynomial_catalog`. Reflected implementation `komorebi_math.coordinates.classical.classical_polynomial_catalog`. The same runtime object is also available through `komorebi_math.classical_polynomial_catalog`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamilyCatalog'
```

Definition. Return the built-in exact graded polynomial-family catalog.

Contract (D, C, H, R, X). Returns the fixed built-in catalog of fifteen exact graded families. The catalog order is deterministic and includes monomial, Euler, Fibonacci, factorial, Bernoulli, Lucas, Pell, Chebyshev, Legendre, Hermite, and Laguerre families.

Guarantees (E, P, B, K). The result is deterministic and exact over integers and `Fraction` values. Dense coordinate work can require quadratic storage and cubic arithmetic-operation cost. No floating tolerance or optional numerical backend is consulted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `connection_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.connection_transform`. Reflected implementation `komorebi_math.coordinates.polynomials.connection_transform`. The same runtime object is also available through `komorebi_math.connection_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-TRANSFORM`.

Manifest signature (`S`).

```
(source: 'PolynomialFamily', target: 'PolynomialFamily', degree: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Return target coordinates of source basis vectors through one degree.

Contract (`D, C, H, R, X`). Source and target must be `PolynomialFamily` objects and degree must satisfy the coordinate budget. Both families must be valid graded bases through that degree. The returned matrix is `M_target^{-1} M_source`.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `constant_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.constant_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.constant_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`S`).

```
(value: 'Scalar') -> 'Polynomial'
```

Definition. Return one exact constant polynomial.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `derivative_coordinate_operator`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.derivative_coordinate_operator`. Reflected implementation `komorebi_math.coordinates.calculus.derivative_coordinate_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (`s`).

```
(family: 'PolynomialFamily', degree: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'PolynomialCoordinateOperator'
```

Definition. Return differentiation in one graded polynomial family.

Contract (`D, C, H, R, X`). The family and degree must satisfy the polynomial-operator contract. The result is a square operator on the declared truncation and carries theorem identifier `CC.02`.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · `derivative_operator_in_family`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.derivative_operator_in_family`. Reflected implementation `komorebi_math.coordinates.polynomials.derivative_operator_in_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-TRANSFORM`.

Manifest signature (`s`).

```
(family: 'PolynomialFamily', degree: 'int') -> 'Matrix'
```

Definition. Return the derivative operator in one graded polynomial basis.

Contract (`D, C, H, R, X`). The family must be valid through the requested degree. The monomial derivative matrix is conjugated by the family coefficient matrix. The returned dense matrix acts on coefficient vectors of length `degree+1`.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `euler_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.euler_polynomial`. Reflected implementation `komorebi_math.coordinates.polynomials.euler_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the Euler polynomial from `2e^(xt)/(e^t+1)`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `euler_polynomial_at_zero`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.euler_polynomial_at_zero`. Reflected implementation `komorebi_math.coordinates.polynomials.euler_polynomial_at_zero`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(index: 'int') -> 'Fraction'
```

Definition. Return `E_index(0)` for `2e^(xt)/(e^t+1)`.

Contract (D, C, H, R, X). The index must be nonnegative. The finite recurrence returns the exact value at zero for the Euler-polynomial convention `2e^(xt)/(e^t+1)`.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `euler_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.euler_polynomial_family`. Reflected implementation `komorebi_math.coordinates.polynomials.euler_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded Euler polynomial family.

Contract (`D, C, H, R, X`). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `euler_to_fibonacci_coefficient`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.euler_to_fibonacci_coefficient`. Reflected implementation `komorebi_math.coordinates.polynomials.euler_to_fibonacci_coefficient`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(euler_degree: 'int', fibonacci_degree: 'int') -> 'Fraction'
```

Definition. Return the exact coefficient in `E_n=sum_k c_(k,n)F_(k+1)`.

Contract (`D, C, H, R, X`). Both degrees must be nonnegative. A Fibonacci degree above the Euler degree returns zero. The function combines exact Euler values at zero with the monomial-to-Fibonacci formula.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `euler_to_fibonacci_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.euler_to_fibonacci_transform`. Reflected implementation `komorebi_math.coordinates.polynomials.euler_to_fibonacci_transform`. The same runtime object is also available through `komorebi_math.euler_to_fibonacci_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-TRANSFORM`.

Manifest signature (s).

```
(degree: 'int', *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
    ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
    ↪ 'CoordinateTransform'
```

Definition. Return the Euler polynomial to Fibonacci polynomial connection.

Contract (D, C, H, R, X). Degree must fit the coordinate budget. The general family connection is computed first, then every entry is checked against the explicit coefficient formula. A disagreement raises `ValidationError` instead of returning an unchecked matrix.

Guarantees (E, P, B, K). The connection and its independent entry formula are exact rational calculations. Dense basis inversion and multiplication require cubic arithmetic-operation cost in `degree+1`, with quadratic matrix storage. Exact coefficient sizes may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `evaluation_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.evaluation_transform`. Reflected implementation `komorebi_math.coordinates.classical.evaluation_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-INTERPOLATION`.

Manifest signature (s).

```
(family: 'PolynomialFamily', nodes: 'Sequence[Scalar]', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Map polynomial-family coefficients to values at exact nodes.

Contract (D, C, H, R, X). Nodes must be nonempty and must determine the polynomial space through degree `len(nodes) -1`. The matrix evaluates each family basis polynomial at each node. A singular evaluation matrix raises `ValidationError`.

Guarantees (E, P, B, K). Evaluation entries are exact rational values. Determinant and inverse-related checks use dense exact algebra with cubic arithmetic-operation cost in the node count and quadratic storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `falling_factorial_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.falling_factorial_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.falling_factorial_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return `x^(underline degree)`.

Contract (`D, C, H, R, X`). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `falling_factorial_polynomial_family`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.falling_factorial_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.falling_factorial_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded falling-factorial family.

Contract (`D, C, H, R, X`). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `fibonacci_companion_power`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.fibonacci_companion_power`. Reflected implementation `komorebi_math.coordinates.polynomials.fibonacci_companion_power`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(power: 'int') -> 'tuple[tuple[Polynomial, Polynomial], tuple[Polynomial, Polynomial]]'
```

Definition. Return `[[x,1],[1,0]]^power` as exact polynomial entries.

Contract (D, C, H, R, X). Power must be a nonnegative integer. Binary exponentiation is applied to the polynomial companion matrix `[[x,1],[1,0]]`, with exact polynomial multiplication at every step.

Guarantees (E, P, B, K). All matrix entries are exact polynomials. Binary exponentiation uses logarithmically many 2 by 2 matrix products, while polynomial coefficient work grows with the requested power. Coefficients and polynomial lengths may grow substantially.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `fibonacci_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.fibonacci_polynomial`. Reflected implementation `komorebi_math.coordinates.polynomials.fibonacci_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(index: 'int') -> 'Polynomial'
```

Definition. Return the standard Fibonacci polynomial `F_index(x)`.

Contract (D, C, H, R, X). The index must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `fibonacci_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.fibonacci_polynomial_family`. Reflected implementation `komorebi_math.coordinates.polynomials.fibonacci_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded basis `G_n(x)=F_(n+1)(x)`.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `finite_difference_coordinate_operator`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.finite_difference_coordinate_operator`. Reflected implementation `komorebi_math.coordinates.calculus.finite_difference_coordinate_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (s).

```
(family: 'PolynomialFamily', degree: 'int', *, step: 'Scalar' = 1, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'PolynomialCoordinateOperator'
```

Definition. Return `Delta_h p(x)=p(x+h)-p(x)` in one family.

Contract (D, C, H, R, X). The step must be an exact nonzero rational value. A zero step raises `ValidationError`. The result is the degree-preserving forward-difference operator `p(x+step)-p(x)`.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · `get_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.get_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.get_polynomial_family`. The same runtime object is also available through `komorebi_math.get_polynomial_family`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
(name: 'str') -> 'PolynomialFamily'
```

Definition. Return one built-in graded polynomial family by name or short alias.

Contract (D, C, H, R, X). The name is normalized by case and alphanumeric content. Documented short aliases resolve to the corresponding built-in family. Unknown names raise `ValidationError`.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `hermite_physicists_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.hermite_physicists_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.hermite_physicists_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the physicists' Hermite polynomial `H_degree`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `hermite_physicists_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.hermite_physicists_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.hermite_physicists_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the physicists' Hermite family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `hermite_probabilists_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.hermite_probabilists_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.hermite_probabilists_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the probabilists' Hermite polynomial `He_degree`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `hermite_probabilists_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.hermite_probabilists_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.hermite_probabilists_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the probabilists' Hermite family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · integral_coordinate_operator

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.integral_coordinate_operator`. Reflected implementation `komorebi_math.coordinates.calculus.integral_coordinate_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (s).

```
(family: 'PolynomialFamily', degree: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'PolynomialCoordinateOperator'
```

Definition. Return zero-constant integration in one graded polynomial family.

Contract (D, C, H, R, X). The family and degree must satisfy the polynomial-operator contract. The result maps degree `d` coefficients to degree `d+1` coefficients using the zero-constant antiderivative and carries theorem identifier `CC.03`.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · interpolation_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.interpolation_transform`. Reflected implementation `komorebi_math.coordinates.classical.interpolation_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-INTERPOLATION`.

Manifest signature (s).

```
(family: 'PolynomialFamily', nodes: 'Sequence[Scalar]', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Map exact node values to coefficients in a polynomial family.

Contract (D, C, H, R, X). Nodes must satisfy the evaluation-transform contract. The result is the exact inverse map from node values to family coefficients.

Guarantees (E, P, B, K). Interpolation is the exact inverse of the evaluation matrix. Dense exact inversion requires cubic arithmetic-operation cost in the node count and may increase numerator and denominator sizes.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `lagrange_interpolation_basis`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.lagrange_interpolation_basis`. Reflected implementation `komorebi_math.coordinates.classical.lagrange_interpolation_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-INTERPOLATION`.

Manifest signature (s).

```
(nodes: 'Sequence[Scalar]') -> 'FiniteBasis'
```

Definition. Return the cardinal Lagrange basis at distinct exact nodes.

Contract (D, C, H, R, X). Nodes must form a nonempty finite exact sequence with no duplicates. The returned basis is cardinal at those nodes, so evaluating basis vector `i` at node `j` gives the Kronecker delta.

Guarantees (E, P, B, K). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `laguerre_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.laguerre_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.laguerre_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the ordinary Laguerre polynomial `L_degree`.

Contract (D, C, H, R, X). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `laguerre_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.laguerre_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.laguerre_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded ordinary Laguerre family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `legendre_polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.legendre_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.legendre_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return the Legendre polynomial `P_degree`.

Contract (`D, C, H, R, X`). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `legendre_polynomial_family`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.legendre_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.legendre_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded Legendre polynomial family.

Contract (`D, C, H, R, X`). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py, tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `lucas_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.lucas_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.lucas_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (s).

```
(index: 'int') -> 'Polynomial'
```

Definition. Return `L_index(x)` with `L_0=2`, `L_1=x`.

Contract (D, C, H, R, X). The index must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `lucas_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.lucas_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.lucas_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded Lucas polynomial family.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `monomial_polynomial_family`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.monomial_polynomial_family`. Reflected implementation `komorebi_math.coordinates.polynomials.monomial_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
() -> 'PolynomialFamily'
```

Definition. Return the monomial family `1,x,x^2,...`.

Contract (`D, C, H, R, X`). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `monomial_to_fibonacci_coefficient`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.monomial_to_fibonacci_coefficient`. Reflected implementation `komorebi_math.coordinates.polynomials.monomial_to_fibonacci_coefficient`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(degree: 'int', fibonacci_degree: 'int') -> 'int'
```

Definition. Return the coefficient of `F_(k+1)` in `x^degree`.

Contract (`D, C, H, R, X`). Both degrees must be nonnegative. Degree or parity incompatibility returns zero rather than raising. Compatible cases use the exact binomial-difference formula.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `multiplication_coordinate_operator`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.multiplication_coordinate_operator`. Reflected implementation `komorebi_math.coordinates.calculus.multiplication_coordinate_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (`s`).

```
(family: 'PolynomialFamily', degree: 'int', multiplier: 'Sequence[Scalar]', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'PolynomialCoordinateOperator'
```

Definition. Return multiplication by a fixed exact polynomial.

Contract (`D, C, H, R, X`). The multiplier must be a nonempty exact coefficient sequence. The target degree increases by the multiplier degree. Matrix size and polynomial degree remain subject to the coordinate budget.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · `newton_interpolation_basis`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.newton_interpolation_basis`. Reflected implementation `komorebi_math.coordinates.classical.newton_interpolation_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-INTERPOLATION`.

Manifest signature (`s`).

```
(nodes: 'Sequence[Scalar]') -> 'FiniteBasis'
```

Definition. Return the Newton interpolation basis associated with distinct nodes.

Contract (`D, C, H, R, X`). Nodes must form a nonempty finite exact sequence with no duplicates. The basis contains cumulative products over the preceding nodes and uses the input order as part of the coordinate definition.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `operator_change_of_coordinates`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.operator_change_of_coordinates`. Reflected implementation `komorebi_math.coordinates.polynomials.operator_change_of_coordinates`. The same runtime object is also available through `komorebi_math.operator_change_of_coordinates`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-TRANSFORM`.

Manifest signature (`s`).

```
(operator_in_source: 'Matrix', source_to_target: 'CoordinateTransform') -> 'Matrix'
```

Definition. Conjugate an operator from source coordinates into target coordinates.

Contract (`D, C, H, R, X`). The operator must be square and its dimension must equal the source dimension of the coordinate transform. The result is the exact conjugate `C A C^{-1}` in target coordinates.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `operator_commutator`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.operator_commutator`. Reflected implementation `komorebi_math.coordinates.calculus.operator_commutator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (`s`).

```
(left: 'Matrix', right: 'Matrix') -> 'Matrix'
```

Definition. Return the exact commutator `left*right-right*left`.

Contract (`D, C, H, R, X`). Both matrices must have the same square shape. Unequal or rectangular shapes raise `DimensionError`. The result is computed exactly as `left*right-right*left`.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · `operator_matrix_between_families`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.operator_matrix_between_families`. Reflected implementation `komorebi_math.coordinates.classical.operator_matrix_between_families`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-TRANSFORM`.

Manifest signature (`s`).

```
(source: 'PolynomialFamily', target: 'PolynomialFamily', source_degree: 'int', target_degree: 'int', operator:
    ↪ 'Callable[[Polynomial], Polynomial]', *, name: 'str' = 'polynomial operator', budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'Matrix'
```

Definition. Return an exact matrix for a polynomial operator between two families.

Contract (`D, C, H, R, X`). Source and target degrees must be nonnegative and fit the coordinate budget. The callable is applied to every source basis polynomial. Each image must fit the declared target degree, otherwise `DimensionError` is raised during padding.

Guarantees (`E, P, B, K`). The returned matrix is exact. Compilation materializes every image column and inverts the target family matrix, with cubic dense-algebra cost in the target dimension plus the cost of the supplied rule.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `pell_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.pell_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.pell_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(index: 'int') -> 'Polynomial'
```

Definition. Return `P_index(x)` with `P_0=0`, `P_1=1` and `P_n=2xP_(n-1)+P_(n-2)`.

Contract (`D, C, H, R, X`). The index must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `pell_polynomial_family`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.pell_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.pell_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (s).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded basis `P_(n+1)(x)` of Pell polynomials.

Contract (D, C, H, R, X). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (E, P, B, K). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `polynomial_add`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.polynomial_add`. Reflected implementation `komorebi_math.coordinates.polynomials.polynomial_add`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (s).

```
(left: 'Sequence[Scalar]', right: 'Sequence[Scalar]') -> 'Polynomial'
```

Definition. Add exact polynomials stored in ascending degree order.

Contract (D, C, H, R, X). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (E, P, B, K). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `polynomial_compose_affine`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.polynomial_compose_affine`. Reflected implementation `komorebi_math.coordinates.classical.polynomial_compose_affine`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`S`).

```
(polynomial: 'Sequence[Scalar]', *, scale: 'Scalar' = 1, shift: 'Scalar' = 0) -> 'Polynomial'
```

Definition. Return `polynomial(scale*x+shift)` exactly.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Polynomial convolution or affine composition uses quadratic coefficient work in the represented degrees and linear output storage. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `polynomial_derivative`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_derivative`. Reflected implementation `komorebi_math.coordinates.polynomials.polynomial_derivative`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`S`).

```
(polynomial: 'Sequence[Scalar]') -> 'Polynomial'
```

Definition. Differentiate an exact polynomial.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `polynomial_evaluate`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_evaluate`. Reflected implementation `komorebi_math.coordinates.polynomials.polynomial_evaluate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`s`).

```
(polynomial: 'Sequence[Scalar]', value: 'Scalar') -> 'Fraction'
```

Definition. Evaluate an exact polynomial by Horner's method.

Contract (`D, C, H, R, X`). The coefficient sequence is interpreted in ascending degree order and the evaluation point must convert to an exact rational value. Horner evaluation returns one exact `Fraction`.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `polynomial_integral`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_integral`. Reflected implementation `komorebi_math.coordinates.calculus.polynomial_integral`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (`s`).

```
(polynomial: 'Sequence[Scalar]', constant: 'Scalar' = 0) -> 'Polynomial'
```

Definition. Return one exact antiderivative.

Contract (`D, C, H, R, X`). The coefficient sequence is interpreted in ascending degree order and converted to exact rational values. The supplied constant becomes the degree-zero coefficient. The output degree is one greater than the input representation.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · `polynomial_multiply`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_multiply`. Reflected implementation `komorebi_math.coordinates.polynomials.polynomial_multiply`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`s`).

```
(left: 'Sequence[Scalar]', right: 'Sequence[Scalar]') -> 'Polynomial'
```

Definition. Multiply exact polynomials.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Polynomial convolution or affine composition uses quadratic coefficient work in the represented degrees and linear output storage. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `polynomial_operator`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_operator`. Reflected implementation `komorebi_math.coordinates.calculus.polynomial_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (`s`).

```
(source: 'PolynomialFamily', target: 'PolynomialFamily', source_degree: 'int', target_degree: 'int', rule:
    ↪ 'Callable[[Polynomial], Polynomial]', *, name: 'str', theorem: 'str' = 'CC.O1', budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'PolynomialCoordinateOperator'
```

Definition. Compile a polynomial rule into coordinates of two families.

Contract (`D, C, H, R, X`). Source and target families, truncation degrees, and the rule must define images that fit the target space. The name is required. The function compiles the rule through `operator_matrix_between_families` and returns a shape-checked `PolynomialCoordinateOperator`.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2B · `polynomial_scale`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_scale`. Reflected implementation `komorebi_math.coordinates.polynomials.polynomial_scale`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`s`).

```
(polynomial: 'Sequence[Scalar]', scalar: 'Scalar') -> 'Polynomial'
```

Definition. Scale an exact polynomial.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `polynomial_shift`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_shift`. Reflected implementation `komorebi_math.coordinates.polynomials.polynomial_shift`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`s`).

```
(polynomial: 'Sequence[Scalar]', steps: 'int' = 1) -> 'Polynomial'
```

Definition. Multiply a polynomial by `x^steps`.

Contract (`D, C, H, R, X`). The coefficient sequence is interpreted in ascending degree order. `steps` must be a nonnegative integer. The output is normalized by removing trailing zero coefficients while retaining a canonical zero polynomial.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `polynomial_subtract`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.polynomial_subtract`. Reflected implementation `komorebi_math.coordinates.classical.polynomial_subtract`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-PRIMITIVE`.

Manifest signature (`s`).

```
(left: 'Sequence[Scalar]', right: 'Sequence[Scalar]') -> 'Polynomial'
```

Definition. Subtract exact polynomials.

Contract (`D, C, H, R, X`). Inputs are finite coefficient sequences in ascending degree order and must convert to exact rational values. The result is an immutable coefficient tuple with trailing zeros removed, except that the zero polynomial retains one zero coefficient.

Guarantees (`E, P, B, K`). Arithmetic is exact over `Fraction`. Addition, scaling, shifting, differentiation, integration, and Horner evaluation are linear in coefficient count. No tolerance, symbolic service, accelerator, network, or filesystem is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `rising_factorial_polynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.rising_factorial_polynomial`. Reflected implementation `komorebi_math.coordinates.classical.rising_factorial_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(degree: 'int') -> 'Polynomial'
```

Definition. Return `x^(overline degree)`.

Contract (`D, C, H, R, X`). The degree must be a nonnegative integer. The returned immutable tuple stores exact coefficients in ascending monomial order and follows the recurrence or closed formula named in the definition.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `rising_factorial_polynomial_family`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.rising_factorial_polynomial_family`. Reflected implementation `komorebi_math.coordinates.classical.rising_factorial_polynomial_family`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-FAMILY`.

Manifest signature (`s`).

```
() -> 'PolynomialFamily'
```

Definition. Return the graded rising-factorial family.

Contract (`D, C, H, R, X`). The constructor returns a `PolynomialFamily` whose degree rule is exact and graded. Later calls to `polynomial(degree)` reject negative or noninteger degrees and verify that the leading coefficient is nonzero at the declared degree.

Guarantees (`E, P, B, K`). The construction uses integer and rational arithmetic only. Recurrence and coefficient generation are finite and deterministic for the requested degree. Runtime is polynomial in the requested prefix size, while exact coefficient magnitudes may grow rapidly for some families.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_classical.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 15, 17, 18, and 64.

C.2B · `secant_euler_from_fibonacci_coordinates`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.secant_euler_from_fibonacci_coordinates`. Reflected implementation `komorebi_math.coordinates.polynomials.secant_euler_from_fibonacci_coordinates`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-CLASSICAL`.

Manifest signature (`s`).

```
(index: 'int') -> 'Fraction'
```

Definition. Recover the signed secant Euler number from Fibonacci coordinates.

Contract (`D, C, H, R, X`). Index must be nonnegative through the delegated Euler-to-Fibonacci transform. The function evaluates the Fibonacci expansion at `x=1/2` and rescales by `2^index` to recover the signed secant Euler number.

Guarantees (`E, P, B, K`). The returned value is exact. The path computes a dense degree-index connection transform, so arithmetic-operation cost is cubic in the truncation size before the final evaluation. No floating approximation is used.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 17, 18, 21, and 64.

C.2B · `transport_polynomial_operator`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.transport_polynomial_operator`. Reflected implementation `komorebi_math.coordinates.calculus.transport_polynomial_operator`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route is not part of the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-POLY-OPERATOR`.

Manifest signature (s).

```
(operator: 'PolynomialCoordinateOperator', source_family: 'PolynomialFamily', target_family: 'PolynomialFamily',
   ↪ *, budget: 'CoordinateBudget' = CoordinateBudget(maximum_matrix_dimension=512,
   ↪ maximum_polynomial_degree=512, maximum_horizon=4096, maximum_exact_entries=1000000)) ->
   ↪ 'PolynomialCoordinateOperator'
```

Definition. Transport an operator between two graded polynomial-family coordinates.

Contract (`D, C, H, R, X`). The input operator must act within the declared source family. Separate domain and codomain connection transforms are built at the source and target degrees. The rectangular operator is then transported exactly into the target family.

Guarantees (`E, P, B, K`). All coefficients and certificates are exact. Dense family matrices use quadratic storage and inversion or conjugation can require cubic arithmetic-operation cost in the truncation dimension. The coordinate budget limits declared matrix dimensions and polynomial degrees. Exact coefficients may grow.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this domain export. `tests/test_coordinates_general_calculus.py`, `tests/test_coordinates_polynomials.py` and the independent verifier for polynomial coordinates cover the applicable formula, basis, roundtrip, operator, failure, and resource behavior. The source validator for polynomial coordinates checks the exact signature, implementation identity, domain facade, root-name collisions, and anchor. See Chapters 18, 32, and 64.

C.2C Coordinate systems, frames, recurrences, realizations, and persistence: 104 entries

This coordinate section documents the additional public contracts in the `komorebi_math.coordinates` manifest. It starts with the shared representations and exact coordinate abstractions, then records numerical frame systems, recurrence coordinates, finite realizations, state-space changes, and the portable envelope routes. The section completes the namespace without promoting research exports into the frozen stable tier.

Contract family	Cards
Exact coordinate infrastructure	35
Analysis, synthesis, and frame algebra	8
Numerical transforms and modal coordinates	7
Recurrence defects, families, and shift operators	29
Realizations and state-space coordinates	18
Portable coordinate records	7
Total	**104**

The exact and numerical paths are intentionally distinguished. Rational basis, recurrence, realization, and state-space objects make finite exact claims. Analysis and synthesis frames and named numerical transforms use NumPy and state their tolerance-qualified guarantees. Portable loaders validate data envelopes and resource limits before object reconstruction.

`RecurrenceModel.synthesize` uses the four committed fields of `RecurrenceCoordinateRecord`. A regression test checks analysis followed by synthesis on a nonhomogeneous Fibonacci prefix. This guards against the `TypeError` caused by supplying an obsolete fifth constructor field.

C.2C · `AffineCoordinateTransform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.AffineCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.affine.AffineCoordinateTransform`. The same runtime object is also available through `komorebi_math.AffineCoordinateTransform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-AFFINE`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Matrix', offset: 'Vector', theorem: 'str' = 'CC.F1', description: 'str' =
   ↪  '') -> None
```

Definition. An exact affine map `y=A x+b` between equal-dimensional spaces.

Contract (D, C, H, R, X). All coordinates are converted to exact rational values. Affine matrices must be square with an offset of matching length. Barycentric vertices must form a nondegenerate simplex. Composition, inversion, and conversion reject incompatible dimensions or singular linear parts. The principal public operations are `dimension`, `invertible`, `apply`, `inverse`, `then`, `homogeneous_matrix`, and `certificate`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `AnalysisSynthesisBlocks`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.AnalysisSynthesisBlocks`. Reflected implementation `komorebi_math.coordinates.analysis_synthesis.AnalysisSynthesisBlocks`. The same runtime object is also available through `komorebi_math.AnalysisSynthesisBlocks`, and `komorebi_math.stable.AnalysisSynthesisBlocks`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-NUMERIC`.

Manifest signature (s).

```
(system: "'AnalysisSynthesisSystem'", groups: 'tuple[tuple[int, ...], ...]', blocks: 'tuple[tuple[np.ndarray,
   ↪  ...], ...]', operator: 'np.ndarray') -> None
```

Definition. Packet blocks of one operator under a declared analysis and synthesis atlas.

Contract (D, C, H, R, X). Inputs are finite NumPy arrays with compatible rectangular shapes. A system requires the supplied synthesis map to be a left inverse of analysis within the declared tolerance. Partitions must cover valid coefficient indices without overlap, and operator blocks must reconstruct the original operator within tolerance. The principal public operations are `reconstruct` and `certificate`.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block16_analysis_synthesis.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · `AnalysisSynthesisCoefficientBlocks`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.AnalysisSynthesisCoefficientBlocks`. Reflected implementation `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisCoefficientBlocks`. The same runtime object is also available through `komorebi_math.AnalysisSynthesisCoefficientBlocks`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-ALGEBRA`.

Manifest signature (s).

```
(mapping: 'AnalysisSynthesisMap', source_partition: 'CoefficientPartition', target_partition:
   ↪  'CoefficientPartition') -> None
```

Definition. Small target-by-source blocks derived from a coefficient lift.

Contract (D, C, H, R, X). Numerical matrices must have compatible finite shapes and satisfy the declared reconstruction law within tolerance. Gauge projections, coefficient lifts, partitions, adjoints, blocks, sums, and compositions retain explicit domain and codomain systems and reject incompatible presentations. The principal public operations are `assemble`, `reblock`, `physical_block`, `then`, and `certificate`.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · `AnalysisSynthesisGauge`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.AnalysisSynthesisGauge`. Reflected implementation `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisGauge`. The same runtime object is also available through `komorebi_math.AnalysisSynthesisGauge`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-ALGEBRA`.

Manifest signature (s).

```
(system: 'AnalysisSynthesisSystem') -> None
```

Definition. Gauge and quotient calculus for one numerical presentation.

Contract (D, C, H, R, X). Numerical matrices must have compatible finite shapes and satisfy the declared reconstruction law within tolerance. Gauge projections, coefficient lifts, partitions, adjoints, blocks, sums, and compositions retain explicit domain and codomain systems and reject incompatible presentations. The principal public operations are `analysis`, `synthesis`, `source`, `coordinates`, `source_dimension`, `coordinate_dimension`, `tolerance`, and `coefficient_projection`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · `AnalysisSynthesisMap`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.AnalysisSynthesisMap`. Reflected implementation `komorebi_math.coordinates.frame_algebra.AnalysisSynthesisMap`. The same runtime object is also available through `komorebi_math.AnalysisSynthesisMap`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-ALGEBRA`.

Manifest signature (s).

```
(domain: 'AnalysisSynthesisSystem', codomain: 'AnalysisSynthesisSystem', operator: 'np.ndarray', theorem: 'str' =
    ↪  'KM-AS-MAP-01') -> None
```

Definition. A physical linear map and its canonical coefficient lift.

Contract (D, C, H, R, X). Numerical matrices must have compatible finite shapes and satisfy the declared reconstruction law within tolerance. Gauge projections, coefficient lifts, partitions, adjoints, blocks, sums, and compositions retain explicit domain and codomain systems and reject incompatible presentations. The principal public operations are `identity`, `tolerance`, `coefficient_lift`, `reconstruct`, `apply_source`, `apply_coefficients`, `then`, and `compose`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · `AnalysisSynthesisSystem`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.AnalysisSynthesisSystem`. Reflected implementation `komorebi_math.coordinates.analysis_synthesis.AnalysisSynthesisSystem`. The same runtime object is also available through `komorebi_math.AnalysisSynthesisSystem`, and `komorebi_math.stable.AnalysisSynthesisSystem`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-NUMERIC`.

Manifest signature (s).

```
(analysis: 'np.ndarray', synthesis: 'np.ndarray', source: 'str' = 'source', coordinates: 'str' = 'coordinates',
    ↪  tolerance: 'float' = 1e-12, theorem: 'str' = 'KM-AS-01') -> None
```

Definition. A finite analysis map `A` and synthesis map `S` with `S A = I`.

Contract (D, C, H, R, X). Inputs are finite NumPy arrays with compatible rectangular shapes. A system requires the supplied synthesis map to be a left inverse of analysis within the declared tolerance. Partitions must cover valid coefficient indices without overlap, and operator blocks must reconstruct the original operator within tolerance. The principal public operations are `from_invertible`, `canonical_dual`, `source_dimension`, `coordinate_dimension`, `redundant`, `square`, `frame_operator`, and `analyze`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block16_analysis_synthesis.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · AtlasPath

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.AtlasPath`. Reflected implementation `komorebi_math.coordinates.basis.AtlasPath`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(systems: 'tuple[str, ...]', transform: 'CoordinateTransform') -> None
```

Definition. One composed path through a coordinate atlas.

Contract (D, C, H, R, X). Names and dimensions must be consistent. A `FiniteBasis` requires nonempty vectors of one ambient dimension and exact linear independence. Atlas edges must agree with their registered endpoint systems, while path comparison requires common endpoints. The principal public operations are `length`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · BarycentricCoordinateSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.BarycentricCoordinateSystem`. Reflected implementation `komorebi_math.coordinates.affine.BarycentricCoordinateSystem`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-AFFINE`.

Manifest signature (s).

```
(name: 'str', vertices: 'tuple[Vector, ...]') -> None
```

Definition. Barycentric coordinates of an exact nondegenerate simplex.

Contract (D, C, H, R, X). All coordinates are converted to exact rational values. Affine matrices must be square with an offset of matching length. Barycentric vertices must form a nondegenerate simplex. Composition, inversion, and conversion reject incompatible dimensions or singular linear parts. The principal public operations are `dimension`, `augmented_vertex_matrix`, `to_cartesian`, `from_cartesian`, and `certificate`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `BezoutDefectIdentity`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.BezoutDefectIdentity`. Reflected implementation `komorebi_math.coordinates.operators.BezoutDefectIdentity`. The same runtime object is also available through `komorebi_math.BezoutDefectIdentity`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-RECURRENCE-OPERATOR`.

Manifest signature (`s`).

```
(gcd: 'Vector', left_multiplier: 'Vector', right_multiplier: 'Vector', reconstructed: 'Vector', expected:
    ↪ 'Vector', valid: 'bool') -> None
```

Definition. A finite prefix reconstruction from two coprime defect streams.

Contract (`D, C, H, R, X`). Polynomial coefficients are exact and stored in ascending shift degree. Euclidean division rejects the zero polynomial. The Bezout reconstruction requires two defect polynomials with the documented coprimality and finite-prefix compatibility conditions. The principal public operations are `certificate`.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_operators.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 21, and 32.

C.2C · `CoefficientPartition`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.CoefficientPartition`. Reflected implementation `komorebi_math.coordinates.frame_algebra.CoefficientPartition`. The same runtime object is also available through `komorebi_math.CoefficientPartition`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-ALGEBRA`.

Manifest signature (`s`).

```
(dimension: 'int', groups: 'tuple[tuple[int, ...], ...]') -> None
```

Definition. A strict ordered partition of finite coefficient indices.

Contract (`D, C, H, R, X`). Numerical matrices must have compatible finite shapes and satisfy the declared reconstruction law within tolerance. Gauge projections, coefficient lifts, partitions, adjoints, blocks, sums, and compositions retain explicit domain and codomain systems and reject incompatible presentations. The principal public operations are `singletons`, `one_block`, `refines`, and `coarsens`.

Guarantees (`E, P, B, K`). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · CommutingDiagramCheck

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.CommutingDiagramCheck`. Reflected implementation `komorebi_math.coordinates.basis.CommutingDiagramCheck`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(left: 'AtlasPath', right: 'AtlasPath', valid: 'bool', difference: 'Matrix') -> None
```

Definition. Exact comparison of two paths with common endpoints.

Contract (D, C, H, R, X). Names and dimensions must be consistent. A `FiniteBasis` requires nonempty vectors of one ambient dimension and exact linear independence. Atlas edges must agree with their registered endpoint systems, while path comparison requires common endpoints. The principal public operations are `certificate`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · CoordinateAtlas

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.CoordinateAtlas`. Reflected implementation `komorebi_math.coordinates.basis.CoordinateAtlas`. The same runtime object is also available through `komorebi_math.CoordinateAtlas`, and `komorebi_math.stable.CoordinateAtlas`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(name: 'str' = 'coordinate atlas') -> None
```

Definition. A graph of exact coordinate systems and composable transforms.

Contract (D, C, H, R, X). Names and dimensions must be consistent. A `FiniteBasis` requires nonempty vectors of one ambient dimension and exact linear independence. Atlas edges must agree with their registered endpoint systems, while path comparison requires common endpoints. The principal public operations are `register_system`, `register_basis`, `register_transform`, `systems`, `transforms`, `direct_transform`, `resolve`, and `compose_path`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · CoordinateBudget

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.CoordinateBudget`. Reflected implementation `komorebi_math.coordinates.budget.CoordinateBudget`. The same runtime object is also available through `komorebi_math.CoordinateBudget`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-BUDGET`.

Manifest signature (s).

```
(maximum_matrix_dimension: 'int' = 512, maximum_polynomial_degree: 'int' = 512, maximum_horizon: 'int' = 4096,
    ↪  maximum_exact_entries: 'int' = 1000000) -> None
```

Definition. Finite limits applied before coordinate matrices are materialized.

Contract (D, C, H, R, X). Every limit must be a positive integer. The `require_matrix`, `require_degree`, and `require_horizon` methods reject work before an oversized exact object is materialized. The principal public operations are `require_matrix`, `require_degree`, and `require_horizon`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 72.

C.2C · CoordinateSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.CoordinateSystem`. Reflected implementation `komorebi_math.coordinates.basis.CoordinateSystem`. The same runtime object is also available through `komorebi_math.CoordinateSystem`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(name: 'str', dimension: 'int', kind: 'str' = 'exact', description: 'str' = '') -> None
```

Definition. Metadata for one finite exact coordinate system.

Contract (D, C, H, R, X). Names and dimensions must be consistent. A `FiniteBasis` requires nonempty vectors of one ambient dimension and exact linear independence. Atlas edges must agree with their registered endpoint systems, while path comparison requires common endpoints.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · CoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.CoordinateTransform`. Reflected implementation `komorebi_math.coordinates.transform.CoordinateTransform`. The same runtime object is also available through `komorebi_math.CoordinateTransform`, and `komorebi_math.stable.CoordinateTransform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-TRANSFORM`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Matrix', theorem: 'str', description: 'str' = '') -> None
```

Definition. An exact matrix that maps source coordinates to target coordinates.

Contract (D, C, H, R, X). The source and target labels must be nonempty and the matrix must be nonempty, square, and exactly coercible to rational entries. Application checks vector length. Inversion rejects a singular matrix, and composition requires matching intermediate labels and dimensions. The principal public operations are `source_dimension`, `target_dimension`, `square`, `determinant`, `apply`, `inverse`, `then`, and `roundtrip_valid`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · DEFAULT_COORDINATE_BUDGET

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.DEFAULT_COORDINATE_BUDGET`. Reflected implementation `komorebi_math.coordinates.budget.CoordinateBudget`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-CORE-BUDGET`.

Manifest signature (s).

```
null
```

Definition. The package default for finite coordinate dimensions, polynomial degrees, recurrence horizons, and exact-entry counts.

Contract (D, C, H, R, X). Import returns one immutable `CoordinateBudget` instance with the committed default limits. Callers may pass it unchanged or replace it with a stricter budget. Mutating the default is not supported.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 72.

C.2C · ExactAnalysisSynthesisMap

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ExactAnalysisSynthesisMap`. Reflected implementation `komorebi_math.coordinates.frame_algebra.ExactAnalysisSynthesisMap`. The same runtime object is also available through `komorebi_math.ExactAnalysisSynthesisMap`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-ALGEBRA`.

Manifest signature (s).

```
(domain: 'ExactAnalysisSynthesisSystem', codomain: 'ExactAnalysisSynthesisSystem', operator: 'Matrix', theorem:
   ↪  'str' = 'KM-AS-EXACT-MAP-01') -> None
```

Definition. An exact rational physical map and coefficient lift.

Contract (D, C, H, R, X). Matrices and vectors are converted to exact rational values. Analysis and synthesis dimensions must agree and their product must equal the exact identity. Physical maps, coefficient lifts, partitions, direct sums, tensor products, and compositions reject incompatible source or target systems. The principal public operations are `identity`, `coefficient_lift`, `reconstruct`, `apply_coefficients`, `then`, `compose`, `adjoint`, and `dual_adjoint`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · ExactAnalysisSynthesisSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ExactAnalysisSynthesisSystem`. Reflected implementation `komorebi_math.coordinates.frame_algebra.ExactAnalysisSynthesisSystem`. The same runtime object is also available through `komorebi_math.ExactAnalysisSynthesisSystem`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-FRAME-ALGEBRA`.

Manifest signature (s).

```
(analysis: 'Matrix', synthesis: 'Matrix', source: 'str' = 'source', coordinates: 'str' = 'coordinates', theorem:
   ↪  'str' = 'KM-AS-EXACT-01') -> None
```

Definition. An exact rational analysis and synthesis presentation.

Contract (D, C, H, R, X). Matrices and vectors are converted to exact rational values. Analysis and synthesis dimensions must agree and their product must equal the exact identity. Physical maps, coefficient lifts, partitions, direct sums, tensor products, and compositions reject incompatible source or target systems. The principal public operations are `from_invertible`, `canonical_dual`, `source_dimension`, `coordinate_dimension`, `redundant`, `frame_operator`, `coefficient_projection`, and `gauge_projection`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_block18_frame_algebra.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks

the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 32, and 64.

C.2C · ExactCoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ExactCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.transform.CoordinateTransform`. The same runtime object is also available through `komorebi_math.stable.ExactCoordinateTransform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-TRANSFORM`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'Matrix', theorem: 'str', description: 'str' = '') -> None
```

Definition. A compatibility alias for `CoordinateTransform` when the matrix entries are exact rational values.

Contract (D, C, H, R, X). The source and target labels must be nonempty and the matrix must be nonempty, square, and exactly coercible to rational entries. Application checks vector length. Inversion rejects a singular matrix, and composition requires matching intermediate labels and dimensions.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · FiniteBasis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.FiniteBasis`. Reflected implementation `komorebi_math.coordinates.basis.FiniteBasis`. The same runtime object is also available through `komorebi_math.FiniteBasis`, and `komorebi_math.stable.FiniteBasis`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(name: 'str', vectors: 'tuple[Vector, ...]', labels: 'tuple[str, ...]' = (), description: 'str' = '') -> None
```

Definition. A linearly independent finite basis inside a rational ambient space.

Contract (D, C, H, R, X). Names and dimensions must be consistent. A `FiniteBasis` requires nonempty vectors of one ambient dimension and exact linear independence. Atlas edges must agree with their registered endpoint systems, while path comparison requires common endpoints. The principal public operations are `dimension`, `ambient_dimension`, `matrix`, `square`, `synthesize`, `analyze`, `contains`, and `connection_to`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · FormalCoordinateChange

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.FormalCoordinateChange`. Reflected implementation `komorebi_math.coordinates.formal.FormalCoordinateChange`. The same runtime object is also available through `komorebi_math.FormalCoordinateChange`, and `komorebi_math.stable.FormalCoordinateChange`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-FORMAL`.

Manifest signature (s).

```
(name: 'str', coefficients: 'Vector', source: 'str' = 'source formal coordinate', target: 'str' = 'target formal
    ↪ coordinate') -> None
```

Definition. A finite exact jet `phi(z)=a_1 z+a_2 z^2+...`.

Contract (D, C, H, R, X). Coefficients are interpreted as a finite jet through a declared degree. A coordinate change has zero constant term and a nonzero linear coefficient. Composition and inversion truncate only at the explicit degree and reject inconsistent or singular jets. The principal public operations are `degree`, `linear_coefficient`, `truncate`, `compose`, `inverse`, `pullback_coefficients`, `pushforward_coefficients`, and `substitution_transform`. Additional methods remain listed in the class documentation.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 18, 21, and 64.

C.2C · IntertwinerSpace

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.IntertwinerSpace`. Reflected implementation `komorebi_math.coordinates.realization.IntertwinerSpace`. The same runtime object is also available through `komorebi_math.IntertwinerSpace`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(source_dimension: 'int', target_dimension: 'int', basis: 'tuple[Matrix, ...]') -> None
```

Definition. Solutions of `B S=S A` from a source to a target realization.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly. The principal public operations are `dimension`, `contains_invertible_basis_element`, and `certificate`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · LinearRealization

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.LinearRealization`. Reflected implementation `komorebi_math.coordinates.realization.LinearRealization`. The same runtime object is also available through `komorebi_math.LinearRealization`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(transition: 'Matrix', initial: 'Vector', output: 'Vector', name: 'str' = 'linear realization') -> None
```

Definition. A scalar sequence realization `a_n=h^T A^n v`.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly. The principal public operations are `dimension`, `state`, `term`, and `prefix`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · Matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.Matrix`. Reflected implementation `builtins.tuple`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The immutable row-major matrix representation used by the exact coordinate routines.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · ModalCoordinateSystem

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ModalCoordinateSystem`. Reflected implementation `komorebi_math.coordinates.numeric.ModalCoordinateSystem`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(eigenvalues: 'np.ndarray', synthesis: 'NumericCoordinateTransform', analysis: 'NumericCoordinateTransform',
    ↪ diagonal_residual: 'float') -> None
```

Definition. Numerical modal coordinates for a diagonalizable square matrix.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions. The principal public operations are `certificate`.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.2C · ModularMatrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ModularMatrix`. Reflected implementation `builtins.tuple`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The immutable row-major integer matrix representation used after reduction modulo a prime.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · ModularVector

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ModularVector`. Reflected implementation `builtins.tuple`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The immutable integer-vector representation used after reduction modulo a prime.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · NormalizedBasis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.NormalizedBasis`. Reflected implementation `komorebi_math.generating.basis.WeightedMonomialBasis`. The same runtime object is also available through `komorebi_math.NormalizedBasis`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-CORE-NORMALIZED`.

Manifest signature (s).

```
(name: 'str', gamma: 'GammaRule', *, descriptor: 'BasisDescriptor | None' = None) -> 'None'
```

Definition. A public alias for `WeightedMonomialBasis`, which records a nonzero weight for each monomial degree.

Contract (D, C, H, R, X). The basis weight at every used degree must be nonzero. Coefficient conversion multiplies or divides by those weights exactly, and basis constructors reject invalid degrees or vanishing normalization factors.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 17, 18, and 64.

C.2C · NumericCoordinateTransform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.NumericCoordinateTransform`. Reflected implementation `komorebi_math.coordinates.numeric.NumericCoordinateTransform`. The same runtime object is also available through `komorebi_math.NumericCoordinateTransform`, and `komorebi_math.stable.NumericCoordinateTransform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(source: 'str', target: 'str', matrix: 'np.ndarray', theorem: 'str' = 'CC.NM1', description: 'str' = '', tolerance:
    ↪  'float' = 1e-12) -> None
```

Definition. A finite numerical matrix between coordinate systems.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions. The principal public operations are `source_dimension`, `target_dimension`, `square`, `apply`, `inverse`, `then`, `condition_number`, and `certificate`.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.2C · `Polynomial`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.Polynomial`. Reflected implementation `builtins.tuple`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The immutable ascending-degree coefficient tuple used for exact univariate polynomials.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · `RecurrenceCoordinateRecord`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.RecurrenceCoordinateRecord`. Reflected implementation `komorebi_math.coordinates.recurrence.RecurrenceCoordinateRecord`. The same runtime object is also available through `komorebi_math.RecurrenceCoordinateRecord`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(name: 'str', coefficients: 'Vector', initial: 'Vector', defects: 'Vector') -> None
```

Definition. Initial state and forcing coordinates for one recurrence model.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons. The principal public operations are `order`, `length`, `homogeneous`, `coordinates`, `reconstruct`, `certificate`, and `as_linear_recurrence`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `RecurrenceLike`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.RecurrenceLike`. Reflected implementation `typing.Union`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The accepted recurrence specification, either an iterable of exact coefficients or a `LinearRecurrence` object.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_tensor_modular.py`, `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · `RecurrenceModel`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.RecurrenceModel`. Reflected implementation `komorebi_math.coordinates.families.RecurrenceModel`. The same runtime object is also available through `komorebi_math.RecurrenceModel`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (`s`).

```
(name: 'str', coefficients: 'Vector', initial_values: 'Vector' = (), description: 'str' = '') -> None
```

Definition. A named constant-coefficient recurrence and optional initial state.

Contract (`D, C, H, R, X`). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`. The principal public operations are `order`, `companion`, `sequence`, `analyze`, `synthesize`, `coordinate_transform_to`, and `homogeneous_basis`.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `Scalar`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.Scalar`. Reflected implementation `types.UnionType`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (`s`).

```
null
```

Definition. The exact scalar input union consisting of Python integers and rational `Fraction` values.

Contract (`D, C, H, R, X`). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (`E, P, B, K`). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · `ShiftPolynomial`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.ShiftPolynomial`. Reflected implementation `komorebi_math.coordinates.operators.ShiftPolynomial`. The same runtime object is also available through `komorebi_math.ShiftPolynomial`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-RECURRENCE-OPERATOR`.

Manifest signature (s).

```
(coefficients: 'Iterable[Scalar]', name: 'str' = 'shift polynomial') -> 'None'
```

Definition. A polynomial `q(L)` in the canonical coefficient shift operator.

Contract (D, C, H, R, X). Polynomial coefficients are exact and stored in ascending shift degree. Euclidean division rejects the zero polynomial. The Bezout reconstruction requires two defect polynomials with the documented coprimality and finite-prefix compatibility conditions. The principal public operations are `degree`, `apply`, and `multiply`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_operators.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 21, and 32.

C.2C · `StateRecovery`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.StateRecovery`. Reflected implementation `komorebi_math.coordinates.realization.StateRecovery`. The same runtime object is also available through `komorebi_math.StateRecovery`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(exact: 'bool', unique: 'bool', rank: 'int', horizon: 'int', state: 'Vector | None', predicted: 'Vector', residual:
   ↪  'Vector') -> None
```

Definition. The result of state recovery over a finite horizon.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly. The principal public operations are `certificate`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · `StateSpaceCoordinateCertificate`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.StateSpaceCoordinateCertificate`. Reflected implementation `komorebi_math.coordinates.state_space.StateSpaceCoordinateCertificate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-STATE-SPACE`.

Manifest signature (`s`).

```
(source: 'StateSpaceModel', target: 'StateSpaceModel', transform: 'CoordinateTransform', markov_count: 'int',
    ↪ valid: 'bool') -> None
```

Definition. Exact invariance record for one state coordinate change.

Contract (`D, C, H, R, X`). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance. The principal public operations are `certificate`.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · `StateSpaceModel`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.StateSpaceModel`. Reflected implementation `komorebi_math.coordinates.state_space.StateSpaceModel`. The same runtime object is also available through `komorebi_math.StateSpaceModel`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C2-STATE-SPACE`.

Manifest signature (`s`).

```
(name: 'str', transition: 'Matrix', input_matrix: 'Matrix', output_matrix: 'Matrix', feedthrough: 'Matrix') -> None
```

Definition. A finite exact state-space model `x'=Ax+Bu, y=Cx+Du`.

Contract (`D, C, H, R, X`). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance. The principal public operations are `state_dimension`, `input_dimension`, `output_dimension`, `change_coordinates`, `markov_parameter`, and `transfer_equivalent`.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · `Variance`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.Variance`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The tensor-index variance marker with the two accepted values `contravariant` and `covariant`.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_tensor_modular.py`, `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · `Vector`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.Vector`. Reflected implementation `builtins.tuple`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C2-TYPE-ALIAS`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. The immutable exact-vector representation whose entries are rational `Fraction` values.

Contract (D, C, H, R, X). This export is a runtime type or typing alias. It accepts no call contract of its own. The functions that consume it perform dimensional, exactness, variance, and domain validation at their public boundaries.

Guarantees (E, P, B, K). The alias adds no computation and no certificate. It preserves the package representation contract at constant lookup cost. Exactness and resource behavior belong to the consuming operation.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 1, 15, and 72.

C.2C · `affine_basis_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.affine_basis_transform`. Reflected implementation `komorebi_math.coordinates.affine.affine_basis_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-AFFINE`.

Manifest signature (s).

```
(origin: 'Sequence[Scalar]', basis_vectors: 'Sequence[Sequence[Scalar]]', *, local_name: 'str' = 'local affine
   ↪  coordinates', ambient_name: 'str' = 'ambient Cartesian coordinates') -> 'AffineCoordinateTransform'
```

Definition. Construct an affine chart from an origin and a square vector basis.

Contract (D, C, H, R, X). All coordinates are converted to exact rational values. Affine matrices must be square with an offset of matching length. Barycentric vertices must form a nondegenerate simplex. Composition, inversion, and conversion reject incompatible dimensions or singular linear parts.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `analyze_recurrence_coordinates`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.analyze_recurrence_coordinates`. Reflected implementation `komorebi_math.coordinates.recurrence.analyze_recurrence_coordinates`. The same runtime object is also available through `komorebi_math.analyze_recurrence_coordinates`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(values: 'Sequence[Scalar]', coefficients: 'RecurrenceLike', *, name: 'str' = 'recurrence') ->
    ↪ 'RecurrenceCoordinateRecord'
```

Definition. Analyze a finite sequence prefix in recurrence defect coordinates.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `apply_recurrence_defect`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.apply_recurrence_defect`. Reflected implementation `komorebi_math.coordinates.recurrence.apply_recurrence_defect`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(values: 'Sequence[Scalar]', coefficients: 'RecurrenceLike') -> 'Vector'
```

Definition. Compute the unique recurrence defect stream of a finite prefix.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic

arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `basis_from_matrix`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.basis_from_matrix`. Reflected implementation `komorebi_math.coordinates.basis.basis_from_matrix`. The same runtime object is also available through `komorebi_math.basis_from_matrix`, and `komorebi_math.stable.basis_from_matrix`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(name: 'str', matrix: 'Iterable[Iterable[Scalar]]', *, labels: 'Sequence[str]' = (), description: 'str' = '') ->
    ↪ 'FiniteBasis'
```

Definition. Construct a basis from a matrix whose columns are basis vectors.

Contract (D, C, H, R, X). Inputs are converted to exact rational vectors or matrices before construction. Dimension, independence, nonzero-scale, permutation, and budget conditions are checked before the returned basis or transform is accepted.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `bezout_defect_identity`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.bezout_defect_identity`. Reflected implementation `komorebi_math.coordinates.operators.bezout_defect_identity`. The same runtime object is also available through `komorebi_math.bezout_defect_identity`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-OPERATOR`.

Manifest signature (s).

```
(values: 'Sequence[Scalar]', left: 'Sequence[Scalar]', right: 'Sequence[Scalar]') -> 'BezoutDefectIdentity'
```

Definition. Reconstruct the common finite interior from two coprime defects.

Contract (D, C, H, R, X). Polynomial coefficients are exact and stored in ascending shift degree. Euclidean division rejects the zero polynomial. The Bezout reconstruction requires two defect polynomials with the documented coprimality and finite-prefix compatibility conditions.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_operators.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 21, and 32.

C.2C · `certify_state_coordinate_change`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.certify_state_coordinate_change`. Reflected implementation `komorebi_math.coordinates.state_space.certify_state_coordinate_change`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-STATE-SPACE`.

Manifest signature (s).

```
(model: 'StateSpaceModel', transform: 'CoordinateTransform', *, markov_count: 'int | None' = None) ->
    ↪ 'StateSpaceCoordinateCertificate'
```

Definition. Certify transfer invariance under an exact state coordinate change.

Contract (D, C, H, R, X). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · `companion_matrix`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.companion_matrix`. Reflected implementation `komorebi_math.coordinates.recurrence.companion_matrix`. The same runtime object is also available through `komorebi_math.companion_matrix`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(coefficients: 'RecurrenceLike') -> 'Matrix'
```

Definition. Compute the exact companion matrix for consecutive sequence states.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks

the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · compose_ordinary_series

Identity (q, a, t, k). Public research-manifest route komorebi_math.coordinates.compose_ordinary_series. Reflected implementation komorebi_math.coordinates.formal.compose_ordinary_series. No root, stable, or beta facade exports this domain-only name in the reference manifest. The komorebi_math.coordinates route is governed by [RESEARCH] policy pre-beta-additive. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind function. Profile C2-CORE-FORMAL.

Manifest signature (s).

```
(outer: 'Sequence[Scalar]', inner: 'Sequence[Scalar]', degree: 'int') -> 'Vector'
```

Definition. Compute outer(inner(z)) modulo z^(degree+1) exactly.

Contract (D, C, H, R, X). Coefficients are interpreted as a finite jet through a declared degree. A coordinate change has zero constant term and a nonzero linear coefficient. Composition and inversion truncate only at the explicit degree and reject inconsistent or singular jets.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational Fraction values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. tests/test_coordinates_general_affine_formal.py and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 18, 21, and 64.

C.2C · controllability_basis

Identity (q, a, t, k). Public research-manifest route komorebi_math.coordinates.controllability_basis. Reflected implementation komorebi_math.coordinates.state_space.controllability_basis. No root, stable, or beta facade exports this domain-only name in the reference manifest. The komorebi_math.coordinates route is governed by [RESEARCH] policy pre-beta-additive. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind function. Profile C2-STATE-SPACE.

Manifest signature (s).

```
(model: 'StateSpaceModel') -> 'FiniteBasis'
```

Definition. Compute a maximal independent basis extracted from controllability columns.

Contract (D, C, H, R, X). The exact matrices A, B, C, and D must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational Fraction values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. tests/test_coordinates_general_families_state.py and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · controllability_coordinate_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.controllability_coordinate_transform`. Reflected implementation `komorebi_math.coordinates.state_space.controllability_coordinate_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-STATE-SPACE`.

Manifest signature (s).

```
(model: 'StateSpaceModel') -> 'CoordinateTransform'
```

Definition. Map original state coordinates to a full controllability basis.

Contract (D, C, H, R, X). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · controllability_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.controllability_matrix`. Reflected implementation `komorebi_math.coordinates.state_space.controllability_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-STATE-SPACE`.

Manifest signature (s).

```
(transition: 'Iterable[Iterable[Scalar]]', input_matrix: 'Iterable[Iterable[Scalar]]', *, steps: 'int | None' =
    ↪ None) -> 'Matrix'
```

Definition. Compute the finite controllability block matrix `[B,AB,...]`.

Contract (D, C, H, R, X). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · coordinate_change_between_recurrences

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.coordinate_change_between_recurrences`. Reflected implementation `komorebi_math.coordinates.recurrence.coordinate_change_between_recurrences`. The same runtime object is also available through `komorebi_math.coordinate_change_between_recurrences`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(source_coefficients: 'RecurrenceLike', target_coefficients: 'RecurrenceLike', length: 'int', *, source_name:
   ↪ 'str' = 'source recurrence', target_name: 'str' = 'target recurrence', budget: 'CoordinateBudget' =
   ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
   ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Compute the exact finite coordinate map between recurrence models.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · custom_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.custom_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.custom_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
(coefficients: 'Sequence[Scalar]', *, initial_values: 'Sequence[Scalar]' = (), name: 'str' = 'custom recurrence',
   ↪ description: 'str' = '') -> 'RecurrenceModel'
```

Definition. Construct an arbitrary exact constant-coefficient recurrence model.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · cyclic_krylov_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.cyclic_krylov_matrix`. Reflected implementation `komorebi_math.coordinates.realization.cyclic_krylov_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(transition: 'Matrix', vector: 'Sequence[Scalar]') -> 'Matrix'
```

Definition. Compute the square cyclic Krylov matrix `[v,Av,...]`.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · defect_green_weights

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.defect_green_weights`. Reflected implementation `komorebi_math.coordinates.recurrence.defect_green_weights`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(coefficients: 'RecurrenceLike', count: 'int') -> 'Vector'
```

Definition. Compute `g_l=e_1^T C^(l-1)e_d` for `1 <= l <= count`.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · direct_sum_basis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.direct_sum_basis`. Reflected implementation `komorebi_math.coordinates.basis.direct_sum_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(left: 'FiniteBasis', right: 'FiniteBasis', *, name: 'str | None' = None) -> 'FiniteBasis'
```

Definition. Compute the external direct sum of two finite bases.

Contract (D, C, H, R, X). Inputs are converted to exact rational vectors or matrices before construction. Dimension, independence, nonzero-scale, permutation, and budget conditions are checked before the returned basis or transform is accepted.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · discrete_cosine_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.discrete_cosine_transform`. Reflected implementation `komorebi_math.coordinates.numeric.discrete_cosine_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(size: 'int', *, orthonormal: 'bool' = True, tolerance: 'float' = 1e-12) -> 'NumericCoordinateTransform'
```

Definition. Compute the type-II discrete cosine transform.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.2C · discrete_fourier_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.discrete_fourier_transform`. Reflected implementation `komorebi_math.coordinates.numeric.discrete_fourier_transform`. The same runtime object is also available through `komorebi_math.discrete_fourier_transform`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(size: 'int', *, unitary: 'bool' = True, inverse: 'bool' = False, tolerance: 'float' = 1e-12) ->
    ↪ 'NumericCoordinateTransform'
```

Definition. Compute the finite discrete Fourier coordinate transform.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.2C · euler_fibonacci_coordinates

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.euler_fibonacci_coordinates`. Reflected implementation `komorebi_math.coordinates.recurrence.euler_fibonacci_coordinates`. The same runtime object is also available through `komorebi_math.euler_fibonacci_coordinates`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(count: 'int') -> 'RecurrenceCoordinateRecord'
```

Definition. Compute exact Fibonacci companion coordinates of a signed Euler prefix.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · exponential_basis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.exponential_basis`. Reflected implementation `komorebi_math.generating.basis.exponential_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-NORMALIZED`.

Manifest signature (s).

```
(*, name: 'str' = 'exponential') -> 'WeightedMonomialBasis'
```

Definition. Compute the exponential generating-function basis `z^n/n!`.

Contract (D, C, H, R, X). The basis weight at every used degree must be nonzero. Coefficient conversion multiplies or divides by those weights exactly, and basis constructors reject invalid degrees or vanishing normalization factors.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 17, 18, and 64.

C.2C · fibonacci_factorial_basis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.fibonacci_factorial_basis`. Reflected implementation `komorebi_math.generating.basis.fibonacci_factorial_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-NORMALIZED`.

Manifest signature (s).

```
(*, name: 'str' = 'fibonacci-factorial') -> 'WeightedMonomialBasis'
```

Definition. Compute the fibonomial basis with `gamma_n=prod_(j=1)^n F_j`.

Contract (D, C, H, R, X). The basis weight at every used degree must be nonzero. Coefficient conversion multiplies or divides by those weights exactly, and basis constructors reject invalid degrees or vanishing normalization factors.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 17, 18, and 64.

C.2C · `fibonacci_numbers`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.fibonacci_numbers`. Reflected implementation `komorebi_math.coordinates.recurrence.fibonacci_numbers`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (`s`).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Compute Fibonacci numbers beginning with zero.

Contract (`D, C, H, R, X`). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `fibonacci_recurrence_model`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.fibonacci_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.fibonacci_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (`s`).

```
() -> 'RecurrenceModel'
```

Definition. Compute the Fibonacci recurrence model.

Contract (`D, C, H, R, X`). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · formal_coordinate_from_iterable

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.formal_coordinate_from_iterable`. Reflected implementation `komorebi_math.coordinates.formal.formal_coordinate_from_iterable`. The same runtime object is also available through `komorebi_math.stable.formal_coordinate_from_iterable`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-FORMAL`.

Manifest signature (s).

```
(coefficients: 'Iterable[Scalar]', *, name: 'str' = 'custom formal coordinate', source: 'str' = 'source formal
   ↪  coordinate', target: 'str' = 'target formal coordinate') -> 'FormalCoordinateChange'
```

Definition. Construct a formal coordinate change from exact coefficients.

Contract (D, C, H, R, X). Coefficients are interpreted as a finite jet through a declared degree. A coordinate change has zero constant term and a nonzero linear coefficient. Composition and inversion truncate only at the explicit degree and reject inconsistent or singular jets.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 18, 21, and 64.

C.2C · get_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.get_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.get_recurrence_model`. The same runtime object is also available through `komorebi_math.get_recurrence_model`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
(name: 'str') -> 'RecurrenceModel'
```

Definition. Compute one built-in recurrence model by normalized name.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · haar_wavelet_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.haar_wavelet_transform`. Reflected implementation `komorebi_math.coordinates.numeric.haar_wavelet_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(size: 'int', *, orthonormal: 'bool' = True, tolerance: 'float' = 1e-12) -> 'NumericCoordinateTransform'
```

Definition. Compute a complete finite Haar wavelet transform.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.2C · identity_formal_coordinate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.identity_formal_coordinate`. Reflected implementation `komorebi_math.coordinates.formal.identity_formal_coordinate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-FORMAL`.

Manifest signature (s).

```
(degree: 'int', *, name: 'str' = 'identity formal coordinate', coordinate: 'str' = 'formal coordinate') ->
    ↪ 'FormalCoordinateChange'
```

Definition. Compute the identity formal coordinate jet.

Contract (D, C, H, R, X). Coefficients are interpreted as a finite jet through a declared degree. A coordinate change has zero constant term and a nonzero linear coefficient. Composition and inversion truncate only at the explicit degree and reject inconsistent or singular jets.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 18, 21, and 64.

C.2C · intertwiner_space

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.intertwiner_space`. Reflected implementation `komorebi_math.coordinates.realization.intertwiner_space`. The same runtime object is also available through `komorebi_math.intertwiner_space`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(source: 'Matrix', target: 'Matrix') -> 'IntertwinerSpace'
```

Definition. Compute an exact basis of matrices satisfying `target*S=S*source`.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · jacobsthal_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.jacobsthal_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.jacobsthal_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
() -> 'RecurrenceModel'
```

Definition. Compute the Jacobsthal recurrence model.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · load_coordinate_object

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.load_coordinate_object`. Reflected implementation `komorebi_math.coordinates.portable.load_coordinate_object`. The same runtime object is also available through `komorebi_math.load_coordinate_object`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path') -> 'Any'
```

Definition. Load and verify one registered portable coordinate object.

Contract (D, C, H, R, X). Loading verifies the persistence envelope, digest, codec tag, version, required fields, and resource limits before reconstructing an object. Unknown tags, malformed data, unsupported versions, and digest mismatches are rejected.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py, tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · load_coordinate_record

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.load_coordinate_record`. Reflected implementation `komorebi_math.coordinates.portable.load_coordinate_record`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path') -> 'RecurrenceCoordinateRecord'
```

Definition. Load and verify recurrence defect coordinates.

Contract (D, C, H, R, X). Loading verifies the persistence envelope, digest, codec tag, version, required fields, and resource limits before reconstructing an object. Unknown tags, malformed data, unsupported versions, and digest mismatches are rejected.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py, tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · load_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.load_transform`. Reflected implementation `komorebi_math.coordinates.portable.load_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path') -> 'CoordinateTransform'
```

Definition. Load and verify one exact coordinate transform.

Contract (D, C, H, R, X). Loading verifies the persistence envelope, digest, codec tag, version, required fields, and resource limits before reconstructing an object. Unknown tags, malformed data, unsupported versions, and digest mismatches are rejected.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py, tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · lucas_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.lucas_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.lucas_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
() -> 'RecurrenceModel'
```

Definition. Compute the Lucas recurrence model.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · modal_coordinate_system

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.modal_coordinate_system`. Reflected implementation `komorebi_math.coordinates.numeric.modal_coordinate_system`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(operator: 'Any', *, state_name: 'str' = 'state coordinates', modal_name: 'str' = 'modal coordinates', tolerance:
    ↪  'float' = 1e-10) -> 'ModalCoordinateSystem'
```

Definition. Construct numerical modal coordinates for a diagonalizable operator.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.2C · observability_block_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.observability_block_matrix`. Reflected implementation `komorebi_math.coordinates.state_space.observability_block_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-STATE-SPACE`.

Manifest signature (s).

```
(transition: 'Iterable[Iterable[Scalar]]', output_matrix: 'Iterable[Iterable[Scalar]]', *, steps: 'int | None' =
    ↪  None) -> 'Matrix'
```

Definition. Construct the finite observability block matrix whose block rows are `C`, `C A`, and the successive powers through the requested horizon.

Contract (D, C, H, R, X). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · observability_coordinate_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.observability_coordinate_transform`. Reflected implementation `komorebi_math.coordinates.state_space.observability_coordinate_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-STATE-SPACE`.

Manifest signature (s).

```
(model: 'StateSpaceModel') -> 'CoordinateTransform'
```

Definition. Map state coordinates to a full output-jet coordinate system.

Contract (D, C, H, R, X). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · observability_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.observability_matrix`. Reflected implementation `komorebi_math.coordinates.realization.observability_matrix`. The same runtime object is also available through `komorebi_math.observability_matrix`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(transition: 'Matrix', output: 'Sequence[Scalar]', horizon: 'int', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'Matrix'
```

Definition. Compute rows `h^T A^n` for `0 <= n < horizon`.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · ordinary_basis

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.ordinary_basis`. Reflected implementation `komorebi_math.generating.basis.ordinary_basis`. The same runtime object is also available through `komorebi_math.ordinary_basis`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-NORMALIZED`.

Manifest signature (s).

```
(*, name: 'str' = 'ordinary') -> 'WeightedMonomialBasis'
```

Definition. Compute the ordinary generating-function basis `z^n`.

Contract (D, C, H, R, X). The basis weight at every used degree must be nonzero. Coefficient conversion multiplies or divides by those weights exactly, and basis constructors reject invalid degrees or vanishing normalization factors.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 17, 18, and 64.

C.2C · padovan_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.padovan_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.padovan_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
() -> 'RecurrenceModel'
```

Definition. Compute a standard Padovan recurrence model.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · pell_recurrence_model

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.pell_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.pell_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
() -> 'RecurrenceModel'
```

Definition. Compute the Pell recurrence model.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · permutation_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.permutation_transform`. Reflected implementation `komorebi_math.coordinates.basis.permutation_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(permutation: 'Sequence[int]', *, source: 'str' = 'original order', target: 'str' = 'permuted order') ->
    ↪ 'CoordinateTransform'
```

Definition. Compute an exact coordinate permutation.

Contract (D, C, H, R, X). Inputs are converted to exact rational vectors or matrices before construction. Dimension, independence, nonzero-scale, permutation, and budget conditions are checked before the returned basis or transform is accepted.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · polynomial_extended_gcd

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.polynomial_extended_gcd`. Reflected implementation `komorebi_math.coordinates.operators.polynomial_extended_gcd`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-OPERATOR`.

Manifest signature (s).

```
(left: 'Sequence[Scalar]', right: 'Sequence[Scalar]') -> 'tuple[Vector, Vector, Vector]'
```

Definition. Compute monic `g,u,v` with `u*left+v*right=g`.

Contract (D, C, H, R, X). Polynomial coefficients are exact and stored in ascending shift degree. Euclidean division rejects the zero polynomial. The Bezout reconstruction requires two defect polynomials with the documented coprimality and finite-prefix compatibility conditions.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_operators.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 21, and 32.

C.2C · realization_defect

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.realization_defect`. Reflected implementation `komorebi_math.coordinates.realization.realization_defect`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(realization: 'LinearRealization', target_coefficients: 'Iterable[Scalar]') -> 'LinearRealization'
```

Definition. Compute a realization of the target recurrence defect sequence.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · recover_initial_state

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.recover_initial_state`. Reflected implementation `komorebi_math.coordinates.realization.recover_initial_state`. The same runtime object is also available through `komorebi_math.recover_initial_state`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(prefix: 'Sequence[Scalar]', transition: 'Matrix', output: 'Sequence[Scalar]', *, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'StateRecovery'
```

Definition. Recover or test a state against a finite output prefix.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · recurrence_analysis_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.recurrence_analysis_transform`. Reflected implementation `komorebi_math.coordinates.recurrence.recurrence_analysis_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(coefficients: 'RecurrenceLike', length: 'int', *, name: 'str | None' = None, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Map raw values to initial state followed by recurrence defects.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · recurrence_model_catalog

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.recurrence_model_catalog`. Reflected implementation `komorebi_math.coordinates.families.recurrence_model_catalog`. The same runtime object is also available through `komorebi_math.recurrence_model_catalog`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
() -> 'tuple[RecurrenceModel, ...]'
```

Definition. Compute the built-in named recurrence models.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · recurrence_polynomial

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.recurrence_polynomial`. Reflected implementation `komorebi_math.coordinates.recurrence.recurrence_polynomial`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(coefficients: 'RecurrenceLike') -> 'Vector'
```

Definition. Compute ascending coefficients of `x^d - sum_i c_i x^i`.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · recurrence_synthesis_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.recurrence_synthesis_transform`. Reflected implementation `komorebi_math.coordinates.recurrence.recurrence_synthesis_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(coefficients: 'RecurrenceLike', length: 'int', *, name: 'str | None' = None, budget: 'CoordinateBudget' =
    ↪ CoordinateBudget(maximum_matrix_dimension=512, maximum_polynomial_degree=512, maximum_horizon=4096,
    ↪ maximum_exact_entries=1000000)) -> 'CoordinateTransform'
```

Definition. Compute the exact inverse of recurrence defect analysis.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · register_coordinate_codecs

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.register_coordinate_codecs`. Reflected implementation `komorebi_math.coordinates.portable.register_coordinate_codecs`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
() -> 'None'
```

Definition. Register the closed data-only coordinate codecs.

Contract (D, C, H, R, X). Registration installs the closed set of coordinate codecs in the package registry. Repeated registration is idempotent and does not broaden the accepted payload grammar.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py, tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · save_coordinate_object

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.save_coordinate_object`. Reflected implementation `komorebi_math.coordinates.portable.save_coordinate_object`. The same runtime object is also available through `komorebi_math.save_coordinate_object`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path', value: 'Any', *, overwrite: 'bool' = False) -> 'Path'
```

Definition. Save any registered portable coordinate object.

Contract (D, C, H, R, X). The object must belong to a registered coordinate codec. Saving writes a canonical data-only envelope with schema, version, payload, and digest fields. The destination path must be writable.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py, tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · save_coordinate_record

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.save_coordinate_record`. Reflected implementation `komorebi_math.coordinates.portable.save_coordinate_record`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path', record: 'RecurrenceCoordinateRecord', *, overwrite: 'bool' = False) -> 'Path'
```

Definition. Save recurrence defect coordinates with the package persistence envelope.

Contract (D, C, H, R, X). The object must belong to a registered coordinate codec. Saving writes a canonical data-only envelope with schema, version, payload, and digest fields. The destination path must be writable.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py, tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · save_transform

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.save_transform`. Reflected implementation `komorebi_math.coordinates.portable.save_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-PORTABLE`.

Manifest signature (s).

```
(path: 'str | Path', transform: 'CoordinateTransform', *, overwrite: 'bool' = False) -> 'Path'
```

Definition. Save one exact coordinate transform with the package persistence envelope.

Contract (D, C, H, R, X). The object must belong to a registered coordinate codec. Saving writes a canonical data-only envelope with schema, version, payload, and digest fields. The destination path must be writable.

Guarantees (E, P, B, K). The format is data-only and deterministic for a fixed object, codec version, and serializer. Digest verification detects accidental or adversarial payload changes but is not a cryptographic proof of mathematical truth. Decoding enforces the registered resource limits before large structures are accepted.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_persistence.py`, `tests/test_coordinates_normalized_persistence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 61, 64, and 72.

C.2C · `scaling_transform`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.scaling_transform`. Reflected implementation `komorebi_math.coordinates.basis.scaling_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(scales: 'Sequence[Scalar]', *, source: 'str' = 'unscaled coordinates', target: 'str' = 'scaled coordinates') ->
    ↪ 'CoordinateTransform'
```

Definition. Compute an invertible diagonal coordinate scaling.

Contract (D, C, H, R, X). Inputs are converted to exact rational vectors or matrices before construction. Dimension, independence, nonzero-scale, permutation, and budget conditions are checked before the returned basis or transform is accepted.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `sequence_coordinates_between_models`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.sequence_coordinates_between_models`. Reflected implementation `komorebi_math.coordinates.families.sequence_coordinates_between_models`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (s).

```
(values: 'Sequence[Scalar]', source: 'RecurrenceModel', target: 'RecurrenceModel') ->
    ↪ 'tuple[RecurrenceCoordinateRecord, RecurrenceCoordinateRecord, CoordinateTransform]'
```

Definition. Analyze one sequence in two recurrence systems and return the exact bridge.

Contract (D, C, H, R, X). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · signed_secant_euler_numbers

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.signed_secant_euler_numbers`. Reflected implementation `komorebi_math.coordinates.recurrence.signed_secant_euler_numbers`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Compute `E_n` from `sech(z)=sum E_n z^n/n!`.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · similarity_from_cyclic_vectors

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.similarity_from_cyclic_vectors`. Reflected implementation `komorebi_math.coordinates.realization.similarity_from_cyclic_vectors`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-REALIZATION`.

Manifest signature (s).

```
(source: 'Matrix', target: 'Matrix', source_vector: 'Sequence[Scalar]', target_vector: 'Sequence[Scalar]') ->
   ↪ 'Matrix'
```

Definition. Construct `S` with `target*S=S*source` from cyclic vectors.

Contract (D, C, H, R, X). Transition matrices are exact and square. Initial vectors and output covectors must match the state dimension. Recovery and similarity constructors require the stated observability or cyclic-rank condition. Intertwiner spaces solve the finite linear system `B S = S A` exactly.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_realization.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 32.

C.2C · `siso_state_space`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.siso_state_space`. Reflected implementation `komorebi_math.coordinates.state_space.siso_state_space`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-STATE-SPACE`.

Manifest signature (s).

```
(transition: 'Iterable[Iterable[Scalar]]', input_vector: 'Sequence[Scalar]', output_covector: 'Sequence[Scalar]',
   ↪ *, feedthrough: 'Scalar' = 0, name: 'str' = 'SISO state-space model') -> 'StateSpaceModel'
```

Definition. Construct a single-input single-output exact state-space model.

Contract (D, C, H, R, X). The exact matrices `A`, `B`, `C`, and `D` must have compatible state, input, and output dimensions. Controllability and observability coordinate constructors require full state rank. A coordinate-change certificate verifies the transformed realization and finite transfer invariance.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 40.

C.2C · `standard_basis`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.standard_basis`. Reflected implementation `komorebi_math.coordinates.basis.standard_basis`. The same runtime object is also available through `komorebi_math.standard_basis`, and `komorebi_math.stable.standard_basis`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-BASIS`.

Manifest signature (s).

```
(dimension: 'int', *, name: 'str' = 'standard') -> 'FiniteBasis'
```

Definition. Compute the standard basis of a rational vector space.

Contract (D, C, H, R, X). Inputs are converted to exact rational vectors or matrices before construction. Dimension, independence, nonzero-scale, permutation, and budget conditions are checked before the returned basis or transform is accepted.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `synthesize_recurrence_coordinates`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.synthesize_recurrence_coordinates`. Reflected implementation `komorebi_math.coordinates.recurrence.synthesize_recurrence_coordinates`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (s).

```
(record: 'RecurrenceCoordinateRecord') -> 'Vector'
```

Definition. Reconstruct a prefix from initial state and recurrence defects.

Contract (D, C, H, R, X). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (E, P, B, K). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `tensor_product_basis`

Identity (q, a, t, k). Public research-manifest route `komorebi_math.coordinates.tensor_product_basis`. Reflected implementation `komorebi_math.coordinates.basis.tensor_product_basis`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-BASIS`.

Manifest signature (`S`).

```
(left: 'FiniteBasis', right: 'FiniteBasis', *, name: 'str | None' = None) -> 'FiniteBasis'
```

Definition. Compute the tensor-product basis in lexicographic factor order.

Contract (`D, C, H, R, X`). Inputs are converted to exact rational vectors or matrices before construction. Dimension, independence, nonzero-scale, permutation, and budget conditions are checked before the returned basis or transform is accepted.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_basis.py`, `tests/test_coordinates_exact.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `translation_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.translation_transform`. Reflected implementation `komorebi_math.coordinates.affine.translation_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-CORE-AFFINE`.

Manifest signature (`S`).

```
(offset: 'Sequence[Scalar]', *, source: 'str' = 'original affine coordinates', target: 'str' = 'translated affine
   ↪ coordinates') -> 'AffineCoordinateTransform'
```

Definition. Compute an exact translation coordinate change.

Contract (`D, C, H, R, X`). All coordinates are converted to exact rational values. Affine matrices must be square with an offset of matching length. Barycentric vertices must form a nondegenerate simplex. Composition, inversion, and conversion reject incompatible dimensions or singular linear parts.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_affine_formal.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 16, and 64.

C.2C · `tribonacci_recurrence_model`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.tribonacci_recurrence_model`. Reflected implementation `komorebi_math.coordinates.families.tribonacci_recurrence_model`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-FAMILY`.

Manifest signature (`s`).

```
() -> 'RecurrenceModel'
```

Definition. Compute the Tribonacci recurrence model.

Contract (`D, C, H, R, X`). A model has a nonempty name, a positive-order exact coefficient tuple, and an optional initial state of the same order. Generation, analysis, synthesis, homogeneous bases, and model-to-model bridges enforce the requested horizon and coordinate length. Unknown catalog names raise `ValidationError`.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_families_state.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `variation_of_constants_prefix`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.variation_of_constants_prefix`. Reflected implementation `komorebi_math.coordinates.recurrence.variation_of_constants_prefix`. The same runtime object is also available through `komorebi_math.variation_of_constants_prefix`. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-RECURRENCE-DEFECT`.

Manifest signature (`s`).

```
(record: 'RecurrenceCoordinateRecord') -> 'Vector'
```

Definition. Reconstruct a prefix through the companion Green-kernel formula.

Contract (`D, C, H, R, X`). Recurrence coefficients are exact and must define positive order. A sequence prefix must contain at least the initial state when analysis or synthesis needs it. Transform dimensions are tied to the requested finite length, and all defect, Green-kernel, and reconstruction routines reject inconsistent orders or horizons.

Guarantees (`E, P, B, K`). Arithmetic is exact over integers and rational `Fraction` values. Certificates cover the stated finite identity, rank, reconstruction, or invariance claim only. Dense elimination and inversion can require cubic arithmetic-operation cost and quadratic storage, while exact numerator and denominator sizes may grow. Declared coordinate budgets bound supported dimensions and horizons where the interface exposes them.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_recurrence.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 16, 20, and 21.

C.2C · `walsh_hadamard_transform`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.coordinates.walsh_hadamard_transform`. Reflected implementation `komorebi_math.coordinates.numeric.walsh_hadamard_transform`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.coordinates` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C2-NUMERIC-TRANSFORM`.

Manifest signature (s).

```
(size: 'int', *, orthonormal: 'bool' = True, tolerance: 'float' = 1e-12) -> 'NumericCoordinateTransform'
```

Definition. Compute the Sylvester Walsh-Hadamard transform for a power-of-two size.

Contract (D, C, H, R, X). The transform matrix must be finite, two-dimensional, and square when inversion is requested. Application and composition check dimensions and labels. Named Fourier, cosine, Walsh, Haar, and modal constructors enforce their size, rank, and diagonalizability conditions.

Guarantees (E, P, B, K). These paths use finite NumPy linear algebra and report tolerance-qualified numerical evidence rather than exact equality. Dense matrices use quadratic storage and common decompositions require cubic floating-point work. Optional accelerator behavior is not implied by this interface.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. `tests/test_coordinates_general_numeric_packet.py` and the independent verifier for coordinate systems cover the applicable construction, roundtrip, rank, failure, persistence, or resource behavior. The source validator for coordinate systems checks the exact signature, implementation identity, domain facade, aliases, regression coverage, and unique anchor. See Chapters 15, 28, and 32.

C.3 `komorebi_math.generating`: 181 entries

C.3A Foundational normalized generating functions: 80 entries

This generating-namespace section records the exact finite calculus that the later Mahler, Cartier, congruence, and prime power compilers use. It begins with resource limits and coefficient domains, then documents normalized bases, formal series, custom function builders, named sequences, bounded relation inference, residue sections, monoid indexed products, FIR conversion, and portable snapshots. These contracts remain in the research tier unless a card lists an existing stable facade.

Contract family	Cards
Resource budgets	2
Exact coefficient domains	9
Normalized bases	13
Formal series	2
Finite series over explicit domains	2
Custom generating functions	11
Named exact sequences	12
Bounded relation inference	12
Residue sections and root filters	5
Series over finite monoids	5
FIR adapters	4
Portable generating records	3
Total	**80**

The distinction between exact formal algebra and finite numerical adaptation is explicit. Domain, basis, series, sequence, and closed form records use exact integer or rational arithmetic unless a finite residue domain is selected. Root filters and FIR responses cross into floating point evaluation and therefore state residual or tolerance qualified guarantees. Relation guessers are bounded prefix inference tools. A returned relation is not presented as an infinite sequence theorem without separate proof.

C.3A · AlgebraicGFGuess

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.AlgebraicGFGuess`. Reflected implementation `komorebi_math.generating.closed_forms.AlgebraicGFGuess`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(x_degree: 'int', y_degree: 'int', monomials: 'tuple[tuple[int, int, int], ...]', fit_coefficients: 'int',
   ↪ holdout_coefficients: 'int', exact_on_prefix: 'bool') -> None
```

Definition. Bounded algebraic relation candidate for an ordinary series.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend. The principal public operations are `expression`.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · BasisCertificate

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.BasisCertificate`. Reflected implementation `komorebi_math.generating.basis.BasisCertificate`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(name: 'str', degree: 'int', nonzero_normalization: 'bool', integral_structure_constants: 'bool',
   ↪ maximum_denominator: 'int', maximum_numerator_bits: 'int') -> None
```

Definition. Finite exact diagnostics for one normalized monomial basis.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · BasisDescriptor

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.BasisDescriptor`. Reflected implementation `komorebi_math.generating.basis.BasisDescriptor`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(name: 'str', kind: 'str', parameters: 'tuple[tuple[str, BasisParameter], ...]' = ()) -> None
```

Definition. Declarative, portable description of one normalized monomial basis.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor. The principal public operations are `create`, `parameter_map`.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · CoefficientDomain

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.CoefficientDomain`. Reflected implementation `komorebi_math.generating.domains.CoefficientDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Protocol for exact coefficient arithmetic and safe serialization.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas. The principal public operations are `coerce`, `add`, `subtract`, `multiply`, `inverse`, `is_unit`, `equal`, `encode`, `decode`, `descriptor`.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · CustomFunctionSpec

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.CustomFunctionSpec`. Reflected implementation `komorebi_math.generating.functions.CustomFunctionSpec`. The same runtime object is also exported as `komorebi_math.CustomFunctionSpec`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', basis: 'WeightedMonomialBasis', builder: 'CoefficientBuilder', source_kind: 'str' = 'custom',
    ↪ metadata: 'Mapping[str, object]' = <factory>) -> None
```

Definition. A named exact coefficient source with an explicit basis and metadata.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names. The principal public operations are `series`.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · DEFAULT_GENERATING_BUDGET

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.DEFAULT_GENERATING_BUDGET`. Reflected implementation `komorebi_math.generating.budget.GeneratingBudget`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `data`. Profile `C3-FOUND-BUDGET`.

Manifest signature (s).

```
null
```

Definition. The immutable default resource budget used by generating operations that receive no explicit budget.

Contract (D, C, H, R, X). Every stored limit must be a positive integer. Degree, term, matrix, state, modulus, serialized size, and coefficient bit checks reject malformed requests before the corresponding expansion or allocation begins. The default object is immutable. Exceeding a declared limit raises `ResourceLimitError`, while malformed values raise `ValidationError`.

Guarantees (E, P, B, K). The budget performs deterministic scalar validation and does not estimate hidden backend memory. Its checks are constant time. A caller who supplies a larger budget accepts the resulting exact arithmetic, state enumeration, and serialization costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_domains.py` and `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 64.

C.3A · FIRSeriesAdapter

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.FIRSeriesAdapter`. Reflected implementation `komorebi_math.generating.adapters.FIRSeriesAdapter`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-ADAPTER`.

Manifest signature (s).

```
(series: 'FormalSeries', taps: 'np.ndarray', variable_substitution: 'str' = 'formal z maps to delay z^(-1)') ->
    ↪ None
```

Definition. A finite transfer polynomial interpreted under `z -> z**(-1)`.

Contract (D, C, H, R, X). FIR inputs must be a nonempty one dimensional finite real array. Conversion to `FormalSeries` rationalizes taps, optionally limiting denominators. Conversion from a series validates the requested degree and numeric dtype. An adapter requires one tap per stored ordinary coefficient. Frequency responses validate finite sampling parameters and certificates compare the declared coefficient to tap conversion. The principal public operations are `certificate`, `response`.

Guarantees (E, P, B, K). The formal side is exact before conversion to NumPy. Tap arrays and frequency responses use floating point arithmetic, and their certificates are qualified by a stated tolerance. Conversion is linear in the number of taps. Frequency response evaluation delegates to the signal implementation and scales with the chosen point count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 31, and 66.

C.3A · FiniteMonoidSeries

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.FiniteMonoidSeries`. Reflected implementation `komorebi_math.generating.monoid.FiniteMonoidSeries`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-MONOID`.

Manifest signature (s).

```
(coefficients: 'Mapping[Index, Fraction]', combine: 'Callable[[Index, Index], Index]', identity: 'Index', name:
    ↪ 'str' = 'monoid series') -> None
```

Definition. A finite coefficient map with a declared associative index product.

Contract (D, C, H, R, X). A finite monoid series stores a finite coefficient map, an index combination rule, an identity, and a name. Multiplication requires the same identity and combines only represented pairs, optionally filtered by an admissibility predicate. Additive series use nonnegative indices. Multiplicative series use positive integer indices. Dirichlet convolution validates a nonnegative count, and valuation packets require a prime of at least two. The principal public operations are `coefficient`, `multiply`.

Guarantees (E, P, B, K). Coefficient arithmetic is exact over `Fraction`. The class assumes that the index operation supplied by the caller is associative and does not prove that law. Dense finite multiplication is quadratic in the number of stored indices. Dirichlet convolution uses direct divisor enumeration for the requested prefix.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 24, and 25.

C.3A · FiniteNormalizedSeries

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.FiniteNormalizedSeries`. Reflected implementation `komorebi_math.generating.finite_series.FiniteNormalizedSeries`. The same runtime object is also exported as `komorebi_math.FiniteNormalizedSeries`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN-SERIES`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', domain: 'CoefficientDomain[Any]', coefficients: 'Iterable[Any]', *, budget:
    ↪ 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000,
    ↪ maximum_matrix_dimension=4096, maximum_reachable_states=100000, maximum_local_combinations=1000000,
    ↪ maximum_modulus=2000000, maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'None'
```

Definition. A finite exact series `sum a_n z^n/gamma_n` over one domain.

Contract (D, C, H, R, X). The basis, coefficient domain, and budget must satisfy their public protocols. Coefficients are coerced into the declared domain. Binary operations require matching domains and compatible bases. Reciprocal requires a unit constant coefficient. Composition, exponential, and logarithm impose the same constant term conditions as ordinary formal calculus. Conversion returns an explicit finite transfer certificate. The principal public operations are `add`, `subtract`, `multiply`, `reciprocal`, `compose`, `exp`, `log`, `project`, `convert`, `certificate`.

Guarantees (E, P, B, K). Results are exact in the selected coefficient domain and bounded by the supplied `Generating Budget`. A valid transfer certificate checks reconstruction coefficient by coefficient through the stored degree. Complexity follows finite polynomial arithmetic, with quadratic convolution and potentially cubic composition at the truncation boundary.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 61.

C.3A · FormalSeries

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.FormalSeries`. Reflected implementation `komorebi_math.generating.series.FormalSeries`. The same runtime object is also exported as `komorebi_math.FormalSeries`, `komorebi_math.stable.FormalSeries`, `komorebi_math.v1.FormalSeries`, `komorebi_math.api.v1.FormalSeries`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. The stable and versioned aliases keep their separate frozen compatibility commitment. Manifest kind `class`. Profile `C3-FOUND-SERIES`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', coefficients: 'Iterable[int | Fraction]') -> 'None'
```

Definition. A finite exact series `sum a_n z^n/gamma_n`.

Contract (D, C, H, R, X). The coefficient tuple is finite and nonempty. Binary operations require compatible basis semantics or an explicit conversion. Reciprocal requires a nonzero constant term. Composition requires an inner zero constant term. Formal exponential requires zero constant term, while formal logarithm requires constant term one. Projectors and packets validate modulus and residue addresses. The principal public operations are `add`, `subtract`, `multiply`, `reciprocal`, `compose`, `exp`, `log`, `project`, `packet`, `convert`, `evaluate`.

Guarantees (E, P, B, K). Every algebraic result is exact over rational coefficients at the requested finite truncation. Multiplication, composition, reciprocal, exponential, and logarithm are finite formal operations and do not assert analytic convergence. Naive multiplication is quadratic in truncation degree, while composition and repeated powers can require cubic work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foun-

dations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · FrozenGeneratingFunction

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.FrozenGeneratingFunction`. Reflected implementation `komorebi_math.generating.portable.FrozenGeneratingFunction`. The same runtime object is also exported as `komorebi_math.FrozenGeneratingFunction`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-PORTABLE`.

Manifest signature (s).

```
(name: 'str', basis_name: 'str', normalization: 'tuple[Fraction, ...]', coefficients: 'tuple[Fraction, ...]',
   ↪ source_kind: 'str', metadata: 'Mapping[str, Any]' = <factory>) -> None
```

Definition. Provider-independent finite snapshot of a custom generating function.

Contract (D, C, H, R, X). A frozen function requires nonempty names, a nonempty coefficient prefix, normalization of equal length beginning with one, no zero normalization values, and portable metadata. Reconstruction cannot exceed the captured degree. Freezing accepts only `CustomFunctionSpec`. Codec registration installs closed data only decoders and does not permit arbitrary Python object construction. The principal public operations are `degree`, `series`.

Guarantees (E, P, B, K). The frozen record preserves exact rational coefficients and basis normalization independently of the original callback. Roundtrip integrity is delegated to the project portable envelope and its digest checks. Serialization cost is linear in the captured prefix, subject to the global payload budget used by the persistence layer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 61, and 72.

C.3A · FunctionRegistry

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.FunctionRegistry`. Reflected implementation `komorebi_math.generating.functions.FunctionRegistry`. The same runtime object is also exported as `komorebi_math.FunctionRegistry`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
() -> 'None'
```

Definition. An explicit custom-function registry. Names cannot silently overwrite existing entries.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names. The principal public operations are `register`, `get`, `names`.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · GeneratingBudget

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.GeneratingBudget`. Reflected implementation `komorebi_math.generating.budget.GeneratingBudget`. The same runtime object is also exported as `komorebi_math.GeneratingBudget`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-BUDGET`.

Manifest signature (s).

```
(maximum_degree: 'int' = 100000, maximum_coefficient_bits: 'int' = 4000000, maximum_matrix_dimension: 'int' = 4096,
    ↪ maximum_reachable_states: 'int' = 100000, maximum_local_combinations: 'int' = 1000000, maximum_modulus:
    ↪ 'int' = 2000000, maximum_serialized_bytes: 'int' = 67108864, maximum_recursion_depth: 'int' = 1000) -> None
```

Definition. Upper bounds checked before potentially expensive operations.

Contract (D, C, H, R, X). Every stored limit must be a positive integer. Degree, term, matrix, state, modulus, serialized size, and coefficient bit checks reject malformed requests before the corresponding expansion or allocation begins. The default object is immutable. Exceeding a declared limit raises `ResourceLimitError`, while malformed values raise `ValidationError`. The principal public operations are `require_degree`, `require_terms`, `require_matrix_dimension`, `require_states`, `require_local_combinations`, `require_modulus`, `require_serialized_bytes`, `require_coefficient_bits`.

Guarantees (E, P, B, K). The budget performs deterministic scalar validation and does not estimate hidden backend memory. Its checks are constant time. A caller who supplies a larger budget accepts the resulting exact arithmetic, state enumeration, and serialization costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_domains.py` and `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 64.

C.3A · HypergeometricGuess

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.HypergeometricGuess`. Reflected implementation `komorebi_math.generating.closed_forms.HypergeometricGuess`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(numerator: 'tuple[int, ...]', denominator: 'tuple[int, ...]', fit_relations: 'int', holdout_relations: 'int',
    ↪ exact_on_prefix: 'bool') -> None
```

Definition. Bounded rational candidate for a consecutive-term ratio.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend. The principal public operations are `ratio_expression`.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · INTEGER_DOMAIN

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.INTEGER_DOMAIN`. Reflected implementation `komorebi_math.generating.domains.IntegerDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `data`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
null
```

Definition. The shared exact integer coefficient domain instance.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · IntegerDomain

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.IntegerDomain`. Reflected implementation `komorebi_math.generating.domains.IntegerDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(name: 'str' = 'integers', zero: 'int' = 0, one: 'int' = 1) -> None
```

Definition. The exact integer coefficient domain.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas. The principal public operations are `coerce`, `add`, `subtract`, `multiply`, `inverse`, `is_unit`, `encode`, `decode`, `descriptor`.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · LinearRecurrenceGuess

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.LinearRecurrenceGuess`. Reflected implementation `komorebi_math.generating.closed_forms.LinearRecurrenceGuess`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(order: 'int', coefficients: 'tuple[Fraction, ...]', fit_terms: 'int', holdout_terms: 'int', exact_on_prefix:
   ↪  'bool') -> None
```

Definition. Bounded exact candidate for a constant-coefficient recurrence.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend. The principal public operations are `equation`.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · NormalizedBasis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.NormalizedBasis`. Reflected implementation `komorebi_math.generating.basis.WeightedMonomialBasis`. The same runtime object is also exported as `komorebi_math.NormalizedBasis`. Within that namespace, `komorebi_math.generating.NormalizedMonomialBasis` and `komorebi_math.generating.WeightedMonomialBasis` resolve to the same runtime object. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(name: 'str', gamma: 'GammaRule', *, descriptor: 'BasisDescriptor | None' = None) -> 'None'
```

Definition. A basis `e_n(z)=z^n/gamma_n` with `gamma_0=1`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor. The principal public operations are `gamma`, `lowering_weight`, `structure_constant`, `packet_transfer_weight`, `finite_certificate`, `require_descriptor`.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · NormalizedMonomialBasis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.NormalizedMonomialBasis`. Reflected implementation `komorebi_math.generating.basis.WeightedMonomialBasis`. In the reference manifest, this symbol is exported only from the generating namespace. Within that namespace, `komorebi_math.generating.NormalizedBasis` and `komorebi_math.generating.WeightedMonomialBasis` resolve to the same runtime object. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(name: 'str', gamma: 'GammaRule', *, descriptor: 'BasisDescriptor | None' = None) -> 'None'
```

Definition. A basis `e_n(z)=z^n/gamma_n` with `gamma_0=1`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor. The principal public operations are `gamma`, `lowering_weight`, `structure_constant`, `packet_transfer_weight`, `finite_certificate`, `require_descriptor`.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · PRecursiveGuess

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PRecursiveGuess`. Reflected implementation `komorebi_math.generating.closed_forms.PRecursiveGuess`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(order: 'int', degree: 'int', polynomials: 'tuple[tuple[int, ...], ...]', fit_relations: 'int', holdout_relations:
    ↪ 'int', exact_on_prefix: 'bool') -> None
```

Definition. Bounded polynomial-coefficient recurrence candidate.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend. The principal public operations are `expression`.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · PacketIdentity

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PacketIdentity`. Reflected implementation `komorebi_math.generating.series.PacketIdentity`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-SERIES`.

Manifest signature (s).

```
(modulus: 'int', residue: 'int', source_basis: 'str', target_basis: 'str', source_degree: 'int', packet_degree:
   ↪  'int', valid: 'bool') -> None
```

Definition. Exact finite identity for one residue packet transfer.

Contract (D, C, H, R, X). The coefficient tuple is finite and nonempty. Binary operations require compatible basis semantics or an explicit conversion. Reciprocal requires a nonzero constant term. Composition requires an inner zero constant term. Formal exponential requires zero constant term, while formal logarithm requires constant term one. Projectors and packets validate modulus and residue addresses.

Guarantees (E, P, B, K). Every algebraic result is exact over rational coefficients at the requested finite truncation. Multiplication, composition, reciprocal, exponential, and logarithm are finite formal operations and do not assert analytic convergence. Naive multiplication is quadratic in truncation degree, while composition and repeated powers can require cubic work.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · PrimeFieldDomain

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PrimeFieldDomain`. Reflected implementation `komorebi_math.generating.domains.PrimeFieldDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(modulus: 'int', name: 'str' = 'prime_field') -> None
```

Definition. The prime field `F_p` represented by canonical integer residues.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas. The principal public operations are `coerce`, `add`, `subtract`, `multiply`, `inverse`, `is_unit`, `encode`, `decode`, `descriptor`.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · QuasiPolynomialGuess

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.QuasiPolynomialGuess`. Reflected implementation `komorebi_math.generating.closed_forms.QuasiPolynomialGuess`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(period: 'int', degree: 'int', residue_values: 'tuple[tuple[Fraction, ...], ...]', fit_terms: 'int',
   ↪ holdout_terms: 'int', exact_on_prefix: 'bool') -> None
```

Definition. Bounded residue-class polynomial candidate.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · RATIONAL_DOMAIN

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.RATIONAL_DOMAIN`. Reflected implementation `komorebi_math.generating.domains.RationalDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `data`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
null
```

Definition. The shared exact rational coefficient domain instance.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · RationalDomain

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.RationalDomain`. Reflected implementation `komorebi_math.generating.domains.RationalDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(name: 'str' = 'rationals', zero: 'Fraction' = Fraction(0, 1), one: 'Fraction' = Fraction(1, 1)) -> None
```

Definition. The exact rational coefficient field.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas. The principal public operations are `coerce`, `add`, `subtract`, `multiply`, `inverse`, `is_unit`, `encode`, `decode`, `descriptor`.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · ResidueRingDomain

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.ResidueRingDomain`. Reflected implementation `komorebi_math.generating.domains.ResidueRingDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(modulus: 'int', name: 'str' = 'residue_ring') -> None
```

Definition. Exact arithmetic in the finite ring `Z / modulus Z`.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas. The principal public operations are `coerce`, `add`, `subtract`, `multiply`, `inverse`, `is_unit`, `encode`, `decode`, `descriptor`.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · SectionCycleAudit

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.SectionCycleAudit`. Reflected implementation `komorebi_math.generating.sections.SectionCycleAudit`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-SECTION`.

Manifest signature (s).

```
(basis: 'str', modulus: 'int', degree: 'int', signed: 'bool', one_step_failures: 'int', full_cycle_failures:
   ↪  'int', root_filter_residual: 'float') -> None
```

Definition. Finite lowering-cycle and root-filter audit summary.

Contract (D, C, H, R, X). The truncation degree must be nonnegative. A section requires a positive modulus and a residue in range. The signed option changes the lowering cycle convention but not the address rules. The audit compares one step, a full cycle, and a finite complex root filter at the supplied evaluation point.

Guarantees (E, P, B, K). Series coefficients and lowering operations are exact. The root filter is a finite floating point evaluation and is reported through a residual rather than exact equality. Construction is linear in the truncation degree, while an audit over all residue classes scales with both degree and modulus.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 25.

C.3A · SeriesTransferCertificate

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.SeriesTransferCertificate`. Reflected implementation `komorebi_math.generating.finite_series.SeriesTransferCertificate`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN-SERIES`.

Manifest signature (s).

```
(valid: 'bool', degree: 'int', source_basis: 'str', target_basis: 'str', domain: 'str', failures: 'tuple[int,
   ↪  ...]' = ()) -> None
```

Definition. Exact finite certificate for a normalized basis transfer.

Contract (D, C, H, R, X). The basis, coefficient domain, and budget must satisfy their public protocols. Coefficients are coerced into the declared domain. Binary operations require matching domains and compatible bases. Reciprocal requires a unit constant coefficient. Composition, exponential, and logarithm impose the same constant term conditions as ordinary formal calculus. Conversion returns an explicit finite transfer certificate. The principal public operations are `certificate`, `require`.

Guarantees (E, P, B, K). Results are exact in the selected coefficient domain and bounded by the supplied `Generating Budget`. A valid transfer certificate checks reconstruction coefficient by coefficient through the stored degree. Complexity follows finite polynomial arithmetic, with quadratic convolution and potentially cubic composition at the truncation boundary.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 61.

C.3A · TruncatedPadicDomain

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.TruncatedPadicDomain`. Reflected implementation `komorebi_math.generating.domains.TruncatedPadicDomain`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(prime: 'int', precision: 'int') -> 'None'
```

Definition. The finite ring `Z / p^r Z` with declared prime and precision.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas. The principal public operations are `coerce`, `add`, `subtract`, `multiply`, `inverse`, `valuation`, `encode`, `decode`, `descriptor`.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · WeightedMonomialBasis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.WeightedMonomialBasis`. Reflected implementation `komorebi_math.generating.basis.WeightedMonomialBasis`. The same runtime object is also exported as `komorebi_math.WeightedMonomialBasis`. Within that namespace, `komorebi_math.generating.NormalizedBasis` and `komorebi_math.generating.NormalizedMonomialBasis` resolve to the same runtime object. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(name: 'str', gamma: 'GammaRule', *, descriptor: 'BasisDescriptor | None' = None) -> 'None'
```

Definition. A basis `e_n(z)=z^n/gamma_n` with `gamma_0=1`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor. The principal public operations are `gamma`, `lowering_weight`, `structure_constant`, `packet_transfer_weight`, `finite_certificate`, `require_descriptor`.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · additive_series

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.additive_series`. Reflected implementation `komorebi_math.generating.monoid.additive_series`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-MONOID`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]') -> 'FiniteMonoidSeries[int]'
```

Definition. Create a finite ordinary series whose index operation is addition.

Contract (D, C, H, R, X). A finite monoid series stores a finite coefficient map, an index combination rule, an identity, and a name. Multiplication requires the same identity and combines only represented pairs, optionally filtered by an admissibility predicate. Additive series use nonnegative indices. Multiplicative series use positive integer indices. Dirichlet convolution validates a nonnegative count, and valuation packets require a prime of at least two.

Guarantees (E, P, B, K). Coefficient arithmetic is exact over `Fraction`. The class assumes that the index operation supplied by the caller is associative and does not prove that law. Dense finite multiplication is quadratic in the number of stored indices. Dirichlet convolution uses direct divisor enumeration for the requested prefix.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 24, and 25.

C.3A · algebraic_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.algebraic_function`. Reflected implementation `komorebi_math.generating.functions.algebraic_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', polynomial_terms: 'Mapping[tuple[int, int], int | Fraction]', initial_value: 'int | Fraction', *,
    ↪ basis: 'WeightedMonomialBasis | None' = None) -> 'CustomFunctionSpec'
```

Definition. Create the unique formal branch of `P(z,y)=0` at `y(0)=y0`.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · apery_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.apery_numbers`. Reflected implementation `komorebi_math.generating.sequences.apery_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return the Apéry numbers for zeta(3) by their finite binomial sum.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · audit_section_cycle

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_section_cycle`. Reflected implementation `komorebi_math.generating.sections.audit_section_cycle`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SECTION`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', *, modulus: 'int', degree: 'int', signed: 'bool' = False, z: 'complex' =
   ↪  (0.37+0.11j)) -> 'SectionCycleAudit'
```

Definition. Audit lowering cycles and root-filter projection on finite truncations.

Contract (D, C, H, R, X). The truncation degree must be nonnegative. A section requires a positive modulus and a residue in range. The signed option changes the lowering cycle convention but not the address rules. The audit compares one step, a full cycle, and a finite complex root filter at the supplied evaluation point.

Guarantees (E, P, B, K). Series coefficients and lowering operations are exact. The root filter is a finite floating point evaluation and is reported through a residual rather than exact equality. Construction is linear in the truncation degree, while an audit over all residue classes scales with both degree and modulus.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 25.

C.3A · basis_from_descriptor

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.basis_from_descriptor`. Reflected implementation `komorebi_math.generating.basis.basis_from_descriptor`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(descriptor: 'BasisDescriptor') -> 'WeightedMonomialBasis'
```

Definition. Rebuild a basis from the closed declarative descriptor registry.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · basis_from_values

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.basis_from_values`. Reflected implementation `komorebi_math.generating.basis.basis_from_values`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(name: 'str', values: 'Iterable[int | Fraction]') -> 'WeightedMonomialBasis'
```

Definition. Create a finite portable basis from an explicit normalization table.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · bell_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.bell_numbers`. Reflected implementation `komorebi_math.generating.sequences.bell_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return the first `count` ordinary Bell numbers by their recurrence.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · bernoulli_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.bernoulli_numbers`. Reflected implementation `komorebi_math.generating.sequences.bernoulli_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[Fraction, ...]'
```

Definition. Return Bernoulli numbers with `B_1=-1/2`.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_arithmetic_euler.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · catalan_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.catalan_numbers`. Reflected implementation `komorebi_math.generating.sequences.catalan_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return the first `count` Catalan numbers.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · central_binomial_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.central_binomial_numbers`. Reflected implementation `komorebi_math.generating.sequences.central_binomial_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return `binomial(2*n, n)` for `0 <= n < count`.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · characteristic_closed_form

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.characteristic_closed_form`. Reflected implementation `komorebi_math.generating.closed_forms.characteristic_closed_form`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(recurrence: 'LinearRecurrenceGuess', initial: 'Sequence[int | Fraction]') -> 'Any | None'
```

Definition. Ask SymPy for a symbolic closed form of a constant recurrence.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · compose_functions

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.compose_functions`. Reflected implementation `komorebi_math.generating.functions.compose_functions`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', outer: 'CustomFunctionSpec', inner: 'CustomFunctionSpec') -> 'CustomFunctionSpec'
```

Definition. Create an exact ordinary-composition specification.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · custom_exponential

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.custom_exponential`. Reflected implementation `komorebi_math.generating.sections.custom_exponential`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SECTION`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', degree: 'int') -> 'FormalSeries'
```

Definition. Return `E_gamma(z)=sum z^n/gamma_n` through one degree.

Contract (D, C, H, R, X). The truncation degree must be nonnegative. A section requires a positive modulus and a residue in range. The signed option changes the lowering cycle convention but not the address rules. The audit compares one step, a full cycle, and a finite complex root filter at the supplied evaluation point.

Guarantees (E, P, B, K). Series coefficients and lowering operations are exact. The root filter is a finite floating point evaluation and is reported through a residual rather than exact equality. Construction is linear in the truncation degree, while an audit over all residue classes scales with both degree and modulus.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 25.

C.3A · custom_section

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.custom_section`. Reflected implementation `komorebi_math.generating.sections.custom_section`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SECTION`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', modulus: 'int', residue: 'int', degree: 'int', *, signed: 'bool' = False) ->
    ↪ 'FormalSeries'
```

Definition. Return one residue section of the custom exponential.

Contract (D, C, H, R, X). The truncation degree must be nonnegative. A section requires a positive modulus and a residue in range. The signed option changes the lowering cycle convention but not the address rules. The audit compares one step, a full cycle, and a finite complex root filter at the supplied evaluation point.

Guarantees (E, P, B, K). Series coefficients and lowering operations are exact. The root filter is a finite floating point evaluation and is reported through a residual rather than exact equality. Construction is linear in the truncation degree, while an audit over all residue classes scales with both degree and modulus.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 25.

C.3A · dirichlet_convolution

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.dirichlet_convolution`. Reflected implementation `komorebi_math.generating.monoid.dirichlet_convolution`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-MONOID`.

Manifest signature (s).

```
(left: 'Iterable[int | Fraction]', right: 'Iterable[int | Fraction]', *, count: 'int') -> 'tuple[Fraction, ...]'
```

Definition. Return `(a*b)(n)=sum_(d|n)a(d)b(n/d)` for `1 <= n <= count`.

Contract (D, C, H, R, X). A finite monoid series stores a finite coefficient map, an index combination rule, an identity, and a name. Multiplication requires the same identity and combines only represented pairs, optionally filtered by an admissibility predicate. Additive series use nonnegative indices. Multiplicative series use positive integer indices. Dirichlet convolution validates a nonnegative count, and valuation packets require a prime of at least two.

Guarantees (E, P, B, K). Coefficient arithmetic is exact over `Fraction`. The class assumes that the index operation supplied by the caller is associative and does not prove that law. Dense finite multiplication is quadratic in the number of stored indices. Dirichlet convolution uses direct divisor enumeration for the requested prefix.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 24, and 25.

C.3A · domain_from_descriptor

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.domain_from_descriptor`. Reflected implementation `komorebi_math.generating.domains.domain_from_descriptor`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-DOMAIN`.

Manifest signature (s).

```
(payload: 'Any') -> 'CoefficientDomain[Any]'
```

Definition. Construct one supported exact domain from a data-only descriptor.

Contract (D, C, H, R, X). A coefficient domain supplies coercion, exact arithmetic, unit tests, inversion, equality, portable encoding, decoding, and a descriptor containing only data. Integer inversion is restricted to `1` and `-1`. Residue ring inversion requires a unit. Prime fields require a prime modulus. Truncated p-adic domains require a prime and positive precision. Descriptor reconstruction accepts only the closed supported schemas.

Guarantees (E, P, B, K). All arithmetic is exact in the declared finite or rational domain. Encodings are canonical for the represented element. Prime validation is deterministic for the supplied modulus. Operations are constant time in the number of coefficients, although integer bit complexity grows with operand size.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 23, and 61.

C.3A · euler_product_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.euler_product_function`. Reflected implementation `komorebi_math.generating.functions.euler_product_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', exponents: 'Mapping[int, int | Fraction] | Callable[[int], int | Fraction]', *, basis:
    ↪ 'WeightedMonomialBasis | None' = None) -> 'CustomFunctionSpec'
```

Definition. Create `prod_(m>=1) (1-z^m)^(-c_m)` by log-derivative recurrence.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · explicit_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.explicit_function`. Reflected implementation `komorebi_math.generating.functions.explicit_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', basis: 'WeightedMonomialBasis', coefficients: 'tuple[int | Fraction, ...]') -> 'CustomFunctionSpec'
```

Definition. Create a finite exact coefficient source in a declared normalized basis.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · exponential_basis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.exponential_basis`. Reflected implementation `komorebi_math.generating.basis.exponential_basis`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(*, name: 'str' = 'exponential') -> 'WeightedMonomialBasis'
```

Definition. Return the exponential generating-function basis `z^n/n!`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py`, `tests/test_generating_domains.py`, and `tests/test_coordinates_normalized_persistence.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · factorial_power_basis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.factorial_power_basis`. Reflected implementation `komorebi_math.generating.basis.factorial_power_basis`. The same runtime object is also exported as `komorebi_math.factorial_power_basis`, `komorebi_math.stable.factorial_power_basis`, `komorebi_math.v1.factorial_power_basis`, `komorebi_math.api.v1.factorial_power_basis`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. The stable and versioned aliases keep their separate frozen compatibility commitment. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(power: 'int', *, name: 'str | None' = None) -> 'WeightedMonomialBasis'
```

Definition. Return `z^n/(n!)^power` for a positive integer power.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · factorial_power_bell_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.factorial_power_bell_function`. Reflected implementation `komorebi_math.generating.functions.factorial_power_bell_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(power: 'int', *, name: 'str | None' = None) -> 'CustomFunctionSpec'
```

Definition. Create the unweighted factorial-power Bell family of a positive order.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · fibonacci_factorial_basis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.fibonacci_factorial_basis`. Reflected implementation `komorebi_math.generating.basis.fibonacci_factorial_basis`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(*, name: 'str' = 'fibonacci-factorial') -> 'WeightedMonomialBasis'
```

Definition. Return the fibonomial basis with `gamma_n=prod_(j=1)^n F_j`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py`, `tests/test_generating_domains.py`, and `tests/test_coordinates_normalized_persistence.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · fibonacci_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.fibonacci_numbers`. Reflected implementation `komorebi_math.generating.sequences.fibonacci_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return the first `count` Fibonacci numbers beginning with zero.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · fir_taps_to_series

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.fir_taps_to_series`. Reflected implementation `komorebi_math.generating.adapters.fir_taps_to_series`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-ADAPTER`.

Manifest signature (s).

```
(taps: 'Any', *, basis: 'WeightedMonomialBasis | None' = None, max_denominator: 'int | None' = None) ->
    ↪ 'FormalSeries'
```

Definition. Convert a finite real FIR tap vector into an exact formal series.

Contract (D, C, H, R, X). FIR inputs must be a nonempty one dimensional finite real array. Conversion to `FormalSeries` rationalizes taps, optionally limiting denominators. Conversion from a series validates the requested degree and numeric dtype. An adapter requires one tap per stored ordinary coefficient. Frequency responses validate finite sampling parameters and certificates compare the declared coefficient to tap conversion.

Guarantees (E, P, B, K). The formal side is exact before conversion to NumPy. Tap arrays and frequency responses use floating point arithmetic, and their certificates are qualified by a stated tolerance. Conversion is linear in the number of taps. Frequency response evaluation delegates to the signal implementation and scales with the chosen point count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 31, and 66.

C.3A · freeze_custom_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.freeze_custom_function`. Reflected implementation `komorebi_math.generating.portable.freeze_custom_function`. The same runtime object is also exported as `komorebi_math.freeze_custom_function`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-PORTABLE`.

Manifest signature (s).

```
(function: 'CustomFunctionSpec', degree: 'int', *, include_metadata: 'bool' = True) -> 'FrozenGeneratingFunction'
```

Definition. Capture one custom function into a finite provider-independent record.

Contract (D, C, H, R, X). A frozen function requires nonempty names, a nonempty coefficient prefix, normalization of equal length beginning with one, no zero normalization values, and portable metadata. Reconstruction cannot exceed the captured degree. Freezing accepts only `CustomFunctionSpec`. Codec registration installs closed data only decoders and does not permit arbitrary Python object construction.

Guarantees (E, P, B, K). The frozen record preserves exact rational coefficients and basis normalization independently of the original callback. Roundtrip integrity is delegated to the project portable envelope and its digest checks. Serialization cost is linear in the captured prefix, subject to the global payload budget used by the persistence layer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 61, and 72.

C.3A · generalized_bell_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.generalized_bell_numbers`. Reflected implementation `komorebi_math.generating.sequences.generalized_bell_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(power: 'int', count: 'int') -> 'tuple[int, ...]'
```

Definition. Return the factorial-power Bell family.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · generalized_bell_polynomials

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.generalized_bell_polynomials`. Reflected implementation `komorebi_math.generating.sequences.generalized_bell_polynomials`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(power: 'int', count: 'int') -> 'tuple[tuple[int, ...], ...]'
```

Definition. Return coefficient rows of factorial-power Bell polynomials.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · guess_algebraic_gf

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.guess_algebraic_gf`. Reflected implementation `komorebi_math.generating.closed_forms.guess_algebraic_gf`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]', *, max_x_degree: 'int' = 4, max_y_degree: 'int' = 4, holdout: 'int | None' =
    ↪ None) -> 'AlgebraicGFGuess | None'
```

Definition. Guess an exact relation `P(x,F(x))=0` from ordinary coefficients.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · guess_hypergeometric_ratio

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.guess_hypergeometric_ratio`. Reflected implementation `komorebi_math.generating.closed_forms.guess_hypergeometric_ratio`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]', *, max_numerator_degree: 'int' = 4, max_denominator_degree: 'int' = 4,
   ↪ holdout: 'int | None' = None) -> 'HypergeometricGuess | None'
```

Definition. Guess `a[n+1]/a[n]=P(n)/Q(n)` by exact nullspace search.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · guess_linear_recurrence

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.guess_linear_recurrence`. Reflected implementation `komorebi_math.generating.closed_forms.guess_linear_recurrence`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]', *, max_order: 'int' = 12, holdout: 'int | None' = None) ->
   ↪ 'LinearRecurrenceGuess | None'
```

Definition. Guess the smallest exact constant-coefficient recurrence.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · guess_p_recursive

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.guess_p_recursive`. Reflected implementation `komorebi_math.generating.closed_forms.guess_p_recursive`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]', *, max_order: 'int' = 4, max_degree: 'int' = 5, holdout: 'int | None' = None)
   ↪  -> 'PRecursiveGuess | None'
```

Definition. Guess `sum_(j=0)^r P_j(n)a[n+j]=0` exactly on a prefix.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · guess_quasipolynomial

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.guess_quasipolynomial`. Reflected implementation `komorebi_math.generating.closed_forms.guess_quasipolynomial`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]', *, max_period: 'int' = 12, max_degree: 'int' = 6, holdout: 'int | None' =
   ↪  None) -> 'QuasiPolynomialGuess | None'
```

Definition. Guess a quasipolynomial by constant finite differences on each lane.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · hypergeometric_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.hypergeometric_function`. Reflected implementation `komorebi_math.generating.functions.hypergeometric_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', initial: 'int | Fraction', ratio: 'Callable[[int], int | Fraction]', *, basis:
    ↪ 'WeightedMonomialBasis | None' = None) -> 'CustomFunctionSpec'
```

Definition. Create a term sequence with `a[n+1]/a[n]=ratio(n)`.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · linear_recurrence_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.linear_recurrence_function`. Reflected implementation `komorebi_math.generating.functions.linear_recurrence_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', coefficients: 'tuple[int | Fraction, ...]', initial: 'tuple[int | Fraction, ...]', *, basis:
    ↪ 'WeightedMonomialBasis | None' = None) -> 'CustomFunctionSpec'
```

Definition. Create `a[n+d]=sum_j c_j a[n+j]`.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · multiplicative_series

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.multiplicative_series`. Reflected implementation `komorebi_math.generating.monoid.multiplicative_series`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-MONOID`.

Manifest signature (s).

```
(values: 'Iterable[int | Fraction]') -> 'FiniteMonoidSeries[int]'
```

Definition. Create coefficients indexed by positive integers, starting at one.

Contract (D, C, H, R, X). A finite monoid series stores a finite coefficient map, an index combination rule, an identity, and a name. Multiplication requires the same identity and combines only represented pairs, optionally filtered by an admissibility predicate. Additive series use nonnegative indices. Multiplicative series use positive integer indices. Dirichlet convolution validates a nonnegative count, and valuation packets require a prime of at least two.

Guarantees (E, P, B, K). Coefficient arithmetic is exact over `Fraction`. The class assumes that the index operation supplied by the caller is associative and does not prove that law. Dense finite multiplication is quadratic in the number of stored indices. Dirichlet convolution uses direct divisor enumeration for the requested prefix.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 24, and 25.

C.3A · ordinary_basis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.ordinary_basis`. Reflected implementation `komorebi_math.generating.basis.ordinary_basis`. The same runtime object is also exported as `komorebi_math.ordinary_basis`. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(*, name: 'str' = 'ordinary') -> 'WeightedMonomialBasis'
```

Definition. Return the ordinary generating-function basis `z^n`.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · partition_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.partition_numbers`. Reflected implementation `komorebi_math.generating.sequences.partition_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return partition numbers through Euler's pentagonal recurrence.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · pochhammer_basis

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.pochhammer_basis`. Reflected implementation `komorebi_math.generating.basis.pochhammer_basis`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (s).

```
(alpha: 'int | Fraction', *, name: 'str | None' = None) -> 'WeightedMonomialBasis'
```

Definition. Return `z^n/(alpha)_n` for a nonterminating rational path.

Contract (D, C, H, R, X). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (E, P, B, K). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · `prime_valuation_packets`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.prime_valuation_packets`. Reflected implementation `komorebi_math.generating.monoid.prime_valuation_packets`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-MONOID`.

Manifest signature (`s`).

```
(values: 'Iterable[int | Fraction]', prime: 'int') -> 'dict[int, tuple[tuple[int, Fraction], ...]]'
```

Definition. Group multiplicative coefficients by the exact prime-adic index valuation.

Contract (`D, C, H, R, X`). A finite monoid series stores a finite coefficient map, an index combination rule, an identity, and a name. Multiplication requires the same identity and combines only represented pairs, optionally filtered by an admissibility predicate. Additive series use nonnegative indices. Multiplicative series use positive integer indices. Dirichlet convolution validates a nonnegative count, and valuation packets require a prime of at least two.

Guarantees (`E, P, B, K`). Coefficient arithmetic is exact over `Fraction`. The class assumes that the index operation supplied by the caller is associative and does not prove that law. Dense finite multiplication is quadratic in the number of stored indices. Dirichlet convolution uses direct divisor enumeration for the requested prefix.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 24, and 25.

C.3A · `q_factorial_basis`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.q_factorial_basis`. Reflected implementation `komorebi_math.generating.basis.q_factorial_basis`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-BASIS`.

Manifest signature (`s`).

```
(q: 'int', *, name: 'str | None' = None) -> 'WeightedMonomialBasis'
```

Definition. Return the integer `q`-factorial basis.

Contract (`D, C, H, R, X`). A normalized monomial basis is defined by exact nonzero values `gamma_n` with `gamma_0=1`. Names must be nonempty. Indices and finite audit degrees must be nonnegative. Packet addresses must have a positive modulus and a valid residue. Declarative descriptors use a closed registry. Callback bases remain usable but are not portable unless replaced by a finite table descriptor.

Guarantees (`E, P, B, K`). Normalization, lowering weights, structure constants, packet transfer weights, and finite certificates use exact `Fraction` arithmetic. Finite audits establish only the requested degree range. Computing all structure constants through degree `d` requires a quadratic number of exact ratios, and numerator or denominator sizes can grow quickly.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_generating_domains.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 22, and 24.

C.3A · rational_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.rational_function`. Reflected implementation `komorebi_math.generating.functions.rational_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(name: 'str', numerator: 'tuple[int | Fraction, ...]', denominator: 'tuple[int | Fraction, ...]', *, basis:
   ↪  'WeightedMonomialBasis | None' = None) -> 'CustomFunctionSpec'
```

Definition. Create the coefficient sequence of one exact rational function.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · rational_gf_from_recurrence

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.rational_gf_from_recurrence`. Reflected implementation `komorebi_math.generating.closed_forms.rational_gf_from_recurrence`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-INFERENCE`.

Manifest signature (s).

```
(recurrence: 'LinearRecurrenceGuess', initial: 'Sequence[int | Fraction]') -> 'tuple[tuple[Fraction, ...],
   ↪  tuple[Fraction, ...]]'
```

Definition. Return numerator and denominator of the ordinary rational GF.

Contract (D, C, H, R, X). All guessers consume a finite exact prefix and search only within the declared order and degree bounds. A holdout separates fitted relations from later checks when enough data are available. Failure to find a candidate returns `None`. Guess records preserve the fit count, holdout count, and exact prefix status. Symbolic expression methods and characteristic forms require the optional SymPy backend.

Guarantees (E, P, B, K). Linear systems and residual checks use exact rational or integer arithmetic. A returned candidate is evidence for the supplied finite prefix, not a proof that the relation holds for every index. Search cost grows rapidly with the product of recurrence order, polynomial degree, and algebraic bidegree, so the explicit bounds are part of the contract.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · register_generating_codecs

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.register_generating_codecs`. Reflected implementation `komorebi_math.generating.portable.register_generating_codecs`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-PORTABLE`.

Manifest signature (s).

```
() -> 'None'
```

Definition. Register the trusted data-only generating-function codecs.

Contract (D, C, H, R, X). A frozen function requires nonempty names, a nonempty coefficient prefix, normalization of equal length beginning with one, no zero normalization values, and portable metadata. Reconstruction cannot exceed the captured degree. Freezing accepts only `CustomFunctionSpec`. Codec registration installs closed data only decoders and does not permit arbitrary Python object construction.

Guarantees (E, P, B, K). The frozen record preserves exact rational coefficients and basis normalization independently of the original callback. Roundtrip integrity is delegated to the project portable envelope and its digest checks. Serialization cost is linear in the captured prefix, subject to the global payload budget used by the persistence layer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 61, and 72.

C.3A · root_filter_value

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.root_filter_value`. Reflected implementation `komorebi_math.generating.sections.root_filter_value`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SECTION`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', modulus: 'int', residue: 'int', degree: 'int', z: 'complex') -> 'complex'
```

Definition. Evaluate the finite root filter of `E_gamma`.

Contract (D, C, H, R, X). The truncation degree must be nonnegative. A section requires a positive modulus and a residue in range. The signed option changes the lowering cycle convention but not the address rules. The audit compares one step, a full cycle, and a finite complex root filter at the supplied evaluation point.

Guarantees (E, P, B, K). Series coefficients and lowering operations are exact. The root filter is a finite floating point evaluation and is reported through a residual rather than exact equality. Construction is linear in the truncation degree, while an audit over all residue classes scales with both degree and modulus.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 25.

C.3A · series_to_fir_adapter

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.series_to_fir_adapter`. Reflected implementation `komorebi_math.generating.adapters.series_to_fir_adapter`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-ADAPTER`.

Manifest signature (s).

```
(series: 'FormalSeries', *, degree: 'int | None' = None, dtype: 'Any' = <class 'float'>) -> 'FIRSeriesAdapter'
```

Definition. Create an explicit formal-series to FIR adapter record.

Contract (D, C, H, R, X). FIR inputs must be a nonempty one dimensional finite real array. Conversion to `FormalSeries` rationalizes taps, optionally limiting denominators. Conversion from a series validates the requested degree and numeric dtype. An adapter requires one tap per stored ordinary coefficient. Frequency responses validate finite sampling parameters and certificates compare the declared coefficient to tap conversion.

Guarantees (E, P, B, K). The formal side is exact before conversion to NumPy. Tap arrays and frequency responses use floating point arithmetic, and their certificates are qualified by a stated tolerance. Conversion is linear in the number of taps. Frequency response evaluation delegates to the signal implementation and scales with the chosen point count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 31, and 66.

C.3A · series_to_fir_taps

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.series_to_fir_taps`. Reflected implementation `komorebi_math.generating.adapters.series_to_fir_taps`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-ADAPTER`.

Manifest signature (s).

```
(series: 'FormalSeries', *, degree: 'int | None' = None, dtype: 'Any' = <class 'float'>) -> 'np.ndarray'
```

Definition. Map ordinary coefficients to causal taps under `z -> z**(-1)`.

Contract (D, C, H, R, X). FIR inputs must be a nonempty one dimensional finite real array. Conversion to `FormalSeries` rationalizes taps, optionally limiting denominators. Conversion from a series validates the requested degree and numeric dtype. An adapter requires one tap per stored ordinary coefficient. Frequency responses validate finite sampling parameters and certificates compare the declared coefficient to tap conversion.

Guarantees (E, P, B, K). The formal side is exact before conversion to NumPy. Tap arrays and frequency responses use floating point arithmetic, and their certificates are qualified by a stated tolerance. Conversion is linear in the number of taps. Frequency response evaluation delegates to the signal implementation and scales with the chosen point count.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_block13.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21, 31, and 66.

C.3A · signed_euler_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.signed_euler_numbers`. Reflected implementation `komorebi_math.generating.sequences.signed_euler_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(count: 'int') -> 'tuple[int, ...]'
```

Definition. Return coefficients `E_n` of `sech(z)=sum E_n z^n/n!`.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused tests are `tests/test_generating_foundation.py` and `tests/test_arithmetic_euler.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · weighted_factorial_power_bell_function

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.weighted_factorial_power_bell_function`. Reflected implementation `komorebi_math.generating.functions.weighted_factorial_power_bell_function`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-FUNCTION`.

Manifest signature (s).

```
(power: 'int', weights: 'tuple[int | Fraction, ...] | Callable[[int], int | Fraction]', *, name: 'str | None' =
    ↪ None) -> 'CustomFunctionSpec'
```

Definition. Create a live custom block-weighted factorial-power Bell family.

Contract (D, C, H, R, X). A custom function has a nonempty name, an explicit normalized basis, a finite coefficient builder, a source kind, and portable metadata where required. Builders must return exactly `degree+1` coefficients. Recurrence seeds must match the recurrence order. Rational denominators need a nonzero constant. Algebraic branches require `P(0,y0)=0` and a nonzero partial derivative with respect to `y`. Registries reject duplicate names.

Guarantees (E, P, B, K). Each call constructs an exact finite `FormalSeries`. Rational, recurrence, hypergeometric, algebraic, Euler product, and Bell builders certify only the generated finite prefix. Runtime is polynomial in the requested degree for the implemented recurrences, but exact coefficient growth can dominate memory and arithmetic cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 21 through 24.

C.3A · weighted_generalized_bell_numbers

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.weighted_generalized_bell_numbers`. Reflected implementation `komorebi_math.generating.sequences.weighted_generalized_bell_numbers`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(power: 'int', count: 'int', weights: 'Iterable[int | Fraction] | Callable[[int], int | Fraction]') ->
   ↪ 'tuple[Fraction, ...]'
```

Definition. Evaluate the custom factorial-power Bell polynomials at `x=1`.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3A · weighted_generalized_bell_polynomials

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.weighted_generalized_bell_polynomials`. Reflected implementation `komorebi_math.generating.sequences.weighted_generalized_bell_polynomials`. In the reference manifest, this symbol is exported only from the generating namespace. The `komorebi_math.generating` route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-FOUND-SEQUENCE`.

Manifest signature (s).

```
(power: 'int', count: 'int', weights: 'Iterable[int | Fraction] | Callable[[int], int | Fraction]') ->
   ↪ 'tuple[tuple[Fraction, ...], ...]'
```

Definition. Return factorial-power Bell polynomials with custom block weights.

Contract (D, C, H, R, X). The requested count must be a nonnegative integer. Factorial power parameters must satisfy the positive order required by the family. Weighted Bell constructors accept either a finite weight source or a callback and require enough weights for the requested prefix. Returned tuples use the convention stated by each sequence, including `B_1=-1/2` and Fibonacci beginning at zero.

Guarantees (E, P, B, K). The functions return deterministic exact integer or rational prefixes. They establish the implemented recurrence or finite sum for those indices only. Most recurrences use quadratic work in the prefix length, while Apéry and weighted Bell sums can incur larger exact integer costs.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test is `tests/test_generating_foundation.py`. Together with the independent verifier for generating-function foundations, they exercise the applicable construction, exact identity, roundtrip, failure, optional backend, or resource boundary. The source validator for generating-function foundations checks the exact signature, implementation identity, facade routes, card counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B Arithmetic masks, automata, and prime-power compilers: 101 entries

This section closes the public `komorebi_math.generating` namespace. It records the arithmetic layer built above the normalized series contracts in C.3A. The layer combines local Mahler masks, finite carry plans, congruence audits, Cartier automata, Bell digit reductions, p-adic unit arithmetic, q-Kummer decompositions, normalized kernels, cyclotomic collapse, and digit-kernel convolution. Every contract remains finite and explicit about the range, modulus, truncation, state space, or resource budget that it certifies.

Contract family	Cards
Mahler masks and carry compilers	27
Finite congruence audits	16
Cartier automata and linear representations	14
Bell digit reductions	10
Prime-power unit arithmetic	8
q-Kummer decompositions	8
Normalized digit kernels	6
Cyclotomic collapse	6
Digit-kernel algebra	6
Total	**101**

The exact and finite boundary is central. Integer, rational, finite-field, and prime-power computations are exact in their declared domains. Analytic Mahler products attach a tail bound. Symbolic cyclotomic checks require the optional SymPy backend. Congruence audits, recurrence searches, and compiled finite-state certificates establish only the stored range unless a separate theorem extends the result.

C.3B · `AnalyticMaskApproximation`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.AnalyticMaskApproximation`. Reflected implementation `komorebi_math.generating.masks.AnalyticMaskApproximation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(radix: 'int', point: 'complex', terms: 'int', value: 'complex', relative_tail_bound: 'float',
   ↪ absolute_error_bound: 'float') -> None
```

Definition. Finite analytic Mahler product with a conservative tail bound.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `certificate`.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `AutomatonCertificate`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.AutomatonCertificate`. Reflected implementation `komorebi_math.generating.cartier.AutomatonCertificate`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(compared_terms: 'int', failures: 'tuple[tuple[int, int, int], ...]') -> None
```

Definition. Finite comparison between compiled and recurrence coefficients.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes. The principal public operations are `valid`, `require`.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `BellDigitReduction`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.BellDigitReduction`. Reflected implementation `komorebi_math.generating.bell.BellDigitReduction`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-BELL`.

Manifest signature (`s`).

```
(index: 'int', prime: 'int', factorial_power: 'int', digit_sum: 'int', high_polynomial: 'tuple[int, ...]',
    ↪ reduced_polynomial: 'tuple[int, ...]') -> None
```

Definition. One coefficientwise factorial-power Bell digit-sum reduction.

Contract (`D, C, H, R, X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction. The principal public operations are `valid`, `require`, `certificate`.

Guarantees (`E, P, B, K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · `BellParityAutomaton`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.BellParityAutomaton`. Reflected implementation `komorebi_math.generating.bell.BellParityAutomaton`. The same runtime object is also exported as `komorebi_math.BellParityAutomaton`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-BELL`.

Manifest signature (`s`).

```
(outputs: 'tuple[int, int, int]' = (1, 1, 0)) -> None
```

Definition. The three-state binary automaton for generalized Bell parity.

Contract (`D, C, H, R, X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction. The principal public operations are `transition`, `evaluate`.

Guarantees (`E, P, B, K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · `BellResidueAutomaton`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.BellResidueAutomaton`. Reflected implementation `komorebi_math.generating.bell.BellResidueAutomaton`. The same runtime object is also exported as `komorebi_math.BellResidueAutomaton`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-BELL`.

Manifest signature (`s`).

```
(prime: 'int', factorial_power: 'int', period_bound: 'int', outputs: 'tuple[int, ...]') -> None
```

Definition. A finite digit-sum automaton for factorial-power Bell residues.

Contract (`D, C, H, R, X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction. The principal public operations are `compile`, `transition`, `evaluate`, `certificate`.

Guarantees (`E, P, B, K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · `CarryLayerConvolution`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.CarryLayerConvolution`. Reflected implementation `komorebi_math.generating.masks.CarryLayerConvolution`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(index: 'int', prime: 'int', exponent: 'int', factorial_power: 'int', modulus: 'int', layer_sums: 'tuple[int,
   ↪  ...]') -> None
```

Definition. Prime-power convolution decomposed by exact borrow count.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `residue`.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `CarryLinearCertificate`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.CarryLinearCertificate`. Reflected implementation `komorebi_math.generating.normalization.CarryLinearCertificate`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-NORMALIZATION`.

Manifest signature (`s`).

```
(prime: 'int', linear_slope: 'int', carry_weight: 'int', checked_through: 'int', failures: 'tuple[tuple[int, int,
   ↪  int, int], ...]') -> None
```

Definition. Finite audit of the carry-linear valuation classification.

Contract (`D, C, H, R, X`). Digit-unit and normalized-kernel routines require a prime, nonnegative indices, and unit data compatible with the selected digit system. Carry-linear classification requires a callback with zero value at zero and a finite audit range large enough to recover the slope and carry weight. Invalid unit tables, primes, or audit ranges are rejected. The principal public operations are `valid`, `require`.

Guarantees (`E, P, B, K`). Local and digit-factorized normalized kernels are exact modulo the selected prime power. CarryLinearCertificate records the recovered profile and every finite mismatch. Passing the finite audit confirms the supplied range only. Kernel evaluation scales with the number of base-prime digits, while classification scales with the requested audit boundary.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 21, 24, and 26.

C.3B · `CarryLinearValuation`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.CarryLinearValuation`. Reflected implementation `komorebi_math.generating.normalization.CarryLinearValuation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-NORMALIZATION`.

Manifest signature (`s`).

```
(prime: 'int', linear_slope: 'int', carry_weight: 'int') -> None
```

Definition. Profile `nu(n)=a*n+s*v_p(n!)` with defect equal to weighted carries.

Contract (`D, C, H, R, X`). Digit-unit and normalized-kernel routines require a prime, nonnegative indices, and unit data compatible with the selected digit system. Carry-linear classification requires a callback with zero value at zero and a finite audit range large enough to recover the slope and carry weight. Invalid unit tables, primes, or audit ranges are rejected. The principal public operations are `value`, `defect`.

Guarantees (`E, P, B, K`). Local and digit-factorized normalized kernels are exact modulo the selected prime power. CarryLinearCertificate records the recovered profile and every finite mismatch. Passing the finite audit confirms the supplied range only. Kernel evaluation scales with the number of base-prime digits, while classification scales with the requested audit boundary.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 21, 24, and 26.

C.3B · `CartierAutomaton`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.CartierAutomaton`. Reflected implementation `komorebi_math.generating.cartier.CartierAutomaton`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(prime: 'int', numerator: 'tuple[int, ...]', denominator: 'tuple[int, ...]', degree_bound: 'int', transitions:
   ↪  'tuple[tuple[int, ...], ...]', outputs: 'tuple[int, ...]', state_numerators: 'tuple[tuple[int, ...], ...]',
   ↪  state_members: 'tuple[tuple[int, ...], ...]', start_state: 'int' = 0) -> None
```

Definition. Finite output automaton for a rational-mask Mahler series modulo a prime.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes. The principal public operations are `number_states`, `theoretical_state_bound`, `evaluate`, `sequence`, `certificate`.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · CartierCarryEquivalence

Identity (q, a, t, k). Public research manifest route komorebi_math.generating.CartierCarryEquivalence. Reflected implementation komorebi_math.generating.cartier.CartierCarryEquivalence. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by [RESEARCH] policy pre-beta-additive. Manifest kind class. Profile C3-ARITH-CARTIER.

Manifest signature (s).

```
(prime: 'int', dimension: 'int', failures: 'tuple[tuple[int, int, int, int, int], ...]') -> None
```

Definition. Finite certificate of Cartier/carry matrix equality.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes. The principal public operations are valid, require.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_generating_cartier_padic.py. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · CartierLinearRepresentation

Identity (q, a, t, k). Public research manifest route komorebi_math.generating.CartierLinearRepresentation. Reflected implementation komorebi_math.generating.cartier.CartierLinearRepresentation. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by [RESEARCH] policy pre-beta-additive. Manifest kind class. Profile C3-ARITH-CARTIER.

Manifest signature (s).

```
(prime: 'int', numerator: 'tuple[int, ...]', denominator: 'tuple[int, ...]', degree_bound: 'int',
    ↪ transition_matrices: 'tuple[tuple[tuple[int, ...], ...], ...]', start_vector: 'tuple[int, ...]',
    ↪ output_scale: 'int') -> None
```

Definition. Bounded-dimensional linear representation of a rational-mask series.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes. The principal public operations are dimension, transition, evaluate, sequence.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_generating_cartier_padic.py. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime owner-

ship. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `CyclotomicCollapse`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.CyclotomicCollapse`. Reflected implementation `komorebi_math.generating.cyclotomic.CyclotomicCollapse`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-CYCLOTOMIC`.

Manifest signature (`s`).

```
(prime: 'int', mask_exponents: 'tuple[tuple[int, int], ...]', closed_form_exponents: 'tuple[tuple[int, int],
   ↪  ...]', obstruction_orbits: 'tuple[int, ...]') -> None
```

Definition. Exact finite cyclotomic coboundary analysis.

Contract (`D, C, H, R, X`). Cyclotomic routines require a prime and positive cyclotomic indices. Exponent maps omit zero entries after normalization. Symbolic expression and verification functions require the optional SymPy backend. A collapse result retains every p-free obstruction orbit and raises when the caller demands a closed form that is not present. The principal public operations are `collapses`, `require`.

Guarantees (`E, P, B, K`). Orbit decomposition and exponent-lattice relations are exact. When no obstruction remains, the returned finite cyclotomic quotient is an exact formal collapse of the local Mahler product. Symbolic verification checks the declared relation rather than discovering a new one. Runtime is linear in the number of represented factors apart from optional symbolic simplification.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_cartier_padic.py` and `tests/test_generating_block13.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `DigitAlgebraAudit`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.DigitAlgebraAudit`. Reflected implementation `komorebi_math.generating.digit_algebra.DigitAlgebraAudit`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-DIGIT`.

Manifest signature (`s`).

```
(radix: 'int', modulus: 'int', power: 'int', tested_weights: 'int', weight_failures: 'int', tested_coefficients:
   ↪  'int', closure_failures: 'int', local_product: 'tuple[int, ...]') -> None
```

Definition. Finite evidence for digitwise factorization and convolution closure.

Contract (`D, C, H, R, X`). Digit kernels require a radix and modulus of at least two and one lower-triangular row for each digit. Global weights return zero when subtraction would borrow. Lifted sequences require one local value per digit. Factorial-power audits require a prime, positive power, and an explicit digit depth.

Guarantees (`E, P, B, K`). Local and global kernel weights, lifted sequences, and convolution audits are exact modulo the declared modulus. A finite DigitAlgebraAudit records the checked range and all failures. Digitwise evaluation is linear in the radix-digit width. Full closure audits scale with the size of the finite range and the number of tested subindices.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_foundation.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · DigitCauchyProductPlan

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.DigitCauchyProductPlan`. Reflected implementation `komorebi_math.generating.masks.DigitCauchyProductPlan`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(radix: 'int', digit_weights: 'tuple[tuple[Fraction, ...], ...]', matrices: 'tuple[Matrix, ...]') -> None
```

Definition. Finite carry representation of an ordinary product of digit-local series.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `factor_count`, `dimension`, `evaluate`, `sequence`.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · DigitKernel

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.DigitKernel`. Reflected implementation `komorebi_math.generating.digit_algebra.DigitKernel`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-DIGIT`.

Manifest signature (s).

```
(radix: 'int', modulus: 'int', table: 'tuple[tuple[int, ...], ...]', name: 'str' = 'digit kernel') -> None
```

Definition. A lower-triangular local convolution table modulo an integer. For digit `d` and subdigit `e`, `table[d][e]` is the local weight. The global no-borrow weight is the product of these local weights across radix digits. Entries above the diagonal are represented implicitly by zero.

Contract (D, C, H, R, X). Digit kernels require a radix and modulus of at least two and one lower-triangular row for each digit. Global weights return zero when subtraction would borrow. Lifted sequences require one local value per digit. Factorial-power audits require a prime, positive power, and an explicit digit depth. The principal public operations are `local_weight`, `global_weight`, `lift`, `local_multiply`, `global_multiply`.

Guarantees (E, P, B, K). Local and global kernel weights, lifted sequences, and convolution audits are exact modulo the declared modulus. A finite DigitAlgebraAudit records the checked range and all failures. Digitwise evaluation is linear in the radix-digit width. Full closure audits scale with the size of the finite range and the number of tested subindices.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_foundation.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `EulerProductCollapse`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.EulerProductCollapse`. Reflected implementation `komorebi_math.generating.masks.EulerProductCollapse`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(radix: 'int', mask_exponents: 'tuple[tuple[int, int], ...]', closed_form_exponents: 'tuple[tuple[int, int],
   ↪  ...]', obstruction_orbits: 'tuple[int, ...]') -> None
```

Definition. Orbitwise finite-collapse data for an Euler-product local mask.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `collapses`, `require`.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `FiniteMaskCarryPlan`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.FiniteMaskCarryPlan`. Reflected implementation `komorebi_math.generating.masks.FiniteMaskCarryPlan`. The same runtime object is also exported as `komorebi_math.FiniteMaskCarryPlan`. Within the generating namespace, `komorebi_math.generating.NormalizedMaskPlan` resolves to the same runtime object. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(radix: 'int', mask: 'tuple[Fraction, ...]', carry_bound: 'int', matrices: 'tuple[Matrix, ...]') -> None
```

Definition. Exact carry-matrix representation of a finite local mask.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `dimension`, `evaluate`, `sequence`, `certificate`.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite cer-

tificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · KummerLayerDistribution

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.KummerLayerDistribution`. Reflected implementation `komorebi_math.generating.masks.KummerLayerDistribution`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(index: 'int', prime: 'int', counts: 'tuple[int, ...]') -> None
```

Definition. Counts of subindices grouped by the number of base-prime borrows.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `total`, `count`, `support_count`, `certificate`.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · NormalizedKernelResidue

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.NormalizedKernelResidue`. Reflected implementation `komorebi_math.generating.padic_units.NormalizedKernelResidue`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', factorial_power: 'int', prime: 'int', exponent: 'int', valuation: 'int', unit:
   ↪  'int', residue: 'int') -> None
```

Definition. Prime-power residue of a carry-separable normalized-basis kernel.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required. The principal public operations are `survives`.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the

relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `NormalizedMaskPlan`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.NormalizedMaskPlan`. Reflected implementation `komorebi_math.generating.masks.FiniteMaskCarryPlan`. In the reference manifest, this symbol is exported only from the generating namespace. Within the generating namespace, `komorebi_math.generating.FiniteMaskCarryPlan` resolves to the same runtime object. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(radix: 'int', mask: 'tuple[Fraction, ...]', carry_bound: 'int', matrices: 'tuple[Matrix, ...]') -> None
```

Definition. Exact carry-matrix representation of a finite local mask.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `dimension`, `evaluate`, `sequence`, `certificate`.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `PointedSubindexCertificate`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.PointedSubindexCertificate`. Reflected implementation `komorebi_math.generating.bell.PointedSubindexCertificate`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-BELL`.

Manifest signature (`s`).

```
(index: 'int', prime: 'int', left: 'tuple[int, ...]', right: 'tuple[int, ...]') -> None
```

Definition. Exact finite certificate for the pointed digit identity.

Contract (`D, C, H, R, X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction. The principal public operations are `valid`, `require`, `certificate`.

Guarantees (`E, P, B, K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The in-

dependent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · PolynomialCoboundaryResult

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PolynomialCoboundaryResult`. Reflected implementation `komorebi_math.generating.masks.PolynomialCoboundaryResult`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(radix: 'int', degree_bound: 'int', coefficients: 'tuple[Fraction, ...] | None', residual: 'tuple[Fraction, ...]')
   ↪ -> None
```

Definition. Bounded exact solution of `B Q=A Q(z^radix)` with `Q(0)=1`.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `found`, `valid`, `require`, `certificate`.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · PrimePowerBinomial

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PrimePowerBinomial`. Reflected implementation `komorebi_math.generating.padic_units.PrimePowerBinomial`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', prime: 'int', exponent: 'int', modulus: 'int', valuation: 'int', unit: 'int',
   ↪ residue: 'int') -> None
```

Definition. Valuation, unit part, and residue of a binomial coefficient.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required. The principal public operations are `survives`.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · PrimePowerKernelCompiler

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PrimePowerKernelCompiler`. Reflected implementation `komorebi_math.generating.padic_units.PrimePowerKernelCompiler`. The same runtime object is also exported as `komorebi_math.PrimePowerKernelCompiler`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(prime: 'int', exponent: 'int', factorial_power: 'int', unit_sequence: 'Callable[[int], int] | None' = None,
    ↪ max_modulus: 'int' = 2000000) -> None
```

Definition. Compile kernels for `gamma_n=c**n (n!)**s u_n` modulo `p**r`. The geometric factor cancels from every structure constant. The supplied `unit_sequence` must take values coprime to `p`.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required. The principal public operations are `modulus`, `kernel`.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · PrimePowerUnitCompiler

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.PrimePowerUnitCompiler`. Reflected implementation `komorebi_math.generating.padic_units.PrimePowerUnitCompiler`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(prime: 'int', exponent: 'int', max_modulus: 'int' = 2000000) -> None
```

Definition. Compile p-free factorials and binomial residues modulo `p**r`. The prefix table costs `O(p**r)` memory. Each query then uses `O(log_p(n))` iterations, with memoization of completed unit factorials.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required. The principal public operations are `unit_factorial`, `binomial_data`, `binomial`.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is rep-

resented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `QKummerDecomposition`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.QKummerDecomposition`. Reflected implementation `komorebi_math.generating.q_kummer.QKummerDecomposition`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-QKUMMER`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', base: 'int', prime: 'int', order: 'int', lift_constant: 'int', quotient_index:
   ↪ 'int', quotient_subindex: 'int', residue_carry: 'int', quotient_carries: 'int', endpoint_valuation: 'int',
   ↪ valuation: 'int') -> None
```

Definition. Exact mixed-radix valuation decomposition for a Gaussian binomial.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract. The principal public operations are `survives`.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `RationalMaskAlgebraicCertificate`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.RationalMaskAlgebraicCertificate`. Reflected implementation `komorebi_math.generating.masks.RationalMaskAlgebraicCertificate`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `class`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(prime: 'int', degree: 'int', failures: 'tuple[tuple[int, int], ...]') -> None
```

Definition. Finite exact certificate for `A F^(p-1)=B` modulo a prime.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution. The principal public operations are `valid`, `require`, `certificate`.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products

are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `analytic_mahler_product`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.analytic_mahler_product`. Reflected implementation `komorebi_math.generating.masks.analytic_mahler_product`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(mask: 'Sequence[int | float | complex | Fraction]', point: 'complex', radix: 'int', terms: 'int') ->
    ↪ 'AnalyticMaskApproximation'
```

Definition. Evaluate a finite analytic scale product with an explicit tail bound. For `R(z)=1+sum_(k>=1) r_k z^k` and `|z|<1`, the implementation uses `|R(w)-1| <= C|w|` with `C=sum_(k>=1)|r_k|`. The resulting bound is conservative. It is numerical rather than interval-rigorous because the product itself is evaluated with ordinary complex floating arithmetic.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `audit_apery_supercongruence`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_apery_supercongruence`. Reflected implementation `komorebi_math.generating.congruences.audit_apery_supercongruence`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(values: 'Sequence[int]', prime: 'int', exponent: 'int' = 3) -> 'RelationAudit'
```

Definition. Verify `A_(p*n)=A_n (mod p^exponent)` on the available prefix.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_factorial_power_digit_algebra

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_factorial_power_digit_algebra`. Reflected implementation `komorebi_math.generating.digit_algebra.audit_factorial_power_digit_algebra`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-DIGIT`.

Manifest signature (s).

```
(*, prime: 'int', power: 'int', left_digits: 'Iterable[int]', right_digits: 'Iterable[int]', max_digits: 'int' =
   ↪ 3) -> 'DigitAlgebraAudit'
```

Definition. Audit Lucas-compatible closure below `prime^max_digits`. The theorem being tested is `(a star_s b)_n = prod_i (a star_s b)_(n_i) (mod p)` whenever `a_n` and `b_n` are lifted products of their base-`p` digit values and `star_s` uses `binom(n,k)^s`.

Contract (D, C, H, R, X). Digit kernels require a radix and modulus of at least two and one lower-triangular row for each digit. Global weights return zero when subtraction would borrow. Lifted sequences require one local value per digit. Factorial-power audits require a prime, positive power, and an explicit digit depth.

Guarantees (E, P, B, K). Local and global kernel weights, lifted sequences, and convolution audits are exact modulo the declared modulus. A finite DigitAlgebraAudit records the checked range and all failures. Digitwise evaluation is linear in the radix-digit width. Full closure audits scale with the size of the finite range and the number of tested subindices.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_foundation.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · audit_factorial_power_packet_convolution

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_factorial_power_packet_convolution`. Reflected implementation `komorebi_math.generating.congruences.audit_factorial_power_packet_convolution`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(left: 'Sequence[int]', right: 'Sequence[int]', *, power: 'int', prime: 'int') -> 'ConvolutionPacketAudit'
```

Definition. Verify the Lucas/polyphase convolution identity modulo a prime.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself.

Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_generalized_bell_digit_sum

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_generalized_bell_digit_sum`. Reflected implementation `komorebi_math.generating.congruences.audit_generalized_bell_digit_sum`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(*, prime: 'int', power: 'int', count: 'int' = 300) -> 'DigitSumCongruenceAudit'
```

Definition. Verify `B_n^(s)(x)=B_(s_p(n))(x) (mod p)` on a finite range.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_generalized_lucas

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_generalized_lucas`. Reflected implementation `komorebi_math.generating.congruences.audit_generalized_lucas`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(basis: 'WeightedMonomialBasis', *, prime: 'int', high_limit: 'int' = 12) -> 'LucasBasisAudit'
```

Definition. Test `C(pn+r,pk+i)=C(n,k)C(r,i) (mod p)` when integral.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_partition_lane

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_partition_lane`. Reflected implementation `komorebi_math.generating.congruences.audit_partition_lane`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(values: 'Sequence[int]', prime: 'int', residue: 'int') -> 'RelationAudit'
```

Definition. Audit divisibility by `prime` on indices `prime*n + residue`.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_q_lucas

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_q_lucas`. Reflected implementation `komorebi_math.generating.congruences.audit_q_lucas`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(*, q: 'int', prime: 'int', high_limit: 'int' = 10) -> 'QLucasAudit'
```

Definition. Audit the order-radix Gaussian-binomial Lucas law. If `d` is the multiplicative order of `q` modulo `p`, the tested identity is `[ad+b choose rd+s]_q = C(a,r) [b choose s]_q (mod p)`.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite

certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_touchard

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_touchard`. Reflected implementation `komorebi_math.generating.congruences.audit_touchard`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(values: 'Sequence[int]', prime: 'int') -> 'RelationAudit'
```

Definition. Verify `B_(n+p)=B_(n+1)+B_n (mod p)` on a prefix.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · audit_weighted_generalized_bell_digit_sum

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.audit_weighted_generalized_bell_digit_sum`. Reflected implementation `komorebi_math.generating.congruences.audit_weighted_generalized_bell_digit_sum`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(*, prime: 'int', power: 'int', digit_weights: 'Sequence[int]', count: 'int' = 300) ->
    ↪ 'WeightedDigitSumCongruenceAudit'
```

Definition. Audit a custom weighted factorial-power Bell congruence. Let `c_m = d_(s_p(m))` and define `F(z,x)=exp( x*sum_(m>=1) c_m z^m/(m!)^power)`. When `power >= 2` and `power-1` is divisible by `prime-1`, the normalized coefficient polynomial at index `n` is predicted to equal, modulo `prime`, the ordinary weighted Bell polynomial at `s_p(n)` with block weights `d_t`.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite

certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · base_digit_sum

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.base_digit_sum`. Reflected implementation `komorebi_math.generating.congruences.base_digit_sum`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(index: 'int', base: 'int') -> 'int'
```

Definition. Return the sum of the nonnegative integer index digits in the declared base.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · base_digits

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.base_digits`. Reflected implementation `komorebi_math.generating.digit_algebra.base_digits`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-DIGIT`.

Manifest signature (s).

```
(index: 'int', radix: 'int') -> 'tuple[int, ...]'
```

Definition. Return least-significant-first digits, with zero represented by `(0,)`.

Contract (D, C, H, R, X). Digit kernels require a radix and modulus of at least two and one lower-triangular row for each digit. Global weights return zero when subtraction would borrow. Lifted sequences require one local value per digit. Factorial-power audits require a prime, positive power, and an explicit digit depth.

Guarantees (E, P, B, K). Local and global kernel weights, lifted sequences, and convolution audits are exact modulo the declared modulus. A finite DigitAlgebraAudit records the checked range and all failures. Digitwise evaluation is linear in the radix-digit width. Full closure audits scale with the size of the finite range and the number of tested subindices.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_foundation.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `bell_period_bound`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.bell_period_bound`. Reflected implementation `komorebi_math.generating.bell.bell_period_bound`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-BELL`.

Manifest signature (`s`).

```
(prime: 'int') -> 'int'
```

Definition. Return `(p**p-1)/(p-1)`, a period bound modulo `p`.

Contract (`D, C, H, R, X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (`E, P, B, K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · `berlekamp_massey`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.berlekamp_massey`. Reflected implementation `komorebi_math.generating.congruences.berlekamp_massey`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (`s`).

```
(values: 'Sequence[int]', prime: 'int') -> 'tuple[int, tuple[int, ...]]'
```

Definition. Return the minimal recurrence over a prime field for the supplied prefix.

Contract (`D, C, H, R, X`). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (`E, P, B, K`). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · binomial_valuation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.binomial_valuation`. Reflected implementation `komorebi_math.generating.padic_units.binomial_valuation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', prime: 'int') -> 'int'
```

Definition. Return `v_prime(binomial(index,subindex))`.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · borrow_count

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.borrow_count`. Reflected implementation `komorebi_math.generating.padic_units.borrow_count`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', prime: 'int') -> 'int'
```

Definition. Count base-p borrows in subtracting `subindex` from `index`.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `cartier_degree_bound`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.cartier_degree_bound`. Reflected implementation `komorebi_math.generating.cartier.cartier_degree_bound`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(numerator: 'Sequence[int]', denominator: 'Sequence[int]', prime: 'int') -> 'int'
```

Definition. Return a degree bound invariant under every rational-mask transition.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `certify_cartier_carry_equivalence`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.certify_cartier_carry_equivalence`. Reflected implementation `komorebi_math.generating.cartier.certify_cartier_carry_equivalence`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(mask: 'Sequence[int]', prime: 'int', *, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'CartierCarryEquivalence'
```

Definition. Certify that finite-mask carry matrices are Cartier multiplication matrices.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · certify_mahler_functional_equation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.certify_mahler_functional_equation`. Reflected implementation `komorebi_math.generating.masks.certify_mahler_functional_equation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(series: 'Iterable[Scalar]', mask: 'Iterable[Scalar]', radix: 'int', degree: 'int | None' = None, *, budget:
    ↪ 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000,
    ↪ maximum_matrix_dimension=4096, maximum_reachable_states=100000, maximum_local_combinations=1000000,
    ↪ maximum_modulus=2000000, maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'Certificate'
```

Definition. Certify `F(z)=R(z)F(z**radix)` on a declared finite truncation.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · certify_pointed_subindex_identity

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.certify_pointed_subindex_identity`. Reflected implementation `komorebi_math.generating.bell.certify_pointed_subindex_identity`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-BELL`.

Manifest signature (s).

```
(index: 'int', prime: 'int') -> 'PointedSubindexCertificate'
```

Definition. Certify the pointed subindex polynomial against `(1+u)^(s_p(n)-1)`.

Contract (D, C, H, R, X). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (E, P, B, K). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · certify_rational_mask_algebraic_relation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.certify_rational_mask_algebraic_relation`. Reflected implementation `komorebi_math.generating.masks.certify_rational_mask_algebraic_relation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(numerator: 'Sequence[int]', denominator: 'Sequence[int]', prime: 'int', degree: 'int', *, budget:
    ↪ 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000,
    ↪ maximum_matrix_dimension=4096, maximum_reachable_states=100000, maximum_local_combinations=1000000,
    ↪ maximum_modulus=2000000, maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) ->
    ↪ 'RationalMaskAlgebraicCertificate'
```

Definition. Certify `A(z)F(z)^(p-1)=B(z)` modulo `p` through `degree`.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · classify_carry_linear_valuation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.classify_carry_linear_valuation`. Reflected implementation `komorebi_math.generating.normalization.classify_carry_linear_valuation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-NORMALIZATION`.

Manifest signature (s).

```
(valuation: 'Callable[[int], int]', prime: 'int', checked_through: 'int') -> 'CarryLinearCertificate'
```

Definition. Recover the profile parameters and audit a finite range. The mathematical classification is unbounded. This routine is explicitly a finite certificate for a supplied callback.

Contract (D, C, H, R, X). Digit-unit and normalized-kernel routines require a prime, nonnegative indices, and unit data compatible with the selected digit system. Carry-linear classification requires a callback with zero value at zero and a finite audit range large enough to recover the slope and carry weight. Invalid unit tables, primes, or audit ranges are rejected.

Guarantees (E, P, B, K). Local and digit-factorized normalized kernels are exact modulo the selected prime power. CarryLinearCertificate records the recovered profile and every finite mismatch. Passing the finite audit confirms the supplied range only. Kernel evaluation scales with the number of base-prime digits, while classification scales with the requested audit boundary.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime owner-

ship. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 21, 24, and 26.

C.3B · `compile_cartier_linear_representation`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.compile_cartier_linear_representation`. Reflected implementation `komorebi_math.generating.cartier.compile_cartier_linear_representation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(numerator: 'Sequence[int]', denominator: 'Sequence[int]', prime: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'CartierLinearRepresentation'
```

Definition. Compile the denominator-stabilized Cartier transition matrices.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `compile_digit_cauchy_product`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.compile_digit_cauchy_product`. Reflected implementation `komorebi_math.generating.masks.compile_digit_cauchy_product`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(digit_weights: 'Sequence[Sequence[Scalar]]', radix: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'DigitCauchyProductPlan'
```

Definition. Compile finite carries for a Cauchy product of digit-local sequences.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products

are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `compile_finite_mask_carry_plan`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.compile_finite_mask_carry_plan`. Reflected implementation `komorebi_math.generating.masks.compile_finite_mask_carry_plan`. The same runtime object is also exported as `komorebi_math.compile_finite_mask_carry_plan`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(mask: 'Iterable[Scalar]', radix: 'int', *, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'FiniteMaskCarryPlan'
```

Definition. Compile `T_d(q,q')=r_(d+radix*q'-q)` for a finite mask.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `compile_rational_mask_automaton`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.compile_rational_mask_automaton`. Reflected implementation `komorebi_math.generating.cartier.compile_rational_mask_automaton`. The same runtime object is also exported as `komorebi_math.compile_rational_mask_automaton`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (s).

```
(numerator: 'Sequence[int]', denominator: 'Sequence[int]', prime: 'int', *, minimize: 'bool' = True, max_states:
    ↪ 'int' = 100000, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'CartierAutomaton'
```

Definition. Compile a rational Mahler mask into a coefficient automaton modulo `prime`. The degree-derived linear dimension and the reachable-state guard are checked before state exploration begins.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `cyclotomic_coboundary`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.cyclotomic_coboundary`. Reflected implementation `komorebi_math.generating.cyclotomic.cyclotomic_coboundary`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CYCLOTOMIC`.

Manifest signature (s).

```
(prime: 'int', exponents: 'Mapping[int, int]') -> 'CyclotomicCollapse'
```

Definition. Solve `R(z)=Q(z)/Q(z**p)` for a finite cyclotomic mask. Factors are normalized to constant coefficient one. The exact obstruction is a nonzero exponent at level zero of a p-power orbit.

Contract (D, C, H, R, X). Cyclotomic routines require a prime and positive cyclotomic indices. Exponent maps omit zero entries after normalization. Symbolic expression and verification functions require the optional SymPy backend. A collapse result retains every p-free obstruction orbit and raises when the caller demands a closed form that is not present.

Guarantees (E, P, B, K). Orbit decomposition and exponent-lattice relations are exact. When no obstruction remains, the returned finite cyclotomic quotient is an exact formal collapse of the local Mahler product. Symbolic verification checks the declared relation rather than discovering a new one. Runtime is linear in the number of represented factors apart from optional symbolic simplification.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_cartier_padic.py` and `tests/test_generating_block13.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `difference_valuation_profile`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.difference_valuation_profile`. Reflected implementation `komorebi_math.generating.congruences.difference_valuation_profile`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (`s`).

```
(values: 'Sequence[int | Fraction]', *, prime: 'int', step: 'int', max_order: 'int') ->
    ↪ 'DifferenceValuationProfile'
```

Definition. Measure minimum `p`-adic valuations of successive stepped differences.

Contract (`D, C, H, R, X`). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (`E, P, B, K`). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `digit_factorized_normalized_kernel`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.digit_factorized_normalized_kernel`. Reflected implementation `komorebi_math.generating.normalization.digit_factorized_normalized_kernel`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-NORMALIZATION`.

Manifest signature (`s`).

```
(index: 'int', subindex: 'int', prime: 'int', factorial_power: 'int', unit_weights: 'Sequence[int]') -> 'int'
```

Definition. Multiply the local normalized kernels over all base-p digits.

Contract (`D, C, H, R, X`). Digit-unit and normalized-kernel routines require a prime, nonnegative indices, and unit data compatible with the selected digit system. Carry-linear classification requires a callback with zero value at zero and a finite audit range large enough to recover the slope and carry weight. Invalid unit tables, primes, or audit ranges are rejected.

Guarantees (`E, P, B, K`). Local and digit-factorized normalized kernels are exact modulo the selected prime power. CarryLinearCertificate records the recovered profile and every finite mismatch. Passing the finite audit confirms the supplied range only. Kernel evaluation scales with the number of base-prime digits, while classification scales with the requested audit boundary.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 21, 24, and 26.

C.3B · `digit_unit`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.digit_unit`. Reflected implementation `komorebi_math.generating.normalization.digit_unit`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-NORMALIZATION`.

Manifest signature (`s`).

```
(index: 'int', prime: 'int', weights: 'Sequence[int]') -> 'int'
```

Definition. Evaluate a digit-multiplicative p-adic unit profile modulo `prime`.

Contract (`D, C, H, R, X`). Digit-unit and normalized-kernel routines require a prime, nonnegative indices, and unit data compatible with the selected digit system. Carry-linear classification requires a callback with zero value at zero and a finite audit range large enough to recover the slope and carry weight. Invalid unit tables, primes, or audit ranges are rejected.

Guarantees (`E, P, B, K`). Local and digit-factorized normalized kernels are exact modulo the selected prime power. CarryLinearCertificate records the recovered profile and every finite mismatch. Passing the finite audit confirms the supplied range only. Kernel evaluation scales with the number of base-prime digits, while classification scales with the requested audit boundary.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 21, 24, and 26.

C.3B · `euler_product_collapse`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.euler_product_collapse`. Reflected implementation `komorebi_math.generating.masks.euler_product_collapse`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(radix: 'int', exponents: 'Mapping[int, int]') -> 'EulerProductCollapse'
```

Definition. Compute the finite Euler product represented by a local Euler mask.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `factorial_power_convolution_layers`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.factorial_power_convolution_layers`. Reflected implementation `komorebi_math.generating.masks.factorial_power_convolution_layers`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(left: 'Sequence[int]', right: 'Sequence[int]', index: 'int', prime: 'int', factorial_power: 'int',
    ↪ modulus_exponent: 'int', *, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'CarryLayerConvolution'
```

Definition. Evaluate a factorial-power convolution and retain each carry layer.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `factorial_power_digit_kernel`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.factorial_power_digit_kernel`. Reflected implementation `komorebi_math.generating.digit_algebra.factorial_power_digit_kernel`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-DIGIT`.

Manifest signature (`s`).

```
(power: 'int', prime: 'int') -> 'DigitKernel'
```

Definition. Return the Lucas table for `binom(n,k)^power` modulo `prime`.

Contract (`D, C, H, R, X`). Digit kernels require a radix and modulus of at least two and one lower-triangular row for each digit. Global weights return zero when subtraction would borrow. Lifted sequences require one local value per digit. Factorial-power audits require a prime, positive power, and an explicit digit depth.

Guarantees (`E, P, B, K`). Local and global kernel weights, lifted sequences, and convolution audits are exact modulo the declared modulus. A finite DigitAlgebraAudit records the checked range and all failures. Digitwise evaluation is linear in the radix-digit width. Full closure audits scale with the size of the finite range and the number of tested subindices.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_foundation.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · factorial_power_support_count

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.factorial_power_support_count`. Reflected implementation `komorebi_math.generating.masks.factorial_power_support_count`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(index: 'int', prime: 'int', factorial_power: 'int', modulus_exponent: 'int') -> 'int'
```

Definition. Count `k` for which `binomial(index,k)**power` survives modulo `p**r`.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · factorial_power_support_indices

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.factorial_power_support_indices`. Reflected implementation `komorebi_math.generating.masks.factorial_power_support_indices`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(index: 'int', prime: 'int', factorial_power: 'int', modulus_exponent: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'tuple[int, ...]'
```

Definition. Enumerate the surviving subindices under an explicit finite budget.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite cer-

tificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · factorial_valuation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.factorial_valuation`. Reflected implementation `komorebi_math.generating.padic_units.factorial_valuation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(index: 'int', prime: 'int') -> 'int'
```

Definition. Return `v_prime(index!)` by Legendre's formula.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · finite_mask_carry_matrices

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.finite_mask_carry_matrices`. Reflected implementation `komorebi_math.generating.cartier.finite_mask_carry_matrices`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (s).

```
(mask: 'Sequence[int]', prime: 'int', *, budget: 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000,
    ↪ maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096, maximum_reachable_states=100000,
    ↪ maximum_local_combinations=1000000, maximum_modulus=2000000, maximum_serialized_bytes=67108864,
    ↪ maximum_recursion_depth=1000)) -> 'tuple[tuple[tuple[int, ...], ...], ...]'
```

Definition. Return finite-mask carry matrices `T_d(q,q')=r[d+p*q'-q]`.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime owner-

ship. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `first_frobenius_lift`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.first_frobenius_lift`. Reflected implementation `komorebi_math.generating.masks.first_frobenius_lift`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(mask: 'Sequence[int]', prime: 'int', degree: 'int') -> 'tuple[int, ...]'
```

Definition. Return `(R(z**p)/R(z)**p-1)/p` modulo `p` when integral.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `frobenius_defect_mask`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.frobenius_defect_mask`. Reflected implementation `komorebi_math.generating.masks.frobenius_defect_mask`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(mask: 'Iterable[Scalar]', prime: 'int', degree: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'tuple[Fraction, ...]'
```

Definition. Return `R(z**p)/R(z)**p` through a finite degree.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `gaussian_binomial`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.gaussian_binomial`. Reflected implementation `komorebi_math.generating.q_kummer.gaussian_binomial`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-QKUMMER`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', base: 'int') -> 'int'
```

Definition. Return the integer Gaussian binomial evaluated at `base`.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `generalized_bell_digit_reduction`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.generalized_bell_digit_reduction`. Reflected implementation `komorebi_math.generating.bell.generalized_bell_digit_reduction`. The same runtime object is also exported as `komorebi_math.generalized_bell_digit_reduction`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-BELL`.

Manifest signature (s).

```
(index: 'int', prime: 'int', factorial_power: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'BellDigitReduction'
```

Definition. Compute and certify the unweighted Bell digit theorem at one index.

Contract (D, C, H, R, X). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (E, P, B, K). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · generalized_bell_parity

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.generalized_bell_parity`. Reflected implementation `komorebi_math.generating.bell.generalized_bell_parity`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-BELL`.

Manifest signature (s).

```
(index: 'int', factorial_power: 'int') -> 'int'
```

Definition. Return the exact parity predicted by the population-count automaton.

Contract (D, C, H, R, X). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (E, P, B, K). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · integer_valuation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.integer_valuation`. Reflected implementation `komorebi_math.generating.padic_units.integer_valuation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-PADIC`.

Manifest signature (s).

```
(value: 'int', prime: 'int') -> 'int'
```

Definition. Return the finite p-adic valuation of a nonzero integer.

Contract (D, C, H, R, X). Valuation functions require a prime and valid integer or binomial indices. Prime-power compilers require positive precision and a modulus within the supplied budget. Unit-factorial and binomial methods distinguish valuation from the invertible unit part. Kernel compilers require compatible digit-unit tables and factorial exponents. Borrow counts use nonnegative indices with the subindex not exceeding the index where required.

Guarantees (E, P, B, K). Valuations, unit parts, residues, and survival decisions are exact for the declared prime power. PrimePowerBinomial separates the p-adic valuation from the unit residue, so zero modulo the prime power is represented without discarding valuation information. Precomputation cost depends on the prime-power modulus. Subsequent digit recursions scale with the number of base-prime digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime owner-

ship. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · kummer_layer_distribution

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.kummer_layer_distribution`. Reflected implementation `komorebi_math.generating.masks.kummer_layer_distribution`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(index: 'int', prime: 'int') -> 'KummerLayerDistribution'
```

Definition. Return the coefficient polynomial counting `v_p(binomial(index,k))`.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · lift_digit_sequence

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.lift_digit_sequence`. Reflected implementation `komorebi_math.generating.digit_algebra.lift_digit_sequence`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-DIGIT`.

Manifest signature (s).

```
(digit_values: 'Sequence[int]', *, radix: 'int', modulus: 'int', count: 'int') -> 'tuple[int, ...]'
```

Definition. Lift a local table without coupling it to a particular kernel.

Contract (D, C, H, R, X). Digit kernels require a radix and modulus of at least two and one lower-triangular row for each digit. Global weights return zero when subtraction would borrow. Lifted sequences require one local value per digit. Factorial-power audits require a prime, positive power, and an explicit digit depth.

Guarantees (E, P, B, K). Local and global kernel weights, lifted sequences, and convolution audits are exact modulo the declared modulus. A finite DigitAlgebraAudit records the checked range and all failures. Digitwise evaluation is linear in the radix-digit width. Full closure audits scale with the size of the finite range and the number of tested subindices.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_foundation.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `local_normalized_kernel`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.local_normalized_kernel`. Reflected implementation `komorebi_math.generating.normalization.local_normalized_kernel`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-NORMALIZATION`.

Manifest signature (`s`).

```
(total_digit: 'int', selected_digit: 'int', prime: 'int', factorial_power: 'int', unit_weights: 'Sequence[int]')
   ↪  -> 'int'
```

Definition. Return the no-carry local kernel for a digit-twisted factorial basis.

Contract (`D, C, H, R, X`). Digit-unit and normalized-kernel routines require a prime, nonnegative indices, and unit data compatible with the selected digit system. Carry-linear classification requires a callback with zero value at zero and a finite audit range large enough to recover the slope and carry weight. Invalid unit tables, primes, or audit ranges are rejected.

Guarantees (`E, P, B, K`). Local and digit-factorized normalized kernels are exact modulo the selected prime power. CarryLinearCertificate records the recovered profile and every finite mismatch. Passing the finite audit confirms the supplied range only. Kernel evaluation scales with the number of base-prime digits, while classification scales with the requested audit boundary.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 21, 24, and 26.

C.3B · `mahler_coefficients`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.mahler_coefficients`. Reflected implementation `komorebi_math.generating.congruences.mahler_coefficients`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (`s`).

```
(values: 'Iterable[int | Fraction]') -> 'tuple[Fraction, ...]'
```

Definition. Return finite Newton/Mahler coefficients `Delta^r f(0)`.

Contract (`D, C, H, R, X`). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (`E, P, B, K`). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · mahler_mask_inverse

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.mahler_mask_inverse`. Reflected implementation `komorebi_math.generating.masks.mahler_mask_inverse`. The same runtime object is also exported as `komorebi_math.mahler_mask_inverse`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(series: 'Iterable[Scalar]', radix: 'int', degree: 'int | None' = None, *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'tuple[Fraction, ...]'
```

Definition. Recover the unique local mask `R(z)=F(z)/F(z**radix)`.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · mahler_mask_product

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.mahler_mask_product`. Reflected implementation `komorebi_math.generating.masks.mahler_mask_product`. The same runtime object is also exported as `komorebi_math.mahler_mask_product`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(mask: 'Iterable[Scalar]', radix: 'int', degree: 'int', *, budget: 'GeneratingBudget' =
    ↪ GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'tuple[Fraction, ...]'
```

Definition. Return `prod_(j>=0) R(z**radix**j)` through `z**degree`. Only finitely many mask levels affect a finite truncation. Arithmetic uses exact `fractions.Fraction` values.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `minimal_prefix_period`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.minimal_prefix_period`. Reflected implementation `komorebi_math.generating.congruences.minimal_prefix_period`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(values: 'Sequence[int]', modulus: 'int', *, preperiod_limit: 'int' = 0) -> 'tuple[int, int] | None'
```

Definition. Return a finite-prefix preperiod/period certificate when visible.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `minimize_cartier_automaton`

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.minimize_cartier_automaton`. Reflected implementation `komorebi_math.generating.cartier.minimize_cartier_automaton`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (s).

```
(automaton: 'CartierAutomaton') -> 'CartierAutomaton'
```

Definition. Minimize an output automaton by exact partition refinement.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the

relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `multiplicative_order_mod_prime`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.multiplicative_order_mod_prime`. Reflected implementation `komorebi_math.generating.q_kummer.multiplicative_order_mod_prime`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-QKUMMER`.

Manifest signature (`s`).

```
(value: 'int', prime: 'int') -> 'int'
```

Definition. Return the multiplicative order of `value` modulo `prime`.

Contract (`D, C, H, R, X`). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (`E, P, B, K`). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `normalized_cyclotomic_expression`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.normalized_cyclotomic_expression`. Reflected implementation `komorebi_math.generating.cyclotomic.normalized_cyclotomic_expression`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CYCLOTOMIC`.

Manifest signature (`s`).

```
(exponents: 'Mapping[int, int]') -> 'Any'
```

Definition. Return a SymPy expression for normalized cyclotomic factors.

Contract (`D, C, H, R, X`). Cyclotomic routines require a prime and positive cyclotomic indices. Exponent maps omit zero entries after normalization. Symbolic expression and verification functions require the optional SymPy backend. A collapse result retains every p-free obstruction orbit and raises when the caller demands a closed form that is not present.

Guarantees (`E, P, B, K`). Orbit decomposition and exponent-lattice relations are exact. When no obstruction remains, the returned finite cyclotomic quotient is an exact formal collapse of the local Mahler product. Symbolic verification checks the declared relation rather than discovering a new one. Runtime is linear in the number of represented factors apart from optional symbolic simplification.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_cartier_padic.py` and `tests/test_generating_block13.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · one_borrow_count

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.one_borrow_count`. Reflected implementation `komorebi_math.generating.masks.one_borrow_count`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(index: 'int', prime: 'int') -> 'int'
```

Definition. Return the exact number of subindices producing exactly one borrow.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · p_adic_valuation_fraction

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.p_adic_valuation_fraction`. Reflected implementation `komorebi_math.generating.congruences.p_adic_valuation_fraction`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(value: 'int | Fraction', prime: 'int') -> 'int | float'
```

Definition. Return the exact p-adic valuation of a rational, with infinity at zero.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · p_free_orbit

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.p_free_orbit`. Reflected implementation `komorebi_math.generating.cyclotomic.p_free_orbit`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CYCLOTOMIC`.

Manifest signature (s).

```
(index: 'int', prime: 'int') -> 'tuple[int, int]'
```

Definition. Return `(u,k)` with `index=u*prime**k` and `p` not dividing `u`.

Contract (D, C, H, R, X). Cyclotomic routines require a prime and positive cyclotomic indices. Exponent maps omit zero entries after normalization. Symbolic expression and verification functions require the optional SymPy backend. A collapse result retains every p-free obstruction orbit and raises when the caller demands a closed form that is not present.

Guarantees (E, P, B, K). Orbit decomposition and exponent-lattice relations are exact. When no obstruction remains, the returned finite cyclotomic quotient is an exact formal collapse of the local Mahler product. Symbolic verification checks the declared relation rather than discovering a new one. Runtime is linear in the number of represented factors apart from optional symbolic simplification.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_cartier_padic.py` and `tests/test_generating_block13.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · pointed_subindex_polynomial

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.pointed_subindex_polynomial`. Reflected implementation `komorebi_math.generating.bell.pointed_subindex_polynomial`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-BELL`.

Manifest signature (s).

```
(index: 'int', prime: 'int') -> 'tuple[int, ...]'
```

Definition. Return the grouped left side of the pointed subindex identity. The coefficient of `u**j` is `sum binomial(n-1,m-1)` modulo `prime`, over positive digitwise subindices `m` with digit sum `j+1`.

Contract (D, C, H, R, X). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (E, P, B, K). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · polynomial_cartier

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.polynomial_cartier`. Reflected implementation `komorebi_math.generating.cartier.polynomial_cartier`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (s).

```
(polynomial: 'Sequence[int]', digit: 'int', prime: 'int') -> 'tuple[int, ...]'
```

Definition. Apply `Lambda_digit` to a polynomial modulo `prime`.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · polynomial_mask_coboundary

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.polynomial_mask_coboundary`. Reflected implementation `komorebi_math.generating.masks.polynomial_mask_coboundary`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (s).

```
(candidate: 'Iterable[Scalar]', radix: 'int', degree: 'int | None' = None) -> 'tuple[Fraction, ...]'
```

Definition. Return the mask `Q(z)/Q(z**radix)` of a declared polynomial unit.

Contract (D, C, H, R, X). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (E, P, B, K). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `polynomial_multiply_mod`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.polynomial_multiply_mod`. Reflected implementation `komorebi_math.generating.cartier.polynomial_multiply_mod`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(left: 'Sequence[int]', right: 'Sequence[int]', modulus: 'int') -> 'tuple[int, ...]'
```

Definition. Multiply coefficient tuples modulo `modulus`.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `polynomial_power_mod`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.polynomial_power_mod`. Reflected implementation `komorebi_math.generating.cartier.polynomial_power_mod`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CARTIER`.

Manifest signature (`s`).

```
(polynomial: 'Sequence[int]', exponent: 'int', modulus: 'int') -> 'tuple[int, ...]'
```

Definition. Raise a polynomial to a nonnegative power modulo `modulus`.

Contract (`D, C, H, R, X`). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (`E, P, B, K`). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · q_binomial_support

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.q_binomial_support`. Reflected implementation `komorebi_math.generating.q_kummer.q_binomial_support`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-QKUMMER`.

Manifest signature (s).

```
(index: 'int', base: 'int', prime: 'int', exponent: 'int', power: 'int' = 1) -> 'tuple[int, ...]'
```

Definition. Return subindices surviving in `GaussianBinomial**power mod p**exponent`.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · q_binomial_valuation_decomposition

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.q_binomial_valuation_decomposition`. Reflected implementation `komorebi_math.generating.q_kummer.q_binomial_valuation_decomposition`. The same runtime object is also exported as `komorebi_math.q_binomial_valuation_decomposition`. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-QKUMMER`.

Manifest signature (s).

```
(index: 'int', subindex: 'int', base: 'int', prime: 'int') -> 'QKummerDecomposition'
```

Definition. Return the exact mixed-radix valuation decomposition. If `prime` divides `base`, every Gaussian binomial is a unit modulo `prime` and the valuation is zero. For an odd prime coprime to `base`, the block length is `ord_prime(base)` and the usual order-block formula applies. For `prime == 2` and odd `base`, the block length is two and the lift constant is `v_2(base + 1)`.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · q_binomial_valuation_direct

Identity (q, a, t, k). Public research manifest route komorebi_math.generating.q_binomial_valuation_direct. Reflected implementation komorebi_math.generating.q_kummer.q_binomial_valuation_direct. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by [RESEARCH] policy pre-beta-additive. Manifest kind function. Profile C3-ARITH-QKUMMER.

Manifest signature (s).

```
(index: 'int', subindex: 'int', base: 'int', prime: 'int') -> 'int'
```

Definition. Compute the valuation directly from the integer Gaussian binomial.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_generating_cartier_padic.py. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · q_factorial

Identity (q, a, t, k). Public research manifest route komorebi_math.generating.q_factorial. Reflected implementation komorebi_math.generating.q_kummer.q_factorial. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by [RESEARCH] policy pre-beta-additive. Manifest kind function. Profile C3-ARITH-QKUMMER.

Manifest signature (s).

```
(index: 'int', base: 'int') -> 'int'
```

Definition. Return the integer q-factorial.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_generating_cartier_padic.py. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · q_integer

Identity (q, a, t, k). Public research manifest route komorebi_math.generating.q_integer. Reflected implementation komorebi_math.generating.q_kummer.q_integer. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by [RESEARCH] policy pre-beta-additive. Manifest kind function. Profile C3-ARITH-QKUMMER.

Manifest signature (s).

```
(index: 'int', base: 'int') -> 'int'
```

Definition. Return the integer q-analogue [index]_base.

Contract (D, C, H, R, X). The q-analogue routines require nonnegative indices, a valid subindex, an integer base, and a prime that does not violate the stated denominator or multiplicative-order conditions. Valuation decomposition requires a positive power and exponent where present. Support enumeration is finite and may be bounded by an explicit resource contract.

Guarantees (E, P, B, K). q-integers, q-factorials, Gaussian binomials, direct valuations, mixed-radix decompositions, and support sets are computed with exact integers. The decomposition records all factors used to reconstruct the valuation. Large Gaussian binomials can grow rapidly in bit length, so direct verification is bounded even when the structural decomposition remains compact.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_generating_cartier_padic.py. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · rational_mask_coefficients_mod_prime

Identity (q, a, t, k). Public research manifest route komorebi_math.generating.rational_mask_coefficients_mod_prime. Reflected implementation komorebi_math.generating.cartier.rational_mask_coefficients_mod_prime. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by [RESEARCH] policy pre-beta-additive. Manifest kind function. Profile C3-ARITH-CARTIER.

Manifest signature (s).

```
(numerator: 'Sequence[int]', denominator: 'Sequence[int]', prime: 'int', count: 'int') -> 'tuple[int, ...]'
```

Definition. Return the first count coefficients of the Mahler solution modulo prime.

Contract (D, C, H, R, X). Polynomial operations require a modulus of at least two. Cartier operators and rational-mask compilers require a prime, a valid digit, compatible nonzero constant coefficients, and explicit state or degree budgets. Automata read least-significant-first prime digits. Minimization preserves output behavior on the compiled finite-state machine. Certificate routines reject mismatched transition systems or coefficient prefixes.

Guarantees (E, P, B, K). Polynomial arithmetic, Cartier transitions, automaton outputs, and linear representations are exact modulo the selected prime. State bounds are finite compilation bounds rather than asymptotic minimality claims. Rational-mask coefficient generation and automaton evaluation agree on the checked prefix. Complexity is polynomial in polynomial degree and compiled state count, with minimization depending on partition refinement over the full transition table.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is tests/test_generating_cartier_padic.py. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · scan_residue_lanes

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.scan_residue_lanes`. Reflected implementation `komorebi_math.generating.congruences.scan_residue_lanes`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(values: 'Sequence[int]', *, modulus: 'int', lane_modulus: 'int', minimum_terms: 'int' = 8) ->
    ↪  'tuple[ResidueLaneFinding, ...]'
```

Definition. Find residue lanes that are constant modulo `modulus` on the prefix.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · search_decimation_relation

Identity (q, a, t, k). Public research manifest route `komorebi_math.generating.search_decimation_relation`. Reflected implementation `komorebi_math.generating.congruences.search_decimation_relation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CONGRUENCE`.

Manifest signature (s).

```
(values: 'Sequence[int]', *, prime: 'int', residue: 'int', max_order: 'int' = 8, holdout: 'int' = 12) ->
    ↪  'DecimationRelation | None'
```

Definition. Search `a[p*n+r]=sum_j c_j a[n+j] (mod p)`.

Contract (D, C, H, R, X). Congruence audits accept finite prefixes, a valid prime or modulus, and explicit index, order, degree, or lane bounds. Rational valuations require denominators that are meaningful for the selected prime. Recurrence discovery and decimation search operate only within the declared finite model class. An empty or insufficient prefix returns an empty result or no candidate according to the individual signature.

Guarantees (E, P, B, K). Every reported residue, valuation, recurrence, lane, or failure tuple is computed exactly on the supplied finite range. A passing audit is evidence for that range and is not an unbounded theorem by itself. Berlekamp-Massey is exact over the selected prime field. Search cost grows with prefix length, lane count, recurrence order, and coefficient search space.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27.

C.3B · `solve_polynomial_coboundary`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.solve_polynomial_coboundary`. Reflected implementation `komorebi_math.generating.masks.solve_polynomial_coboundary`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(numerator: 'Iterable[Scalar]', denominator: 'Iterable[Scalar]', radix: 'int', degree_bound: 'int', *, budget:
    ↪ 'GeneratingBudget' = GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000,
    ↪ maximum_matrix_dimension=4096, maximum_reachable_states=100000, maximum_local_combinations=1000000,
    ↪ maximum_modulus=2000000, maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) ->
    ↪ 'PolynomialCoboundaryResult'
```

Definition. Solve `B(z)Q(z)=A(z)Q(z**radix)` over the rationals.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.3B · `verify_cyclotomic_coboundary`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.verify_cyclotomic_coboundary`. Reflected implementation `komorebi_math.generating.cyclotomic.verify_cyclotomic_coboundary`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CYCLOTOMIC`.

Manifest signature (`s`).

```
(collapse: 'CyclotomicCollapse') -> 'bool'
```

Definition. Symbolically verify the closed form when the obstruction vanishes.

Contract (`D, C, H, R, X`). Cyclotomic routines require a prime and positive cyclotomic indices. Exponent maps omit zero entries after normalization. Symbolic expression and verification functions require the optional SymPy backend. A collapse result retains every p-free obstruction orbit and raises when the caller demands a closed form that is not present.

Guarantees (`E, P, B, K`). Orbit decomposition and exponent-lattice relations are exact. When no obstruction remains, the returned finite cyclotomic quotient is an exact formal collapse of the local Mahler product. Symbolic verification checks the declared relation rather than discovering a new one. Runtime is linear in the number of represented factors apart from optional symbolic simplification.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_cartier_padic.py` and `tests/test_generating_block13.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite cer-

tificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `verify_cyclotomic_exponent_relation`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.verify_cyclotomic_exponent_relation`. Reflected implementation `komorebi_math.generating.cyclotomic.verify_cyclotomic_exponent_relation`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-CYCLOTOMIC`.

Manifest signature (`s`).

```
(collapse: 'CyclotomicCollapse') -> 'bool'
```

Definition. Verify `R=Q/Q(z**p)` directly in the cyclotomic divisor lattice.

Contract (`D, C, H, R, X`). Cyclotomic routines require a prime and positive cyclotomic indices. Exponent maps omit zero entries after normalization. Symbolic expression and verification functions require the optional SymPy backend. A collapse result retains every p-free obstruction orbit and raises when the caller demands a closed form that is not present.

Guarantees (`E, P, B, K`). Orbit decomposition and exponent-lattice relations are exact. When no obstruction remains, the returned finite cyclotomic quotient is an exact formal collapse of the local Mahler product. Symbolic verification checks the declared relation rather than discovering a new one. Runtime is linear in the number of represented factors apart from optional symbolic simplification.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_cartier_padic.py` and `tests/test_generating_block13.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 26.

C.3B · `weighted_bell_digit_reduction`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.weighted_bell_digit_reduction`. Reflected implementation `komorebi_math.generating.bell.weighted_bell_digit_reduction`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-BELL`.

Manifest signature (`s`).

```
(index: 'int', prime: 'int', factorial_power: 'int', digit_weights: 'Iterable[int]', *, budget: 'GeneratingBudget'
    ↪ = GeneratingBudget(maximum_degree=100000, maximum_coefficient_bits=4000000, maximum_matrix_dimension=4096,
    ↪ maximum_reachable_states=100000, maximum_local_combinations=1000000, maximum_modulus=2000000,
    ↪ maximum_serialized_bytes=67108864, maximum_recursion_depth=1000)) -> 'BellDigitReduction'
```

Definition. Compute the weighted Bell digit-sum reduction at one index.

Contract (`D, C, H, R, X`). Bell reductions require a prime, a nonnegative index, and valid factorial-power or weight data. Automata consume base-prime digits in the order stated by each method. Period bounds and pointed-subindex identities are finite arithmetic contracts. Weighted reductions require enough local weights for the requested computation. Resource budgets cap explicit polynomial and state construction.

Guarantees (`E, P, B, K`). The returned reductions, parity values, residue automata, and pointed polynomial certificates are exact modulo the declared prime. A certificate records the finite comparison it performed. The period bound is an upper bound, not a minimal-period claim. Direct polynomial construction can grow with the digit sum or index, while automaton evaluation is linear in the number of input digits.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_foundation.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite

certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 22, 24, and 26.

C.3B · `zero_borrow_count`

Identity (`q, a, t, k`). Public research manifest route `komorebi_math.generating.zero_borrow_count`. Reflected implementation `komorebi_math.generating.masks.zero_borrow_count`. In the reference manifest, this symbol is exported only from the generating namespace. The generating route is governed by `[RESEARCH]` policy `pre-beta-additive`. Manifest kind `function`. Profile `C3-ARITH-MASK`.

Manifest signature (`s`).

```
(index: 'int', prime: 'int') -> 'int'
```

Definition. Return the exact number of no-borrow subindices.

Contract (`D, C, H, R, X`). Inputs describe a finite local mask, a radix of at least two, and an explicit truncation, modulus, exponent, or resource budget as required by the operation. Unit-series routines require a valid constant coefficient. Prime-power support routines require a prime and positive exponent. Carry plans validate every state and local index before allocation. Bounded solvers return a negative result when the declared search space contains no solution.

Guarantees (`E, P, B, K`). Finite coefficient identities, carry matrices, support layers, and polynomial certificates use exact integer or rational arithmetic. Analytic approximations separate the computed product from a stated tail bound. A finite functional equation or algebraic certificate applies only through its recorded degree. Direct mask products are at least quadratic in the truncation boundary, while carry-state plans depend on the explicit state dimension and budget.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_generating_block13.py` and `tests/test_generating_cartier_padic.py`. The independent verifier for arithmetic checks the relevant exact arithmetic identities, compiled representations, finite certificates, rejection paths, and runtime ownership. The source validator for arithmetic checks the exact signature, implementation identity, facade routes, record counts, and unique anchor. See Chapters 24 through 27 and 64.

C.4 `komorebi_math.signals`: 171 entries

C.4A Windows, convolution, filtering, resampling, and spectral transforms: 80 entries

This section establishes the finite signal-processing substrate used by the remaining wavelet, recovery, and packet contracts. It fixes the public type vocabularies, window and overlap conventions, direct and FFT convolution, linear filtering, rational resampling, framing, STFT analysis and synthesis, spectrogram scaling, power spectra, cross spectra, and bounded streaming state. The contracts are numerical and finite. They distinguish exact shape and index conventions from floating-point equality certificates.

Contract family	Cards
Shared type vocabularies and domain status	17
Windows and overlap lattices	6
Finite convolution and block matrices	9
FIR design and streaming FIR	11
Recursive FIR and IIR execution	6
Rational resampling	10
Framing, STFT, inverse STFT, and spectrograms	8
Periodograms, Welch estimates, and cross spectra	6
Incremental STFT execution	3
FFT and overlap-add convolution	4
Total	**80**

The boundary is explicit. A certificate checks one finite array identity, reconstruction, overlap law, stability predicate, or batch-versus-streaming comparison under the stored tolerance. Spectral estimates describe the supplied finite records and selected normalization. They do not infer an unobserved stochastic process. Window, framing, padding, sidedness, detrending, cropping, and rate-conversion conventions remain part of the public contract.

C.4A · `AdaptiveMethod`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.AdaptiveMethod`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (`s`).

```
(*args, **kwargs)
```

Definition. Literal method vocabulary accepted by adaptive filters: `lms`, `nlms`, or `rls`.

Contract (`D, C, H, R, X`). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (`E, P, B, K`). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · `BiquadKind`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.BiquadKind`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (`s`).

```
(*args, **kwargs)
```

Definition. Literal biquad design vocabulary: `lowpass`, `highpass`, `bandpass`, `notch`, or `allpass`.

Contract (`D, C, H, R, X`). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (`E, P, B, K`). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · BoundaryMode

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.BoundaryMode`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal framing boundary vocabulary: `zeros`, `reflect`, `edge`, or `none`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · ConvolutionMode

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.ConvolutionMode`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal finite convolution vocabulary: `full`, `same`, `valid`, or `circular`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · CrossSpectrum

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.CrossSpectrum`. Reflected implementation `komorebi_math.signals.spectral.CrossSpectrum`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SPECTRAL`.

Manifest signature (s).

```
(frequencies: 'np.ndarray', cross_power: 'np.ndarray', input_power: 'np.ndarray', output_power: 'np.ndarray',
   ↪ coherence: 'np.ndarray', transfer_h1: 'np.ndarray', sample_rate: 'float', scaling: 'SpectralScaling',
   ↪ onesided: 'bool', fft_length: 'int', segment_count: 'int', certificate: 'Certificate') -> None
```

Definition. Averaged auto spectra, cross spectrum, coherence, and H1 transfer estimate.

Contract (D, C, H, R, X). Spectral estimators require finite one-dimensional records, a positive sample rate, a valid window and detrending mode, and compatible frame and overlap lengths. Cross spectra require equal-length inputs. One-sided output is reserved for real data. Regularization must be nonnegative and is applied explicitly where transfer ratios would otherwise be singular.

Guarantees (E, P, B, K). Parseval certificates compare the finite NumPy-normalized DFT energy identity. Periodogram and Welch records expose frequency resolution, dominant frequency, and integrated power under the chosen scaling. Cross-spectrum records contain auto spectra, cross spectrum, coherence, and the H1 estimate. Results are numerical finite estimates, not stochastic consistency theorems. FFT cost dominates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · DetrendMode

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.DetrendMode`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal detrending vocabulary for finite frames: `none` or `constant`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · FEATURE_KEY

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FEATURE_KEY`. Reflected implementation `builtins.str`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-DOMAIN-STATUS`.

Manifest signature (s).

```
null
```

Definition. The registry key `signals` used to query this domain's implementation status.

Contract (D, C, H, R, X). The feature key is the literal string `signals`. `status()` queries the package registry for that key and returns the registered `FeatureSpec`. The call does not run signal processing, import an optional accelerator, or qualify a backend.

Guarantees (E, P, B, K). The result is deterministic package metadata for the installed source tree. Lookup is constant-time in ordinary Python terms and makes no independent mathematical or numerical claim.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The domain registry path is exercised by the independent verifier for signal foundations. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 4, 31, and 72.

C.4A · FIRFilter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FIRFilter`. Reflected implementation `komorebi_math.signals.filtering.FIRFilter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FIR`.

Manifest signature (s).

```
(taps: 'np.ndarray', kind: 'FIRKind', cutoff: 'tuple[float, ...]', sample_rate: 'float' = 1.0, window_name: 'str'
   ↪  = 'custom', reference_frequency: 'float | None' = None, reference_gain: 'float' = 1.0) -> None
```

Definition. A finite linear-phase FIR design and its declared design metadata.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable. The principal public operations are `order`, `group_delay_samples`, `apply`, `response`, `certificate`.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · FIRKind

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FIRKind`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal FIR design vocabulary: `lowpass`, `highpass`, `bandpass`, or `bandstop`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · FIRMode

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FIRMode`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal FIR execution vocabulary: `causal`, `full`, `same`, or `valid`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · FilterOutput

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FilterOutput`. Reflected implementation `komorebi_math.signals.recursive.FilterOutput`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-RECURSIVE`.

Manifest signature (s).

```
(samples: 'np.ndarray', final_state: 'np.ndarray') -> None
```

Definition. Filtered samples paired with the final direct-form state.

Contract (D, C, H, R, X). Numerator and denominator coefficient arrays must be finite and nonempty, and the leading denominator coefficient must be nonzero. Initial state length must equal the normalized filter order. Biquad frequency and quality parameters must satisfy the documented physical range. Streaming execution uses one fixed normalized model until reset.

Guarantees (E, P, B, K). The implementation follows direct-form II transposed recursion after denominator normalization. Batch and chunked execution use the same recurrence and therefore agree to numerical precision. Pole-based stability certificates check the finite coefficient model rather than an external plant. Runtime is linear in sample count times filter order, with linear state storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · FinitePolyphaseKernel

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FinitePolyphaseKernel`. Reflected implementation `komorebi_math.signals.convolution.PolyphaseBlockMatrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `PolyphaseBlockMatrix` resolves to the same runtime object. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(blocks: 'tuple[tuple[np.ndarray, ...], ...]', order: 'int', input_length: 'int', output_length: 'int') -> None
```

Definition. Finite packet blocks of a convolution matrix.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · FrameBatch

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FrameBatch`. Reflected implementation `komorebi_math.signals.time_frequency.FrameBatch`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (s).

```
(frames: 'np.ndarray', starts: 'np.ndarray', original_length: 'int', frame_length: 'int', hop_length: 'int',
    ↪ pad_left: 'int', pad_right: 'int', boundary: 'BoundaryMode') -> None
```

Definition. A deterministic finite framing of a one-dimensional signal.

Contract (D, C, H, R, X). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile. The principal public operations are `frame_count`, `padded_length`, `covered_length`, `certificate`.

Guarantees (E, P, B, K). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · FrequencyResponse

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.FrequencyResponse`. Reflected implementation `komorebi_math.signals.filtering.FrequencyResponse`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FIR`.

Manifest signature (s).

```
(frequencies: 'np.ndarray', response: 'np.ndarray', sample_rate: 'float') -> None
```

Definition. Sampled FIR transfer values on a physical frequency grid.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable. The principal public operations are `magnitude`, `phase`, `magnitude_db`.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · LinearFilter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.LinearFilter`. Reflected implementation `komorebi_math.signals.recursive.LinearFilter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-RECURSIVE`.

Manifest signature (s).

```
(numerator: 'Any', denominator: 'Any' = (1.0,)) -> 'None'
```

Definition. Normalized causal FIR/IIR filter in direct-form II transposed form.

Contract (D, C, H, R, X). Numerator and denominator coefficient arrays must be finite and nonempty, and the leading denominator coefficient must be nonzero. Initial state length must equal the normalized filter order. Biquad frequency and quality parameters must satisfy the documented physical range. Streaming execution uses one fixed normalized model until reset. The principal public operations are `order`, `zeros`, `poles`, `process`, `response`, `stability_certificate`.

Guarantees (E, P, B, K). The implementation follows direct-form II transposed recursion after denominator normalization. Batch and chunked execution use the same recurrence and therefore agree to numerical precision. Pole-based stability certificates check the finite coefficient model rather than an external plant. Runtime is linear in sample count times filter order, with linear state storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · OverlapAddConvolver

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.OverlapAddConvolver`. Reflected implementation `komorebi_math.signals.fft_convolution.OverlapAddConvolver`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FFT-CONVOLUTION`.

Manifest signature (s).

```
(kernel: 'np.ndarray', block_length: 'int' = 1024) -> None
```

Definition. Stateful bounded-input-buffer FFT overlap-add convolver.

Contract (D, C, H, R, X). Signal and kernel arrays must be finite, one-dimensional, and nonempty. FFT and overlap-add execution require a positive block length. The output mode applies the same finite cropping convention as direct convolution. A stateful convolver accepts chunks until `flush()`, emits the remaining tail once, and requires `reset()` before reuse after finalization. The principal public operations are `buffered_samples`, `process`, `flush`, `reset`.

Guarantees (E, P, B, K). Zero-padded FFT convolution and bounded-buffer overlap-add agree with direct finite convolution to numerical precision. The certified wrapper records that comparison. FFT execution reduces the asymptotic cost for long records and kernels to blockwise transform cost, while the stateful object stores the kernel spectrum, overlap tail, and one bounded input buffer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · PacketPath

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PacketPath`. Reflected implementation `types.UnionType`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
null
```

Definition. Wavelet packet path identifier represented by a string or a tuple of integer branch indices.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · PolyphaseBlockMatrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PolyphaseBlockMatrix`. Reflected implementation `komorebi_math.signals.convolution.PolyphaseBlockMatrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `FinitePolyphaseKernel` resolves to the same runtime object. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(blocks: 'tuple[tuple[np.ndarray, ...], ...]', order: 'int', input_length: 'int', output_length: 'int') -> None
```

Definition. Finite packet blocks of a convolution matrix.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · PolyphaseConvolution

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PolyphaseConvolution`. Reflected implementation `komorebi_math.signals.convolution.PolyphaseConvolution`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(kernel: 'np.ndarray', input_length: 'int', order: 'int', mode: 'ConvolutionMode' = 'full') -> None
```

Definition. Exact packet block representation of a finite convolution operator.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets. The principal public operations are `matrix`, `output_length`, `source_indices`, `target_indices`, `blocks`, `apply_coordinates`, `apply`, `certificate`.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · PowerSpectrum

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.PowerSpectrum`. Reflected implementation `komorebi_math.signals.spectral.PowerSpectrum`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-SPECTRAL`.

Manifest signature (s).

```
(frequencies: 'np.ndarray', power: 'np.ndarray', sample_rate: 'float', scaling: 'SpectralScaling', onesided:
    ↪ 'bool', fft_length: 'int', segment_count: 'int', frame_length: 'int', hop_length: 'int', window:
    ↪ 'np.ndarray', method: 'str', certificate: 'Certificate') -> None
```

Definition. A finite periodogram or averaged power spectral estimate.

Contract (D, C, H, R, X). Spectral estimators require finite one-dimensional records, a positive sample rate, a valid window and detrending mode, and compatible frame and overlap lengths. Cross spectra require equal-length inputs. One-sided output is reserved for real data. Regularization must be nonnegative and is applied explicitly where transfer ratios would otherwise be singular. The principal public operations are `frequency_resolution`, `dominant_frequency`, `integrated_power`.

Guarantees (E, P, B, K). Parseval certificates compare the finite NumPy-normalized DFT energy identity. Periodogram and Welch records expose frequency resolution, dominant frequency, and integrated power under the chosen scaling. Cross-spectrum records contain auto spectra, cross spectrum, coherence, and the H1 estimate. Results are numerical finite estimates, not stochastic consistency theorems. FFT cost dominates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · RationalResamplingPlan

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.RationalResamplingPlan`. Reflected implementation `komorebi_math.signals.resampling.RationalResamplingPlan`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(up: 'int', down: 'int', taps: 'np.ndarray') -> None
```

Definition. A centered zero-extension rational-resampling plan.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel. The principal public operations are `delay`, `polyphase_components`, `output_length`, `apply`, `explicit_reference`, `certificate`.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · ResamplingResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.ResamplingResult`. Reflected implementation `komorebi_math.signals.resampling.ResamplingResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'np.ndarray', plan: 'RationalResamplingPlan', input_length: 'int', certificate: 'Certificate') -> None
```

Definition. A finite rationally resampled signal paired with its execution plan and certificate.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · STFTResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.STFTResult`. Reflected implementation `komorebi_math.signals.time_frequency.STFTResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (s).

```
(coefficients: 'np.ndarray', frequencies: 'np.ndarray', times: 'np.ndarray', sample_rate: 'float', frame_length:
   ↪ 'int', hop_length: 'int', fft_length: 'int', analysis_window: 'np.ndarray', original_length: 'int',
   ↪ pad_left: 'int', pad_right: 'int', onesided: 'bool', boundary: 'BoundaryMode', detrend: 'DetrendMode') ->
   ↪ None
```

Definition. Finite short-time Fourier coefficients and complete synthesis metadata.

Contract (D, C, H, R, X). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile. The principal public operations are `frame_count`, `inverse`, `roundtrip_certificate`.

Guarantees (E, P, B, K). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · SpectralAverage

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.SpectralAverage`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal Welch averaging vocabulary: `mean` or `median`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · SpectralScaling

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.SpectralScaling`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal power spectrum scaling vocabulary: `density` or `spectrum`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · SpectrogramResult

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.SpectrogramResult`. Reflected implementation `komorebi_math.signals.time_frequency.SpectrogramResult`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (s).

```
(values: 'np.ndarray', frequencies: 'np.ndarray', times: 'np.ndarray', scaling: 'SpectrogramScaling', sample_rate:
    ↪ 'float', transform: 'STFTResult') -> None
```

Definition. A finite time-frequency magnitude or power representation.

Contract (D, C, H, R, X). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile.

Guarantees (E, P, B, K). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · SpectrogramScaling

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.SpectrogramScaling`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal spectrogram scaling vocabulary: `density`, `spectrum`, `magnitude`, or `power`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · StreamingFIR

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.StreamingFIR`. Reflected implementation `komorebi_math.signals.filtering.StreamingFIR`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-FIR`.

Manifest signature (s).

```
(taps: 'Any') -> 'None'
```

Definition. Stateful causal FIR execution with bounded input history.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable. The principal public operations are `process`, `flush`, `reset`.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · StreamingLinearFilter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.StreamingLinearFilter`. Reflected implementation `komorebi_math.signals.recursive.StreamingLinearFilter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-RECURSIVE`.

Manifest signature (s).

```
(filter: 'LinearFilter') -> None
```

Definition. Mutable chunked execution of one finite-order linear filter.

Contract (D, C, H, R, X). Numerator and denominator coefficient arrays must be finite and nonempty, and the leading denominator coefficient must be nonzero. Initial state length must equal the normalized filter order. Biquad frequency and quality parameters must satisfy the documented physical range. Streaming execution uses one fixed normalized model until reset. The principal public operations are `process`, `reset`.

Guarantees (E, P, B, K). The implementation follows direct-form II transposed recursion after denominator normalization. Batch and chunked execution use the same recurrence and therefore agree to numerical precision. Pole-based stability certificates check the finite coefficient model rather than an external plant. Runtime is linear in sample count times filter order, with linear state storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · StreamingSTFT

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.StreamingSTFT`. Reflected implementation `komorebi_math.signals.streaming.StreamingSTFT`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-STREAMING-STFT`.

Manifest signature (s).

```
(frame_length: 'int' = 256, hop_length: 'int | None' = None, fft_length: 'int | None' = None, window: 'WindowSpec'
   ↪  = 'hann', sample_rate: 'float' = 1.0, onesided: 'bool' = True, detrend: 'DetrendMode' = 'none') -> None
```

Definition. Incremental finite STFT analysis with bounded overlap memory.

Contract (D, C, H, R, X). A streaming STFT instance fixes its frame, hop, FFT, window, boundary, and sidedness configuration at construction. Chunks must be one-dimensional and compatible with the selected real or complex mode. `flush()` finalizes optional end padding. Processing after finalization is rejected until `reset()` is called. The convenience wrapper requires chunk sizes that cover the supplied record exactly. The principal public operations are `frequencies`, `buffered_samples`, `total_samples`, `reset`, `process`, `flush`.

Guarantees (E, P, B, K). The processor stores only the unresolved overlap and framing state. Emitted frames are consecutive and use the same transform convention as batch `stft()`. The wrapper certificate compares concatenated streaming output with the matching batch transform to numerical tolerance. Work per emitted frame is one FFT plus bounded buffer movement.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · StreamingSTFTBatch

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.StreamingSTFTBatch`. Reflected implementation `komorebi_math.signals.streaming.StreamingSTFTBatch`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-STREAMING-STFT`.

Manifest signature (s).

```
(coefficients: 'np.ndarray', frequencies: 'np.ndarray', times: 'np.ndarray', starts: 'np.ndarray', sample_rate:
   ↪  'float', frame_length: 'int', hop_length: 'int', fft_length: 'int', onesided: 'bool') -> None
```

Definition. Zero or more consecutive STFT frames emitted by one streaming operation.

Contract (D, C, H, R, X). A streaming STFT instance fixes its frame, hop, FFT, window, boundary, and sidedness configuration at construction. Chunks must be one-dimensional and compatible with the selected real or complex mode. `flush()` finalizes optional end padding. Processing after finalization is rejected until `reset()` is called. The convenience wrapper requires chunk sizes that cover the supplied record exactly. The principal public operations are `frame_count`.

Guarantees (E, P, B, K). The processor stores only the unresolved overlap and framing state. Emitted frames are consecutive and use the same transform convention as batch `stft()`. The wrapper certificate compares concatenated streaming output with the matching batch transform to numerical tolerance. Work per emitted frame is one FFT plus bounded buffer movement.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_denoise_streaming.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · ThresholdMode

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.ThresholdMode`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal coefficient thresholding vocabulary: `soft`, `hard`, or `garrote`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · ThresholdRule

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.ThresholdRule`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal threshold selection vocabulary: `universal`, `sure`, or `fixed`.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · WindowMetrics

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.WindowMetrics`. Reflected implementation `komorebi_math.signals.windows.WindowMetrics`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `class`. Profile `C4-WINDOWS`.

Manifest signature (s).

```
(length: 'int', coherent_gain: 'float', power_gain: 'float', equivalent_noise_bandwidth_bins: 'float',
    ↪ equivalent_noise_bandwidth_hz: 'float') -> None
```

Definition. Finite gain and equivalent-noise-bandwidth diagnostics for a window.

Contract (D, C, H, R, X). Window length and hop values must be positive integers. Parameterized Kaiser and Tukey windows validate their finite parameters. An explicit array must be one-dimensional and have exactly the requested length. Overlap certificates require a compatible shift lattice. Canonical dual construction returns an invalid result when the overlap profile contains a zero.

Guarantees (E, P, B, K). Named windows, gain metrics, overlap profiles, and dual windows are deterministic finite NumPy computations. Certificates state finite overlap or constant-overlap identities to a declared tolerance. Window construction and metric evaluation are linear in window length. Overlap profiles also scale with the number of hop residues.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 31 and Chapter 32.

C.4A · WindowName

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.WindowName`. Reflected implementation `typing.Literal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Literal named-window vocabulary for boxcar, rectangular, Hann, Hamming, Blackman, Bartlett, Kaiser, and Tukey windows.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · WindowSpec

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.WindowSpec`. Reflected implementation `typing.Union`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `data`. Profile `C4-SIGNAL-TYPES`.

Manifest signature (s).

```
(*args, **kwargs)
```

Definition. Accepted window specification union: a supported name, a string alias, a parameter tuple, or an explicit NumPy array.

Contract (D, C, H, R, X). These exports are annotation vocabularies rather than executable validators. Callers should pass one of the listed literal values or one of the accepted union members. The consuming function performs the runtime shape, range, and compatibility checks. A type alias may be imported and inspected, but it is not a substitute for invoking the associated signal operation.

Guarantees (E, P, B, K). The aliases deterministically describe the accepted public vocabulary in the reference manifest. They make no numerical claim and allocate no signal state. Import and annotation lookup are constant-time in ordinary Python terms. Behavioral guarantees belong to the functions and records that consume each alias.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block12_windows_time_frequency.py` and `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 through 36 and 72.

C.4A · canonical_dual_window

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.canonical_dual_window`. Reflected implementation `komorebi_math.signals.windows.canonical_dual_window`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WINDOWS`.

Manifest signature (s).

```
(window: 'Any', hop_length: 'int', *, tolerance: 'float' = 1e-12) -> 'ComputationResult[np.ndarray]'
```

Definition. Return the canonical synthesis window for the declared shift lattice.

Contract (D, C, H, R, X). Window length and hop values must be positive integers. Parameterized Kaiser and Tukey windows validate their finite parameters. An explicit array must be one-dimensional and have exactly the requested length. Overlap certificates require a compatible shift lattice. Canonical dual construction returns an invalid result when the overlap profile contains a zero.

Guarantees (E, P, B, K). Named windows, gain metrics, overlap profiles, and dual windows are deterministic finite NumPy computations. Certificates state finite overlap or constant-overlap identities to a declared tolerance. Window construction and metric evaluation are linear in window length. Overlap profiles also scale with the number of hop residues.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 31 and Chapter 32.

C.4A · certified_overlap_add_convolve

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.certified_overlap_add_convolve`. Reflected implementation `komorebi_math.signals.fft_convolution.certified_overlap_add_convolve`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FFT-CONVOLUTION`.

Manifest signature (s).

```
(signal: 'Any', kernel: 'Any', *, block_length: 'int' = 1024, mode: 'FIRMode' = 'full', tolerance: 'float' = 1e-11)
   ↪  -> 'ComputationResult[np.ndarray]'
```

Definition. Return overlap-add output with a direct-convolution equality certificate.

Contract (D, C, H, R, X). Signal and kernel arrays must be finite, one-dimensional, and nonempty. FFT and overlap-add execution require a positive block length. The output mode applies the same finite cropping convention as direct convolution. A stateful convolver accepts chunks until `flush()`, emits the remaining tail once, and requires `reset()` before reuse after finalization.

Guarantees (E, P, B, K). Zero-padded FFT convolution and bounded-buffer overlap-add agree with direct finite convolution to numerical precision. The certified wrapper records that comparison. FFT execution reduces the asymptotic cost for long records and kernels to blockwise transform cost, while the stateful object stores the kernel spectrum, overlap tail, and one bounded input buffer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · convolution_matrix

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.convolution_matrix`. Reflected implementation `komorebi_math.signals.convolution.convolution_matrix`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(kernel: 'Any', input_length: 'int', *, mode: 'ConvolutionMode' = 'full') -> 'np.ndarray'
```

Definition. Return the matrix implementing a finite convolution convention.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · convolution_output_length

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.convolution_output_length`. Reflected implementation `komorebi_math.signals.convolution.convolution_output_length`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(input_length: 'int', kernel_length: 'int', mode: 'ConvolutionMode') -> 'int'
```

Definition. Return the finite one dimensional convolution output length.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · convolve_signal

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.convolve_signal`. Reflected implementation `komorebi_math.signals.convolution.convolve_signal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(signal: 'Any', kernel: 'Any', *, mode: 'ConvolutionMode' = 'full') -> 'np.ndarray'
```

Definition. Apply the declared finite convolution convention.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · cross_spectrum

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.cross_spectrum`. Reflected implementation `komorebi_math.signals.spectral.cross_spectrum`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-SPECTRAL`.

Manifest signature (s).

```
(input_signal: 'Any', output_signal: 'Any', *, sample_rate: 'float' = 1.0, frame_length: 'int' = 256, hop_length:
    ↪ 'int | None' = None, fft_length: 'int | None' = None, window: 'WindowSpec' = 'hann', detrend: 'DetrendMode'
    ↪ = 'constant', scaling: 'SpectralScaling' = 'density', average: 'SpectralAverage' = 'mean', onesided: 'bool |
    ↪ None' = None, regularization: 'float' = 0.0) -> 'CrossSpectrum'
```

Definition. Estimate paired auto spectra, cross spectrum, coherence, and H1 transfer.

Contract (D, C, H, R, X). Spectral estimators require finite one-dimensional records, a positive sample rate, a valid window and detrending mode, and compatible frame and overlap lengths. Cross spectra require equal-length inputs. One-sided output is reserved for real data. Regularization must be nonnegative and is applied explicitly where transfer ratios would otherwise be singular.

Guarantees (E, P, B, K). Parseval certificates compare the finite NumPy-normalized DFT energy identity. Periodogram and Welch records expose frequency resolution, dominant frequency, and integrated power under the chosen scaling. Cross-spectrum records contain auto spectra, cross spectrum, coherence, and the H1 estimate. Results are numerical finite estimates, not stochastic consistency theorems. FFT cost dominates.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 32.

C.4A · decimate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.decimate`. Reflected implementation `komorebi_math.signals.resampling.decimate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'Any', factor: 'int', *, num_taps: 'int | None' = None, window: 'WindowSpec' = ('kaiser', 8.0)) ->
    ↪ 'np.ndarray'
```

Definition. Low-pass filter and downsample a finite signal by an integer factor.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · design_bandpass

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_bandpass`. Reflected implementation `komorebi_math.signals.filtering.design_bandpass`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(cutoff: 'tuple[float, float]', **options: 'Any') -> 'FIRFilter'
```

Definition. Design a bandpass FIR filter.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · design_bandstop

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_bandstop`. Reflected implementation `komorebi_math.signals.filtering.design_bandstop`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(cutoff: 'tuple[float, float]', **options: 'Any') -> 'FIRFilter'
```

Definition. Design a bandstop FIR filter.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · design_biquad

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_biquad`. Reflected implementation `komorebi_math.signals.recursive.design_biquad`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RECURSIVE`.

Manifest signature (s).

```
(kind: 'BiquadKind', frequency: 'float', *, q: 'float' = np.float64(0.7071067811865475), sample_rate: 'float' =
    ↪ 1.0) -> 'LinearFilter'
```

Definition. Design a lowpass, highpass, bandpass, notch, or allpass biquad.

Contract (D, C, H, R, X). Numerator and denominator coefficient arrays must be finite and nonempty, and the leading denominator coefficient must be nonzero. Initial state length must equal the normalized filter order. Biquad frequency and quality parameters must satisfy the documented physical range. Streaming execution uses one fixed normalized model until reset.

Guarantees (E, P, B, K). The implementation follows direct-form II transposed recursion after denominator normalization. Batch and chunked execution use the same recurrence and therefore agree to numerical precision. Pole-based stability certificates check the finite coefficient model rather than an external plant. Runtime is linear in sample count times filter order, with linear state storage.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · design_fir

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_fir`. Reflected implementation `komorebi_math.signals.filtering.design_fir`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(kind: 'FIRKind', cutoff: 'float | tuple[float, float]', *, num_taps: 'int' = 101, sample_rate: 'float' = 1.0,
    ↪ window: 'WindowSpec' = 'hann', scale: 'bool' = True) -> 'FIRFilter'
```

Definition. Design a real linear-phase FIR filter by a windowed ideal impulse response.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · design_highpass

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_highpass`. Reflected implementation `komorebi_math.signals.filtering.design_highpass`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(cutoff: 'float', **options: 'Any') -> 'FIRFilter'
```

Definition. Design a highpass FIR filter.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · design_lowpass

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_lowpass`. Reflected implementation `komorebi_math.signals.filtering.design_lowpass`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(cutoff: 'float', **options: 'Any') -> 'FIRFilter'
```

Definition. Design a lowpass FIR filter.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

C.4A · design_resample_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.design_resample_filter`. Reflected implementation `komorebi_math.signals.resampling.design_resample_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(up: 'int', down: 'int', *, num_taps: 'int | None' = None, window: 'WindowSpec' = ('kaiser', 8.0)) -> 'np.ndarray'
```

Definition. Design the centered low-pass kernel used by rational resampling.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · downsample

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.downsample`. Reflected implementation `komorebi_math.signals.resampling.downsample`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'Any', factor: 'int', *, phase: 'int' = 0) -> 'np.ndarray'
```

Definition. Retain one residue class from a finite signal.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · fft_convolve

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.fft_convolve`. Reflected implementation `komorebi_math.signals.fft_convolution.fft_convolve`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FFT-CONVOLUTION`.

Manifest signature (s).

```
(signal: 'Any', kernel: 'Any', *, mode: 'FIRMode' = 'full') -> 'np.ndarray'
```

Definition. Compute finite linear convolution by a zero-padded FFT.

Contract (D, C, H, R, X). Signal and kernel arrays must be finite, one-dimensional, and nonempty. FFT and overlap-add execution require a positive block length. The output mode applies the same finite cropping convention as direct convolution. A stateful convolver accepts chunks until `flush()`, emits the remaining tail once, and requires `reset()` before reuse after finalization.

Guarantees (E, P, B, K). Zero-padded FFT convolution and bounded-buffer overlap-add agree with direct finite convolution to numerical precision. The certified wrapper records that comparison. FFT execution reduces the asymptotic cost for long records and kernels to blockwise transform cost, while the stateful object stores the kernel spectrum, overlap tail, and one bounded input buffer.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_recursive_fft.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · finite_polyphase_blocks

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.finite_polyphase_blocks`. Reflected implementation `komorebi_math.signals.convolution.finite_polyphase_blocks`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `finite_polyphase_filter_kernels` resolves to the same runtime object. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(kernel: 'Any', input_length: 'int', order: 'int', *, mode: 'ConvolutionMode' = 'full') -> 'PolyphaseBlockMatrix'
```

Definition. Return the exact finite packet blocks of a convolution operator.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test modules are `tests/test_block4_hardening.py` and `tests/test_signals_polyphase_filterbanks.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · finite_polyphase_filter_kernels

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.finite_polyphase_filter_kernels`. Reflected implementation `komorebi_math.signals.convolution.finite_polyphase_blocks`. No root, stable, or beta facade exports this domain-only name in the reference manifest. Within `komorebi_math.signals`, `finite_polyphase_blocks` resolves to the same runtime object. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-CONVOLUTION`.

Manifest signature (s).

```
(kernel: 'Any', input_length: 'int', order: 'int', *, mode: 'ConvolutionMode' = 'full') -> 'PolyphaseBlockMatrix'
```

Definition. Return the exact finite packet blocks of a convolution operator.

Contract (D, C, H, R, X). Signals and kernels are finite one-dimensional arrays, with nonempty inputs where convolution is required. The selected mode fixes the output convention. Circular convolution requires a compatible finite length. Matrix and polyphase constructors require positive dimensions and a positive packet order. Every block retains explicit source and target index sets.

Guarantees (E, P, B, K). The direct operator, matrix representation, and finite polyphase blocks implement the same declared finite convolution law up to the numerical behavior of the input dtype. Matrix construction exposes the full linear map and can require quadratic storage. Direct convolution scales with signal length times kernel length, while block application has the corresponding partitioned cost.

C.4A · fir_filter

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.fir_filter`. Reflected implementation `komorebi_math.signals.filtering.fir_filter`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(signal: 'Any', taps: 'Any', *, mode: 'FIRMode' = 'causal') -> 'np.ndarray'
```

Definition. Apply finite convolution with a signal-length-preserving `same` convention.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. C.4A · fir_frequency_response

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.fir_frequency_response`. Reflected implementation `komorebi_math.signals.filtering.fir_frequency_response`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-FIR`.

Manifest signature (s).

```
(taps: 'Any', *, points: 'int' = 512, sample_rate: 'float' = 1.0, whole: 'bool' = False) -> 'FrequencyResponse'
```

Definition. Evaluate a finite impulse response on an equally spaced frequency grid.

Contract (D, C, H, R, X). FIR design requires a positive odd tap count, a positive sample rate, and cutoff frequencies strictly inside the Nyquist interval. Band edges must be ordered. Filtering requires a finite nonempty signal and tap vector. The selected FIR mode fixes cropping. Streaming execution preserves only the bounded causal history and rejects processing after reaching a terminal state where applicable.

Guarantees (E, P, B, K). Windowed ideal-response designs are real and symmetric, with the documented normalization and group delay. Frequency responses are sampled finite Fourier sums. Streaming and batch causal FIR execution agree to numerical precision for the same dtype and chunk order. Direct filtering scales with sample count times tap count and stores tap-count history.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_spectral_filtering.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 33.

C.4A · `frame_signal`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.frame_signal`. Reflected implementation `komorebi_math.signals.time_frequency.frame_signal`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (`s`).

```
(signal: 'Any', frame_length: 'int', hop_length: 'int | None' = None, *, center: 'bool' = False, pad_end: 'bool' =
    ↪ False, boundary: 'BoundaryMode' = 'zeros') -> 'FrameBatch'
```

Definition. Split a finite signal into complete uniformly spaced frames.

Contract (`D, C, H, R, X`). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile.

Guarantees (`E, P, B, K`). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapters 31 and 32.

C.4A · `get_window`

Identity (`q, a, t, k`). Public research-manifest route `komorebi_math.signals.get_window`. Reflected implementation `komorebi_math.signals.windows.get_window`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-WINDOWS`.

Manifest signature (`s`).

```
(window: 'WindowSpec', length: 'int', *, periodic: 'bool' = True) -> 'np.ndarray'
```

Definition. Return a finite real window using an explicit periodic or symmetric convention.

Contract (`D, C, H, R, X`). Window length and hop values must be positive integers. Parameterized Kaiser and Tukey windows validate their finite parameters. An explicit array must be one-dimensional and have exactly the requested length. Overlap certificates require a compatible shift lattice. Canonical dual construction returns an invalid result when the overlap profile contains a zero.

Guarantees (`E, P, B, K`). Named windows, gain metrics, overlap profiles, and dual windows are deterministic finite NumPy computations. Certificates state finite overlap or constant-overlap identities to a declared tolerance. Window construction and metric evaluation are linear in window length. Overlap profiles also scale with the number of hop residues.

Evidence and links (`V, L`). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_windows_time_frequency.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 31 and Chapter 32.

C.4A · interpolate

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.interpolate`. Reflected implementation `komorebi_math.signals.resampling.interpolate`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-RESAMPLING`.

Manifest signature (s).

```
(signal: 'Any', factor: 'int', *, num_taps: 'int | None' = None, window: 'WindowSpec' = ('kaiser', 8.0)) ->
   ↪ 'np.ndarray'
```

Definition. Upsample and anti-image filter a finite signal by an integer factor.

Contract (D, C, H, R, X). Upsampling and downsampling factors must be positive integers. A downsampling phase must select a valid residue class. Rational plans reduce the rate ratio, use finite centered zero extension, and require a finite nonempty input. A supplied antialiasing kernel must satisfy the plan's finite shape and gain requirements. Default design uses an odd symmetric low-pass kernel.

Guarantees (E, P, B, K). The output length is exactly `ceil(input_length * up / down)`. Plan certificates compare polyphase execution with an explicit zero-insertion, convolution, delay, and decimation reference to numerical tolerance. Primitive upsampling and downsampling are exact array operations. Polyphase runtime scales with output length and the active taps per phase.

Evidence and links (V, L). The committed research manifest and runtime reflection audit identify this export. The focused test module is `tests/test_block12_resampling_adaptive.py`. The independent verifier for signal foundations checks the relevant finite identities, reference calculations, chunk invariance, rejection paths, and runtime ownership. The source validator for signal foundations checks the exact signature, implementation identity, signal facade, cumulative counts, and unique anchor. See Chapter 34.

C.4A · istft

Identity (q, a, t, k). Public research-manifest route `komorebi_math.signals.istft`. Reflected implementation `komorebi_math.signals.time_frequency.istft`. No root, stable, or beta facade exports this domain-only name in the reference manifest. The `komorebi_math.signals` route is governed by `[RESEARCH]` policy `pre-beta-additive`. This domain route does not enlarge the frozen stable compatibility surface. Manifest kind `function`. Profile `C4-TIME-FREQUENCY`.

Manifest signature (s).

```
(transform: 'STFTResult', *, synthesis_window: 'Any | None' = None, length: 'int | None' = None, tolerance: 'float'
   ↪ = 1e-11) -> 'ComputationResult[np.ndarray]'
```

Definition. Invert a `STFTResult` by normalized finite overlap-add.

Contract (D, C, H, R, X). Input is a finite one-dimensional signal. Frame length, hop length, and FFT length must be positive, with the hop no larger than the frame and the FFT no shorter than the frame. One-sided transforms require real input. Boundary, centering, padding, detrending, and scaling choices are explicit. Detrended transforms are intentionally noninvertible. Inverse synthesis requires a nonzero overlap profile.

Guarantees (E, P, B, K). Framing metadata records every finite pad, start, and coverage convention. STFT coefficients use NumPy FFT normalization. Invertible configurations reconstruct the original finite record to numerical tolerance through normalized overlap-add. Spectrogram values are nonnegative for magnitude and power forms. Runtime is proportional to the number of frames times the FFT cost.
